The ores, as alteration continues, graduate into true oxides of manganese. A kind from Pesillo (called *Pesillite* by Huot, Min., 1841) has lost nearly all of the silica in the change.

A series of alteration products of rhodonite from North Carolina and Rhode Island have been analyzed by W. N. De Regt, cf. Chester, Jb. Min., **1**, 187, 1888.

**Artif.**—Formed by Bourgeois in crystals by fusing equal equivalents of silica and manganese dioxide, Bull. Soc. Min., **6**, 64, 1883. Also by Gorgeu, ibid., **10**, 264, 1887; described by Vogt from the iron-works at Westanfors, Sweden, in Bessemer slags and also with those of spiegeleisen. Ak. H. Stockh., Bihang, **9**, 29, 1884; Arch. Math. Nat., Christ., **30**, 80, 1889.

**Ref.**—[1] Öfv. Ak. Stockh., **42**, No. 6, 159, 1885, and Zs. Kr., **11**, 506, 1886. The position is that suggested by J. D. D. (Min. 225, 1868), which shows the relation to pyroxene; later adopted by Groth, Tab. Ueb., **58**, 102, 1874, and Flink.

[2] Cf. Dbr., Pogg., **94**, 396, 1855; Greg, Phil. Mag., **4**, 196. 1856; Kk., **4**, 174; Dx., Min., **1**, 68, 1862; Sjögren, Pajsberg, G. För. Förh., **5**, 259, 1880; Flink. l. c., who gives many new forms. [3] Pirsson, Franklin Furnace, N. J., Am. J. Sc., **40**, 484, 1890. [4] E. S. D., Franklin.

HYDRORHODONITE. Hydrorodonit *N. Engström*, G. För. Förh., **2**, 468, 1875. Massive; crystalline. Cleavage easy in one direction. H. = 5–6. G. = 2·70. Luster vitreous. Color red-brown Streak brownish white. Translucent, in thin splinters transparent. Analysis, Engström:

$SiO_2$ 44·07 MnO 30·83 FeO 1·04 CaO 3·60 MgO 6·98 $Li_2O$ 1·23 $Na_2O$ 0·39 $H_2O$ 11·84 = 99·98

A second analysis gave similar results. Soluble in hydrochloric acid with the separation of silica. From Långban, Wermland, Sweden. This may be a hydrated rhodonite.

KLIPSTEINITE. Schwarz-Braunsteinerz von Klapperud *Klapr.*, Beitr., **4**, 137, 1807 = Opsimose *Beud.*, Tr., 187, 1832. Vattenhaltigt Manganoxidsilikat *Bahr*, Öfv. Ak. Stockh., **7**, 242, 1850. Klipsteinite *Kbl.*, J. pr. Ch., **97**, 180, 1866.

Amorphous. Compact. H. = 5–5·5. G. = 3·5. Luster dull to submetallic. Color dark liver-brown to black. Streak reddish brown or yellowish brown. Opaque. Analyses: 1, Bahr, l. c. 2, v. Kobell, l. c.:

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | MnO | MgO | CaO | $H_2O$ | |

[a] Incl. 10·91 $Mn_2O_3$.

**Pyr., etc.**—B.B. fuses at 2·7 to a black magnetic globule, and with the fluxes gives reactions for iron and manganese. Unacted upon by acids.

**Obs.**—Occurs in distinct crystals at Arendal, in Norway, associated with epidote and massive garnet; in the syenite of Sutherland, Scotland, but falsely reported from the Shetlands (Heddle); at Herbornseelbach, Nassau, implanted upon a massive ferruginous quartz; at Baveno, Italy, in cavities in granite; Devonshire, England.

In the United States it is said to coat crystals of feldspar, at Gouverneur, St. Lawrence Co., N. Y. Small black polished crystals coating mica slate, or micaceous gneiss, at Athol, Mass., referred by Shepard to babingtonite, may possibly belong here. but see 5th Ed., p. 228.

It was named after Dr. Wm. Babington (1757–1833).

**Artif.**—Observed in crystals in slag at the Bessemer steel manufacture at Hoerde; the composition (anal. 4) varies somewhat widely from that of the natural mineral; also in cavities in a roasted iron ore from Finspong, Vogt, Ak. H. Stockh., Bihang, 9, No. 1, 37, 1884.

**Ref.**—[1] Arendal, Pogg., **94**, 402, 1855; cf. rhodonite. See also Lévy, l. c.; Dx., Min., 1, 73, 1862; Rath, Baveno, Pogg., **135**, 583, 1868; Id., Nassau, Pogg., Erg., **5**, 420, 1871; Schrauf, Atlas, xxx, 1871.

---

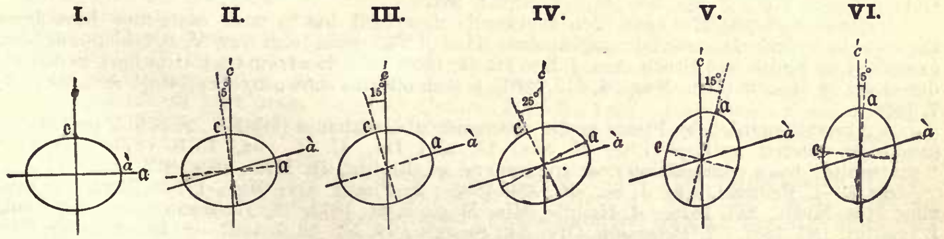
The AMPHIBOLE GROUP embraces a number of species which, while falling in different systems, are yet closely related in form—as shown in the common prismatic cleavage of 54° to 56°—also in optical characters and chemical composition. As already noted (see p. 345), the species of this group form chemically a series parallel to that of the closely allied Pyroxene Group, and between them there is a close relationship in crystalline form and other characters. The amphibole group, however, is less fully developed, including fewer species, and those known show less variety in form.

The chief distinctions between pyroxene and amphibole proper are the following: prismatic angle with pyroxene 87° and 93°; with amphibole 56° and 124°; the prismatic cleavage being much more distinct in the latter. With pyroxene, crystals usually short prismatic and often complex, structure of massive kinds mostly lamellar or granular; with amphibole, crystals chiefly long prismatic and simple, columnar and fibrous massive kinds the rule. The specific gravity of most of the pyroxene varieties is higher than of the like varieties of amphibole. In composition of corresponding kinds, magnesium is present in larger amount in amphibole (Ca : Mg = 1 : 1 in diopside, = 1 : 3 in tremolite); alkalies more frequently play a prominent part in amphibole. Cf also pp. 388, 390.

The optical relations of the prominent members of the group, as regards the position of the axes of light-elasticity, is exhibited by the following figures (after Cross); compare p. 346 for a similar representation for the corresponding members of the pyroxene group.



I. Anthophyllite. II. Glaucophane. III. Tremolite, etc. IV. Hornblende. V. Arfvedsonite (?). VI. Riebeckite (?).

### *a. Orthorhombic Section.*

**337. ANTHOPHYLLITE.** Anthophyllit *Schumacher*, Verzeichn., 96, 1801. Antophyllit *Karst.*, Tab., 32, 1808. Anthogrammit *Breith.*, Char., 29, 1820. Antholith *Breith.*, Uib., 38, 1830. Kupfferit *R. Hermann*, Bull. Soc. Nat. Moscou, **35**, 243, 1862.

**337A.** GEDRITE *Dufrenoy*, Ann. Mines, **10**, 582, 1836.

Orthorhombic. Axial ratio $\breve{a} : \bar{b} = 0{\cdot}51375 : 1$, Penfield[1]. Prismatic angle, $mm''' = 54^\circ 23'$. Crystals rare, habit prismatic but prisms not terminated. Commonly lamellar, or fibrous massive; fibers often very slender. Also in aggregations of prisms, like actinolite.

Cleavage: prismatic, perfect; *b* less so; *a* sometimes distinct. H. = 5·5–6. G. = 3·1–3·2. Luster vitreous, somewhat pearly on the cleavage-face. Color brownish gray, yellowish brown, clove-brown, brownish green, emerald-green, sometimes metalloidal. Streak uncolored or grayish. Transparent to subtranslucent.

Anthophyllite is usually optically + (Dx., anal. 2); also optically + for red, — for yellow, green (Pfd., anal. 1). Ax. pl. always $\parallel b$. $Bx_a$ usually $\perp c$; also $\perp c$ for red, $\perp a$ for yellow, green. Axial angles and indices:

Kongsberg[2] (anal. 2) $2H_{o.r} = 117^\circ 26'$ $2H_{o.y} = 116^\circ 26'$ $\therefore$ $2V_{o.r} = 99^\circ 58'$ $\beta_r = 1{\cdot}636$ Dx.
" (other sections) $2H_{o.r} = 110^\circ 49', 117^\circ 18'$, $2H_{o.y} = 112^\circ 4'$, $2H_{o.bl} = 109^\circ 5', 111^\circ 5\frac{1}{2}'$

Franklin, N. C.[1] (anal. 1) section $\parallel a$ $2H_r = 87^\circ 31'$ $2H_y = 85^\circ 45'$ $2H_{gr} = 83^\circ 44$
" $\parallel c$ $2H_r = 87^\circ 24'$ $2H_y = 88^\circ 5'$ $2H_{gr} = 88^\circ 28'$

$\therefore$ $2V_r = 90^\circ 4'$ $2V_y = 88^\circ 46'$ $2V_{gr} = 87^\circ 28'$ and $\beta_r = 1{\cdot}6276$ $\beta_y = 1{\cdot}6353$ $\beta_{gr} = 1{\cdot}6495$
Also, measured $\beta_y = 1{\cdot}6301$ $\gamma_y = 1{\cdot}6404$ $\therefore$ $\alpha_y = 1{\cdot}6288$.

Gedrite from Fiskernäs is optically —. Axial angles and indices, Ussing[3]:

$2H_{a.r} = 89^\circ 24'$ $2H_{a.y} = 89^\circ 6'$ $2H_{a.gr} = 88^\circ 45'$
$\beta_r = 1{\cdot}6358$ $\gamma_r = 1{\cdot}6439$ $\therefore$ $\alpha_r = 1{\cdot}623$ $2V_r = 78\frac{1}{2}^\circ$.

**Comp., Var.**—$(Mg,Fe)SiO_3$, corresponding to enstatite-bronzite-hypersthene in the pyroxene group. Aluminium is sometimes present in considerable amount. There is the same relation in optical character between anthophyllite (+) and gedrite (—) as between enstatite and hypersthene.

**Var.**—1. ANTHOPHYLLITE, Mg : Fe = 4 : 1, 3 : 1, etc. For 3 : 1, the percentage composition is: Silica 55·6, iron protoxide 16·6, magnesia 27·8 = 100. In anal. 2, Mg : (Fe + Mn + Ca + $H_2$) = 3 : 1 nearly, the water is here chemically combined. Anthophyllite sometimes occurs in forms resembling asbestus.

In *Kupfferite*, the magnesia predominates largely; it thus seems to correspond more nearly to an enstatite; a little chromium gives it a deep green color.

2. *Aluminous*, GEDRITE. Iron is present in larger amount, and also aluminium; it hence corresponds nearly to a hypersthene, some varieties of which are highly aluminous (cf. anals., p. 350); the aluminium may be present as $MgAl_2SiO_6$. The gedrite from Bamle has $mm''' = 54^\circ 40'$ (Dx.), that of Fiskernäs, $mm''' = 55^\circ 12'{\cdot}4$ (Ussing).

*Thalackerite* Breith. is an anthophyllite from Greenland, having a metalloidal luster $\parallel b$. Optically +. $2H_{o.r} = 117^\circ 35'$ Dx., N. R., 32, 1867.

*Hydrous anthophyllites* have been repeatedly described, but in most cases they have been shown to be hydrated monoclinic amphiboles. That of Thomson, from New York Island, has been examined by Smith and Brush, Am. J. Sc., **16**, 49, 1853. Another from Glen Urquhart, Scotland, described by Heddle (Min. Mag., **4**, 213, 1881), is actinolite, as shown by Lcx., Bull. Soc. Min., **9**, 7, 1886.

A mineral regarded by Pisani as the *snarumite* of Breithaupt (5th Ed., p. 316) is probably a somewhat altered anthophyllite, cf. anal 13, and Dx., C. R., **84**, 1510, 1877. Another "snarumite" has a composition near spodumene, cf. Breith., Jb. Min., 820, 1872.

**Anal.**—1, Penfield, Am. J. Sc., **40**, 394, 1890. 2, Pisani, Dx. Min., **1**, 536, 1862. 3, Brezina, Min. Mitth., 247, 1874. 4, Heddle, Min. Mag., **3**, 21, 1879. 5, Hermann, l. c. 6, Pisani, L'Institut, 190, 1861. 7, Petersson, Öfv. Ak. Stockh., **39**, No. 10, 7, 1882. 8, Rosenius, Zs. Kr., **2**, 498, 1878. 9, Stadius, ibid. 10, Lechartier, Dx., N. R., 32, 1867. 11, Ussing, Öfv. Ak. Stockh., **46**, 29, 1889, Zs. Kr., **15**, 609, 1889. 12, 13, Pisani, C. R., **84**, 1510, 1877.

[a] $Cr_2O_3$. [b] NiO. [c] Incl. 0·44 $Fe_2O_3$. [d] $Na_2O$.

A "kupfferite" analyzed by Lorenzen from Greenland is shown by Ussing to be bronzite (anal. 5, p. 347).

**Pyr., etc.**—B.B. fuses with difficulty to a black magnetic enamel; with the fluxes gives reactions for iron; unacted upon by acids.

**Obs.**—Anthophyllite occurs in mica schist with hornblende and mica in thin and long plates and fibers near Kongsberg in Norway, and with gray cobalt near Modum; in the spherical mica aggregates at Hermannschlag, Moravia; probably in the gabbro of the Lizard, Cornwall (Teall). In the U. S., at the Jenks corundum mine, Franklin, Macon Co., N. C.

Named from *anthophyllum*, *clove*, in allusion to the clove-brown color, as Schumacher states.

*Kupfferite* is from a graphite mine in the Tunkinsk Mts., near L. Baikal. The analysis here given is from a mineral of similar kind from near Miask, in the Ilmen Mts. The former has not been analyzed. Koksharov has also found it near the Sanarka river, Ural. Named after the Russian crystallographer and physicist Adolf Kupffer (1799–1865).

The original *gedrite* is from the valley of Héas, near Gèdres, France, and contains microscopic black spinels (*picotite*). Similar aluminous anthophyllites have been observed in crystalline schists from other localities, as at Hilsen near Snarum, also Kragerö, Bamle, in Norway; Stansvik near Helsingfors, Finland (Sjögren); also Fiskernäs, Greenland.

Piddingtonite *Haidinger*, Ber. Ak. Wien, **41**, 251, 1860. The ash-gray mass of the meteorite of Shalka, in Bancoorah, consisting in part of grains having two easy cleavages inclined to one another 70°, with H. = 6·5; G. = 3·412 Haid., 3·66 Piddington; and fracture resinous, and containing small embedded grains of chromite. Hauer obtained: $SiO_2$ 57·66, $Al_2O_3$ *tr.*, FeO 20·65, MgO 19·00, CaO 1·53 = 98·84, which is nearly the composition of anthophyllite. The meteorite was first described by H. Piddington in the J. Asiat. Soc. Bengal, **20**, 299, 1852.

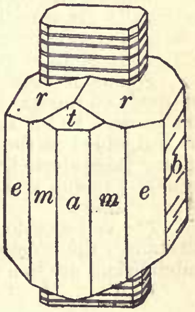
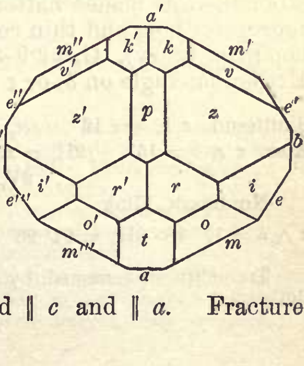


Figs. 5–7, 11, Russell, N. Y. 8, 9, Pierrepont, N. Y. 10, Rossie, N. Y. 12, DeKalb, N. Y. Figs. 5–12, Penfield. 13, A dark green amphibole enclosing, in parallel position, a pale green pyroxene, Russell, N. Y., G. H. Williams.

Twins[7]: (1) tw. pl. *a*, common as contact-twins; rarely polysynthetic[4]. (2) *c*, as tw. lamellæ, occasionally producing a parting analogous to that more common with pyroxene (f. 13). Crystals commonly prismatic, with *m* short (f. 1, 2), or elongated (f. 5, etc.); usually terminated by the low clinodome, *r*, sometimes by *r* and *p* equally developed and then suggesting rhombohedral forms (as of the low terminal rhombohedron of tourmaline), since the angles *rr'* and *pr* approximate to each other; the form *a* not very common. Also columnar or fibrous, coarse or fine, fibers often like flax; rarely lamellar; also granular massive, coarse or fine, and usually strongly coherent, but sometimes friable.

**14.**



Cleavage: *m* highly perfect; *a*, *b* sometimes distinct. Parting, due to twinning, sometimes observed ∥ *c* and ∥ *a*. Fracture subconchoidal, uneven. Brittle. H. = 5–6. G. = 2·9–3·4, varying with the composition. Luster vitreous to pearly on cleavage-faces; fibrous varieties often silky. Color between black and white, through various shades of green, inclining to blackish green; also dark brown, rarely yellow, pink, rose-red. Streak uncolored, or paler than color. Sometimes nearly transparent; usually subtranslucent to opaque.

Pleochroism strongly marked in all the deeply colored varieties, as described beyond. Absorption usually $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically $-$, rarely $+$. Ax. pl. ∥ *b*. Extinction-angle on *b*, or $\mathfrak{c} \wedge \dot{c} = +15°$ to $18°$ in most cases, but varying from about 0° up to 37°; hence also $Bx_a \wedge \dot{c} = -75°$ to $-72°$, etc. Dispersion $\rho < v$. Axial angles, variable; see under the varieties below.

**Comp., Var.**—In part a normal metasilicate of calcium and magnesium, usually with iron, also manganese, and thus in general analogous to the pyroxenes. The alkali metals, sodium and potassium (and hydrogen), also present, and more commonly so than with pyroxene. In part also aluminous, corresponding to the aluminous pyroxenes. Titanium sometimes is present and also rarely fluorine in small amount.

The aluminium is in part present as $NaAl(SiO_3)_2$, but many amphiboles containing aluminium or ferric iron are more basic than a normal metasilicate; they may sometimes be explained as containing $\overset{II}{R}(Al,\overset{III}{Fe})_2SiO_6$ (cf. Tschermak)[8]; but the exact nature of the compound is often doubtful. Tschermak has shown reason for writing the amphibole formulas as double the corresponding ones for pyroxene. Thus, for most tremolite and actinolite, Ca : Mg(Fe) = 1 : 3, and hence tremolite is $CaMg_3Si_4O_{12}$, while diopside is $CaMgSi_2O_6$, etc.

Rammelsberg has shown that the composition of most aluminous amphiboles may be expressed in the general form $m RSiO_3 . n Al_2O_3$. While Scharizer, modifying this view, proposes to regard the amphiboles as molecular compounds of $Ca(Mg,Fe)_3Si_4O_{12}$ (actinolite), and the orthosilicate $(\overset{I}{R}_2,\overset{II}{R})_3\overset{III}{R}_2Si_3O_{12}$, for which he uses Breithaupt's name *syntagmatite* (syntagmit Rg.), originally given to the Vesuvian hornblende. The Jan Mayen amphibole, anal. 117, approximates in composition to syntagmatite in this sense. Cf. Jb. Min., **2**, 143, 1884, also Rg., Min. Ch., Erg., p. 37 *et seq.*, 1886.

The name *amphibole*, proposed by Haüy, has the precedence, because Haüy first rightly appreciated the species, as he had done for pyroxene, and gave it, and not any of its varieties, the name. In his Traité, in 1801, he brought together *hornblende* and *actinolite;* and by 1809 he had added to the group the third prominent variety, *tremolite;* while in all other works not taking their views from him, these three minerals still stood as distinct species. *Asbestus* was annexed to the series by Hausmann in 1813, though kept separate long afterward by many other authors.

The varieties depend chiefly upon composition; in part also, but less fundamentally, upon structure; the prominent kinds are properly sub-species, as was true with the pyroxenes, and the subdivisions are to a considerable extent the same here as there.

## I. *Containing little or no Aluminium.*

TREMOLITE. Grammatite, nephrite pt. *Calcium-magnesium amphibole.* Formula $CaMg_3Si_4O_{12}$ = Silica 57·7, magnesia 28·9, lime 13·4 = 100. Ferrous iron, replacing the magnesium, is present only sparingly, up to 3 p. c. Colors white to dark gray. In distinct crystals, either long-bladed or short and stout; often in thin blades flattened ∥ $\dot{b}$ by the oscillatory repetition of the prism. In aggregates long and thin columnar, or fibrous; also compact granular massive (see nephrite, below). G.=2·9–3·1. Sometimes transparent and colorless. Optically $-$. Extinction-angle on *b*, or $\mathfrak{c} \wedge \dot{c} = +16°$ to $18°$, hence $Bx_a \wedge \dot{c} = -74°$ to $-72°$.

**Skutterud** $\mathfrak{c} \wedge \dot{c} = 16°$ $\alpha_y = 1·6065$ $\beta_y = 1·6233$ $\gamma_y = 1·6340$ $2V_y = 81° 22'$ **Pfd**
**Also** $\mathfrak{c} \wedge \dot{c} = 15°$ $2H_r = 99°–100°$ $2H_y = 100°–101°$ $\beta_r = 1·620$ $\beta_y = 1·622$
$\therefore$ $2V_r = 87° 22'$ $2V_y = 88° 16'$ **Dx.**

**Nordmark, Flink:**

$\mathfrak{c} \wedge \dot{c} = 17° 18'$ $2H_y = 94° 26'$ $\beta_r = 1·616$ **Li** $\beta_y = 1·618$ **Na** $\beta_{gr} = 1·620$ **Tl** $\therefore$ $2V_y = 84° 9'$

Tremolite was named by Pini from the Tremola valley on the south side of the St. Gothard.

*Grammatite* (from γραμμή, *a line*) alludes to a line in the direction of the longer diagonal seen by Haüy on transverse sections of some crystals. It was substituted for tremolite by Haüy, without reason, and does not deserve recognition.

*Nordenskiöldite*, from Ruscola, near Lake Onega, is tremolite.

*Raphilite*, from Lanark in Canada, is probably also tremolite.

*Hexagonite* from Edwards, St. Lawrence Co., N. Y., is a pink tremolite containing a small amount of manganese (anals. 12, 13); it was described as hexagonal, but its true character was shown by Koenig.

Some *nephrite* and *asbestus* (see below) belong here.

ACTINOLITE. Strahlstein *Germ*. *Calcium-magnesium-iron amphibole*. Formula $Ca(Mg,Fe)_3Si_4O_{12}$. Color bright green and grayish green. In crystals, either short- or long-bladed, as in tremolite; columnar or fibrous; granular massive. G. = 3–3·2. Sometimes transparent. The variety in long bright-green crystals is called *glassy actinolite;* the crystals break easily across the prism. The fibrous and radiated kinds are often called *asbestiform actinolite* and *radiated actinolite*. Actinolite owes its green color to the ferrous iron present.

Pleochroism distinct, increasing as the amount of iron increases, and hence the color becomes darker: $\mathfrak{c}$ emerald-green, $\mathfrak{b}$ yellow-green, $\mathfrak{a}$ greenish yellow. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$ Zillerthal, Tschermak. Optically —. Extinction-angle on $b$ or $\mathfrak{c} \wedge \dot{c} = +15°$ and $Bx_a \wedge \dot{c} = -75°$. Axial angles, Dx.:

St. Gothard $2H_{a.r} = 90°$ to $91°$ $\beta_r = 1·626$ $2V_r = 79° 38'$
" " $2H_{a.y} = 91°$ $\beta_y = 1·629$ $2V_y = 80° 4'$
Zillerthal $\alpha_y = 1·611$ $\beta_y = 1·627$ $\gamma_{gr} = 1·636$ $\gamma - \alpha = 0·025$ Lévy-Lcx.

Named actinolite from ἀκτίν, *a ray*, and λίθος, *stone*, a translation of the German *Strahlstein* or *radiated stone*. Name changed to *actinote* by Haüy, without reason.

NEPHRITE. Jade pt. Cacholong pt. A tough, compact, fine-grained tremolite (or actinolite), breaking with a splintery fracture and glistening luster. H. = 6–6·5. G. = 2·96–3·1. Named from a supposed efficacy in diseases of the kidney, from νεφρός, *kidney*. It varies in color from white (tremolite) to dark green (actinolite), in the latter iron protoxide being present up to 6 or 7 p. c. The latter kind sometimes encloses distinct prismatic crystals of actinolite (anal. 40). A derivation from an original pyroxenic mineral has been suggested in some cases (Arzruni, Traube).

Nephrite or jade was brought in the form of carved ornaments from Mexico or Peru soon after the discovery of America. Del Rio, in his Mexican Mineralogy (1795), mentions no Mexican locality. A similar stone comes from Eastern Asia, New Zealand, and Alaska as noted beyond. See also pp. 371, 397.

ASBESTUS. Asbestos. Asbest *Germ*. Tremolite, actinolite, and other varieties of amphibole, excepting those containing much alumina, pass into fibrous varieties, the fibers of which are sometimes very long, fine, flexible, and easily separable by the fingers, and look like flax. These kinds are called *asbestus* (fr. the Greek for *incombustible*). Pliny supposed it a vegetable product, although good for making *incombustible* cloth, as he states. The amianthus of the Greeks and Latins was the same thing; the word meaning *undefiled*, and alluding to the ease of cleaning the cloth by throwing it into the fire. The colors vary from white to green and wood-brown. The name *amianthus* is now applied usually to the finer and more silky kinds. Much that is called asbestus is *chrysotile*, or fibrous serpentine (Serpentinasbest *Germ.*), it containing 12 to 14 p. c. of water, see p. 670.

Friederici has described varieties of asbestus in which alkalies are prominent (anals. 84, 85); one was blue in color and resembled crocidolite.

An asbestiform mineral from Franklin Furnace, N. J., has been analyzed by Koenig; he gives: 4·8 p. c. MnO, 4·6 ZnO (also 1·70 MnO, 7·10 ZnO in another sample), Proc. Ac. Philad., 47, 1887. Some other asbestiform amphiboles are noted below. It is possible that some asbestus may properly belong to the pyroxene group; cf. ægirite, p. 366, and crocidolite, p. 400.

The following are related to asbestus:

*Mountain leather* is in thin flexible sheets, made of interlaced fibers; and *mountain cork* (Bergkork) the same in thicker pieces; both are so light as to float on water, and they are often hydrous, color white to gray or yellowish. *Mountain wood* (Bergholz, Holzasbest, *Germ.*) is compact fibrous, and gray to brown in color, looking a little like dry wood.

*Byssolite* (Amianthoid, asbestoid) fr. Bourg d'Oisans in Dauphiny, is of an olive-green color, coarse and stiff fibrous; it is stated to contain a considerable amount of manganese. The name is often given to similar varieties of amphibole, not necessarily manganesian.

SMARAGDITE. A thin-foliated variety of amphibole, near actinolite in composition but carrying some alumina. It has a light grass-green color, resembling much common green diallage. As early urged by Rose it has at least in many cases been derived from pyroxene (diallage) by uralitization, see uralite, below. It retains much of the structure of the diallage and also often encloses remnants of the original mineral. It forms, along with whitish or greenish saussurite, a rock called saussurite-gabbro, the euphotide of the Alps. The original mineral is from Corsica, and the rock is the *corsilyte* of Pinkerton, and the *verde di Corsica duro* of the arts.

Uralite *Rose*, Pogg., **22**, 321, 329, 1831; **27**, 97, 1833; **31**, 609, 1831. Traversellite pt. Pyroxene altered to amphibole. The crystals, when distinct, retain the form of the original mineral, but have the cleavage of amphibole. The change usually commences on the surface, transforming the outer layer into an aggregation of slender amphibole prisms, parallel in position to each other and to the parent pyroxene. When the change is complete the entire crystal is made up of a bundle of amphibole needles or fibers. The color varies from white (tremolite), as in the Canaan, Conn., crystals, to pale or deep green, the latter the more common. In composition uralite appears to conform nearly to actinolite, as also in optical characters (Dx.). The most prominent change in composition in passing from the original pyroxene (cf. anals. below) is that corresponding to the difference existing between the two species in general, that is, an increase in the magnesium and decrease in calcium The change, therefore, is not strictly a case of paramorphism, although usually so designated.

Uralite was originally described by Rose from a green porphyritic rock at Mostovaya, near Ekaterinburg, and at Kaminskaya, near Miask, in the Ural. It has since been observed from many localities. The microscopic study of rocks has shown the process of "uralitization" to be very common, and some authors regard many hornblendic rocks and schists to represent altered pyroxenic rocks on a large scale. The following (1, 2, 5, 7, 9) are analyses of uralite: 1, Rath, Pogg., **95**, 558, 1855. 2, Rg., Min. Ch., 421, 1875; also Kudernatsch, Pogg., **37**, 586, 1836. Analyses 3–5, by Harrington (Geol. Canada, p. 21, 1879), give the composition of the glassy green central portion of a pyroxene crystal (3); of the dull gray zone surrounding this (4); and finally of the amphibole forming the exterior (5). 6, 7 are analyses by Richter and Scheerer (Pogg., **84**, 383, 1851) of the diopside (6) from Reichtenstein and of a fibrous actinolite (7) derived from it. 8, 9, by Dahms (Jb. Min., Beil., **7**, 99, 1890), show the change of composition from the original diallage (8) to the resulting amphibole (9). 10, 11, by Rammelsberg (Ber. Ak. Berlin, 243, 1862), give the composition of diopside (10) and tremolite (11) associated together in granular limestone at Gulsjö, Wermland, Sweden, the latter apparently derived from the former.

[a] CuO

It is interesting to compare in this connection the analyses of green pyroxene (anal. 68, p. 360) and amphibole (anal. 112, p. 396) associated in parallel position at Vesuvius by Rath; also of a similar occurrence by Hawes, from Edenville, anal. 32, p. 359, and anal. 108, p. 396.

Cummingtonite. Amphibole-Anthophyllite. *Iron-Magnesium-Amphibole.* Des Cloizeaux has used the name amphibole-anthophyllite for certain varieties of amphibole resembling anthophyllite and essentially identical with it in composition, but optically proved to be monoclinic. For that from Kongsberg (anal. 89) he finds $mm''' = 54° 48'$, and $\mathfrak{c} \wedge \dot{c} = 15°$ to $16°$. Also:

$$2H_{o.r} = 120° 43\tfrac{1}{2}' \quad 2H_{o.y} = 120° 2\tfrac{1}{2}' \quad 2H_{o.bl} = 118° 31\tfrac{1}{2}' \quad \beta_r = 1·638 \quad \therefore \quad 2V_a = 77° 52'$$

For that from Greenland (anal. 90) $\mathfrak{c} \wedge \dot{c} = 16°$ to $17°$:

$$2H_{o.r} = 119° 43' \quad 2H_{o.bl} = 118° 22'. \quad \text{Also } 2H_{o.r} = 119° 27' \quad 2H_{o.bl} = 117° 24'.$$

The original *cummingtonite* is nearly the same, but contains more iron and less magnesium (anal. 92, 93). It is gray to brown in color; usually fibrous or fibro-lamellar, often radiated. G. = 3·1–3·32. Named from the locality, Cummington, Mass. The name has also been used for a partially altered rhodonite, which Hermann erroneously called a "Mangan-amphibol."

*Antholite.* This name (Kenng., Ueb., 6, 1859, 1860; Dana, Min., 5th Ed., p. 234) has been used for certain asbestiform amphiboles containing 26 to 31 p. c. MgO and 12·6 to 9 p. c. FeO without lime and alumina. Cf. anals. 31–33, 5th Ed., p. 237.

**DANNEMORITE.** *Iron-Manganese Amphibole.* Color yellowish brown to greenish gray. Columnar or fibrous, like tremolite and asbestus. Contains iron and manganese. In thin pieces B.B. fuses to a dark slag.

*Asbeferrite* of Igelström is similar; it is grayish white to ash-gray, and like a gray asbestus; in acids not soluble (anal. 95).

*Silfbergite.* Like amphibole in form, cleavage, and twinning (∥ *a*). H. = 5·5. G. = 3·446. Color dark yellow to brownish gray. Pleochroism distinct. Extinction-angle on *b*, 13° 45′. Shown by Bertrand to belong here with also the following mineral. From Vester Silfberg, Wermland, Sweden. See anal. 96.

*Hillängsite.* Near dannemorite, cf. anal. 97. Resembles anthophyllite. Optically −. Occurs with garnet, magnetite, and igelströmite at the iron mine of Hilläng, parish of Ludvika, Dalarne, Sweden.

**GRÜNERITE.** *Iron-Amphibole.* Asbestiform or lamellar-fibrous. Luster silky; color brown; G. = 3·713. Formula $FeSiO_3$. Optical properties those of amphibole, according to Des Cloizeaux (Min., 1, 59, 1862). Lévy-Lcx. give the extinction-angle as 11° to 15°. Pleochroism feeble. Occurs in metamorphic schists in the Dept. du Var, France. Grüner's analysis gave: $SiO_2$ 43·9, $Al_2O_3$ 1·9, FeO 52·2, MgO 1·1, $H_2O$ 0·5 = 99·6. This amphibole needs further study.

**RICHTERITE.** *Sodium-Magnesium-Manganese Amphibole.* In elongated crystals, seldom terminated. Observed forms, Långban:

*a, b, c, n, m, e, p, r, o, z, k*? (cf. p. 386). Measured angles: *mm‴* = 56° 7′, *rr′* = 31° 18′, *mr* = 68° 29′, *mp* = 77° 28′. See Flink, Ak. H. Stockh., Bihang, 13 (2), No. 7, 82, 1888.

G. = 3·09. Color brown, yellow, rose-red. Transparent to translucent. $\mathfrak{c} \wedge \dot{c} = +17°$ Flink, 20° and $\beta_y = 1·63$ Lévy-Lcx.

From Pajsberg and Långban, Sweden. Characterized by the presence of manganese and alkalies in relatively large amount. See anals. 98, 99. Michaelson gave for a Långban amphibole, with G. = 3·09, Öfv. Ak. Stockh., 20, 197, 1863:

$SiO_2$ 54·15 $Al_2O_3$ 0·52 $Fe_2O_3$ 1·77 FeO 2·80 MnO 5·09 MgO 20·18 CaO 6·06 $Na_2O$ 2·77
[$K_2O$ 6·37 ign. 0·12 = 99·83

The above is the richterite of Igelström and Flink. The character of the original mineral named by Breithaupt is doubtful. Breithaupt describes it as occurring in acicular crystals, affording the prismatic angle 46° 22′; with G. = 2·826; color isabella-yellow, rarely pale yellowish brown; B.B. very fusible. See ASTOCHITE, p. 1027.

**MARMAIROLITE** *N. O. Holst*, G. För. Förh., 2, 530, 1875. In very fine crystalline needles. H. = 5. G. = 3·07. Color pale yellow. Powder white. Transparent. Analysis (mean of several):

$SiO_2$ 56·27 FeO 2·03 MnO 4·86 MgO 21·36 CaO 6·33 $K_2O$ 1·89 $Na_2O$ 5·94 ign. 0·90=99·58

Formula approximately $RSiO_3$. B.B. fuses with some difficulty to an opaque bead. Not attacked by acids. Occurs with schefferite in a brownish manganesian limestone (containing 6·56 MnO and 1·35 PbO) at Långban, Wermland, Sweden. Named from *μαρμαίρειν, to glisten.* Groth suggests that this may be a massive form of richterite.

*Breislakite.* Occurs in wool-like forms at Vesuvius and Capo di Bove. It was made a variety of pyroxene by Chapman (Phil. Mag., 37, 444, 1850), but Lasaulx (Jb. Min., 380, 1878) shows that it has the form and optical characters of amphibole. The color is dark brown to black, and the pleochroism strongly marked. Blowpipe tests prove the presence of iron and, in less amount, of manganese, hence it is inferred that it may belong near richterite. Named after S. Breislak, an Italian geologist (1748–1826).

### II. *Aluminous.*

**ALUMINOUS AMPHIBOLES.** Contain alumina or ferric iron, and usually both, with ferrous iron (sometimes manganese), magnesium, calcium, and alkalies. The kinds here included range from the light colored *edenite,* containing but little iron, through the light to dark green *pargasite,* to the dark colored or black *hornblende,* the color growing darker with increase in amount of iron. Extinction-angle variable, from 0° to 37°, see below. Pleochroism strong. Absorption usually $\mathfrak{c} < \mathfrak{b} < \mathfrak{a}$.

**EDENITE.** *Aluminous Magnesium-Calcium Amphibole.* Color white to gray and pale green, and also colorless; G. = 3·0–3·059. Resembles anthophyllite and tremolite. Named from the locality at Edenville, N. Y. To this variety belong various pale-colored amphiboles, having less than 5 p. c. of iron oxides.

*Koksharovite* is a variety from the neighborhood of L. Baikal named after the Russian mineralogist, N. von Koksharov. See anal. 105.

PARGASITE and COMMON HORNBLENDE. Colors bright or dark green, and bluish green to grayish black and black. G. = 3·05–3·47. *Pargasite* is usually made to include green and bluish-green kinds, occurring in stout lustrous crystals, or granular; and *common hornblende* the greenish black and black kinds, whether in stout crystals or long-bladed, columnar, fibrous, or massive granular. But no line can be drawn between them. The extinction-angle on *b*, or $\mathfrak{c} \wedge \dot{c} = +18°$ to 20° chiefly. Pargasite occurs at Pargas, Finland, in bluish green and grayish black crystals. The dark brown to black hornblendes from basaltic and other igneous rocks vary somewhat widely in optical characters, the angle $\mathfrak{c} \wedge \dot{c} = 0°$ to $+10°$ chiefly. They carry both aluminium and ferric iron and also alkalies.

The following table (Tschermak *et al.*) shows the variation in optical characters for the amphiboles embraced here; cf. observations on tremolite and actinolite already given, pp. 388, 389.

| | Optical character and extinction-angle on *b* | | Axial angles | | | Pleochroism | | |
|---|---|---|---|---|---|---|---|---|
| | | $\mathfrak{c} \wedge \dot{c}$ | | | | $\mathfrak{c}$ | $\mathfrak{b}$ | $\mathfrak{a}$ |
| *Pargasite* | + | +18° | $2E_r=107° 30'$ | $\beta=1·64$ | $2V=59°$ | grn.-blue | emd.-grn. | grn.-yw. |
| *Common Hornblende.* | | | | | | | | |
| Volpersdorf | + | 19° 53' | | $\beta_r=1·642$ | $2V_r=85° 4'$ | brown | yellow | yw.-grn. |
| Saualpe | | | | | | | | |
| *Karinthin* | | 17° | | | | grn.-brn. | yw.-brn. | yw.-grn. |
| Franklin, N. J. | | 17° 15' | | | | blue grn. | yw.-grn. | hny.-yw |
| Arendal, *blk.* | | 17° 30' | | | | blk.-brn. | brn.-yw. | blk.-brn. |
| Nordmark | | 12° 34' | | | | | | |
| *Basaltic Hornblende.* | | | | | | | | |
| Jan Mayen | | 0° | | | | orange | orange | black |
| Czernosin | − | 1° 40' | $2H_r= 93° 24'$ | $\beta=1·71$ | $2V_r=79° 24'$ | blk.-brn. | brn.-red | hny.-yw. |
| Aranyer Berg | | 37° 12' | $2E_y= 67° 37'$ | $2H_y=51°·3$ | | grn.-brn. | yw.-brn. | olive-grn. |
| *Gamsigradite* | | 30° | | | | grn.-yw. | yellowish | btl.-grn. |

Wiik obtained for a light green variety (15 to 16 p. c. $Al_2O_3$) $\mathfrak{c} \wedge \dot{c} = 26° 30'$, and for a similar one from Korpo (20 p. c. $Al_2O_3$) $\mathfrak{c} \wedge \dot{c} = 27° 30'$; a black variety from Pargas (12 p. c. $Al_2O_3$) gave 24° 30'. Black hornblende from Sillböle, Finland (4·98 $Al_2O_3$), gave him $\mathfrak{c} \wedge \dot{c} = 18° 30'$.

*Noralite* (5th Ed., p. 236) is a black aluminous iron-calcium amphibole in which magnesium is nearly absent. Anal. 120. From Nora, Westmanland, Brevik, Norway, etc.

*Gamsigradite* contains manganese in considerable amount, anal. 121. Color velvet-black. G. = 3·12. For optical characters see above, and Lcx., Bull. Soc. Min., **10**, 147, 1887. Named from the locality, Gamsigrad in Servia, where it forms with white feldspar a rock called *timazyte*. An amphibole from Franklin Furnace examined by Kloos (anal. 122) belongs near here in composition; it contains both manganese and zinc. G. = 3·352. Color dark leek-green. Optical characters, see above.

*Mangan-amphibol* of Hermann (Cummingtonite *Rammelsberg*, and Hermannite *Kenngott*) is nothing but rhodonite of Cummington, Mass., erroneously analyzed. The error is perpetuated by Rg., Min. Ch., 1875, and Groth, Tab. Ueb., 1889.

*Diastatite* is a black hornblende from Nordmark in Wermland, stated by Breithaupt to have $mm''' = 59° 40'$, and G. = 3·08–3·11.

*Syntagmatite* is the black hornblende of Vesuvius, analyzed by Rammelsberg (anal. 110), in which he found $mm''' = 55° 52'$, G. = 3·272. For Scharizer's use of this name, see p. 388.

Breithaupt has also introduced other names (as *Amphibolus ferrosus*, *A. basalticus*, *A. saxosus*, etc.). His *A. Wallerianus*, or Wallerian, is a black hornblende from Nordmark, supposed to be triclinic. The amphibole from the Saualpe, Carinthia, is *A. Carinthinus* or Carinthine (Karinthin), etc.

*Bergamaskite* is an iron-amphibole containing almost no magnesia. It occurs in a quartzose hornblende-porphyry, from Monte Altino, Province of Bergamo, Italy. Forms acicular crystals, vertically striated, and arranged in parallel or radiated groups; cleavage prismatic, 56°. G. = 3·075. See anal. 123.

*Kaersutite* is a titaniferous amphibole from Kaersut, Umanaks fiord, North Greenland, occurring in a chrysolitic rock. Crystals prismatic, $mm''' = 55° 29'$. G. = 3·04. Color black, brownish by reflected light, streak chocolate-brown. Peculiar in containing a large amount of titanium, anal. 124.

The following analyses, largely recent, exhibit the composition of the various kinds of amphibole from the important localities. Additional (older) analyses are given in 5th Ed., pp. 236 to 239; also Rg., Min. Ch., 1860 and 1875. Cf. also Heddle, Trans. R. Soc., Edinburgh, **28**, 502 *et seq.*, 1878.

**Pyr.**—Essentially the same as for the corresponding varieties of pyroxene, see p. 361.

**Obs.**—Amphibole occurs in many crystalline limestones, and granitic and schistose rocks, and sparingly in serpentine, and volcanic or igneous rocks. Tremolite, the magnesia-lime variety, is especially common in limestones, particularly magnesian or dolomitic; actinolite (also nephrite), the magnesia-lime-iron variety, in steatitic rocks and with serpentine; and dark green and black hornblende, in chlorite schist, mica schist, gneiss, and in various other rocks of which it forms a constituent part; brown to black hornblende occurs in trachyte and other eruptive rocks. Asbestus is often found in connection with serpentine.

*Hornblende-rock*, or *amphibolyte*, consists of massive hornblende of a dark greenish black or black color, and has a granular texture. Occasionally the *green* hornblende, or actinolite, occurs in rock-masses, as at St. Francis, in Canada. *Hornblende-schist* has the same composition as amphibolyte, but is schistose or slaty in structure. It often contains a little feldspar. In some varieties of it the hornblende is in part in minute needles. *Hornblendic granite* contains hornblende in addition to the ordinary constituents of granite, or replacing the mica. *Gneiss* and *mica schist* are often *hornblendic* in the same way. The hornblende in mica schist is usually in prisms, either stout or acicular, which sometimes are aggregated in sheaf-like tufts. The *fasciculite* of Hitchcock is merely this tufted hornblende. *Syenite* is a granitoid rock, containing hornblende along with orthoclase feldspar. *Dioryte* is a similar rock, grayish white to nearly black in color, consisting of hornblende and a triclinic feldspar.

Prominent foreign localities of amphibole are the following; many others have been mentioned in connection with the descriptions of varieties and analyses. *Tremolite* (grammatite) in dolomite at Campolongo in Canton Tessin, Switzerland; also at Orawitza; Rezbánya, Hungary; Gulsjö, Wermland, Sweden; Tromsö, Norway, etc. *Actinolite* in the crystalline schists of the Central and Eastern Alps, especially at Greiner in the Zillerthal; Pfitsch; Zermatt; in fine fibrous form at the Knappenwand, Sulzbachthal, Tyrol, with epidote; Zöblitz in Saxony; Arendal, Norway. *Asbestus* at Sterzing, Zillerthal, and elsewhere in Tyrol; in Savoy; also in the island of Corsica, where it is so abundant that Dolomieu is said to have employed it in packing his minerals; at Dretlitz, Pyrenees. *Rock cork* is obtained in the Zillerthal, Saxony, Portsoy, and Leadhills, where also mountain leather occurs. Bourg d'Oisans, in France, affords a variety of amianthus, composed of fibers having some degree of elasticity; it is the *amianthoide* of Haüy. *Pargasite* at Pargas, Finland; Saualpe in Carinthia. *Hornblende* at Arendal and Kongsberg, Norway; in Sweden and Finland; at Vesuvius; Aussig and Teplitz, Bohemia; in basalt at Wolfsberg near Czernosin; Klotzberg, Bohemia; the Rhöngebirge; Vogelsgebirge; Kaiserstuhl.

*Nephrite*, which in the form of "jade" ornaments and utensils is widely distributed among the relics of early man (see jade, p. 371), is obtained at various points in central Asia. The most important source is that in the Karakash valley in the Kuen Lun Mts. on the southern borders of Turkestan; the exact locality of the quarries, which have been extensively worked by the Chinese, is 7 miles from the Kirghiz encampment of Balakchi, which is 12 miles S.E. of Shahidulla (Stoliczka, Q. J. G. Soc., 30, 568, 1874). Quarries also exist in the Kuen-Lun Mts., to the south of Khotan, which have been known by the Chinese for 2000 years; probably also at other points in the same range (cf. Schlagenweit, Ber. Ak. München, 227, 1873*). Another locality has been described in the same region on the eastern slope of the Pamir on the Raskem-daria, where it has been extensively mined by the Chinese; from this source the material for the tombstone† of Timur (anal. 59) in Samarkand is believed to have been obtained; white "jadeite" (like that of Burma) is mentioned as occurring with it (Nature, 1890). It has also been found at various localities in the government of Irkutsk, eastern Siberia, near L. Baikal, but only as rolled masses in river beds, etc. (cf. Beck and Mushketov, l. c.). Also reported from the province of Yunnan, southern China. In New Zealand it has been much used by the Maoris (called by them Pumamu, Tangiwai, Kawakawa, etc.), and obtained from several points on the west coast of the South Island (Hochstetter, Ber. Ak. Wien, **49** (1), 466, 1864).

Nephrite has been found in Europe as a rolled mass at Schwemmsal near Leipzig; in Swiss Lake habitations and similarly elsewhere. Also an extremely fine-fibrous amphibole closely resembling oriental nephrite (anals. 67–69) occurs in place at Reichenstein and Jordansmühl, Silesia (Traube, l. c.), where it occurs with serpentine and has resulted from the uralitization of a massive pyroxenic rock; further, rolled masses (anals. 65, 66) have been found in the Sannthal and Murthal, Styria, which were probably derived from the neighboring mountains (cf. Berwerth, Ann. Mus. Wien, **3**, 79, 1888).

In America, besides the jade ornaments common in Mexico, South America and Alaska, nephrite has been found in pebbles in gravel bars (Rep. G. Canada, 1887–88) on the Lewis river in the Yukon district, North-west Territory. A mass of a pale green color, translucent to subtransparent and weighing 1¾ lbs., was found in Miles Cañon; another at the Kwikpak mouth of the Yukon. Further, nephrite (anals. 77–80) has been found in place at the Jade Mts., north of the Kowak river, about 150 miles above its mouth (Storey, Clarke). Also found in rolled pebbles and as Indian implements near Lytton in the valley of the Fraser river, Br. Columbia.

In the United States, in *Maine*, black crystals occur at Thomaston, at Moultenboro in syenite; pargasite at Phippsburg and Parsonsfield; radiated or asbestiform actinolite at Unity; tremolite at Thomaston and Raymond. In *N. Hamp.*, black crystals at Franconia. In *Vermont*, glassy and radiated actinolite in the steatite quarries of Windham, Readsboro', and New Fane. In *Mass.*, white crystals of tremolite at Lee; glassy and radiated actinolite at Middlefield and Blandford; radiated actinolite at Carlisle, Pelham, Windsor, Lee, and Great Barrington: black crystals at Chester; asbestus at Brighton, Sheffield, Pelham, Newbury, Dedham; cummingtonite at Cummington and Plainfield. In *Conn.*, in large flattened white crystals and in bladed and fibrous forms (tremolite) in dolomite, at Canaan, between the Falls and the post-office, and also at other places in Litchfield Co.; asbestus at West Farms, Winchester, and Wilton, and with mountain leather at the Milford serpentine quarries.

In *N. York*, in good black crystals at Willsboro', presenting interesting forms; also near the bridge at Potsdam, near Greenwood Furnace, and in Warwick, Orange Co.; dark green crystals near Two Ponds, and also 1 m. N., 2½ m. N., and 1 m. S., of Edenville, together with gray or hair-brown crystals and tremolite, titanite, and chondrodite, in granular limestone; of various forms and colors, and often in large and perfect crystals, near Amity; in dark green crystals, with ilmenite, at the Stirling mines, Orange Co.; in short green crystals at Gouverneur, St. Lawrence Co., sometimes 2 or 3 in. in diameter, along with apatite, also in fine long prisms of tremolite with brown tourmaline; with pyroxene at Russell in fine crystals; a black variety at Pierrepont; at Macomb, Pitcairn; tremolite at Fine; in Rossie, 2 m. N. of Oxbow, the variety pargasite in neat bright green crystals; glassy and radiated actinolite near a hamlet called Peeksville, in Fishkill; radiated at Brown's serpentine quarry, 3 m. N.W. of Carmel, Putnam Co; in large white crystals at Diana, Lewis Co.; radiated and bladed tremolite at Dover, Kingsbridge, the Eastchester quarries, Hastings, and near Yonkers, in Westchester Co.; at Knapp's quarry, Patterson, in Putnam Co., and on the banks of Yellow lake and elsewhere in St. Lawrence Co.; asbestus, near Greenwood Furnace; Rogers's farm in Patterson; Colton rock and Hustis's farm in Phillipstown, Putnam Co.; near the Quarantine in Richmond Co., in long fibers.

In *N. Jersey*, tremolite or gray amphibole in good crystals at Bryam, and other varieties of the species at Franklin and Newton, radiated actinolite, also a zinc-manganese variety (anal. 122) at Franklin Furnace, Sussex Co.; asbestus and mountain leather at Brunswick. In *Penn.*, actinolite in Providence, at Mineral Hill, in Delaware Co.; at Unionville; at Kennett, Chester Co., often in fine crystals; tremolite with asbestus at Chestnut Hill near the Wissahickon, near Philadelphia; at London Grove, Chester Co. In *Maryland*, actinolite and asbestus at the Bare Hills in serpentine; asbestus is mined at Pylesville, Harford Co.; amphibole-anthophyllite at Mt. Washington, 6 miles north of Baltimore. In *Virginia*, actinolite at Willis's Mt., in Buckingham Co.; asbestus at Barnet's Mills, Fauquier Co. Nephrite in Alaska as already noted.

---

* Also later Beck & Mushketov (Vh. Min. Ges., **18**, 1, 1883), who give a map of the known localities in the Kuen-Lun Mts., and a summary of the occurrence of nephrite in different parts of the world; besides describing with many analyses (quoted on p. 394) the Siberian occurrences.

† The size of this stone (in centimeters) is as follows: length 192 (= 6·3 ft.), breadth 36½ above and 34 below, height, 30 (B. & M.).

In Canada, tremolite is abundant in the Laurentian limestones, at Calumet Falls, Litchfield, Pontiac Co., Quebec; also at Blythfield, Renfrew Co., and Dalhousie, Lanark Co.; good crystals in limestone at Algona, Renfrew Co. Black hornblende at various localities in Quebec and Ontario with pyroxene, apatite, titanite, etc., as in Renfrew Co.; fine crystals of pargasite, also tremolite, on the Madawaska, Blythfield, Renfrew Co., Ontario. Black hornblende with the magnetite of Bathurst and South Sherbrooke, Lanark Co., Ontario. Asbestus and mountain cork at Buckingham, Ottawa Co., Quebec; a bed of actinolite at St. Francis, Beauce Co., Quebec; nephrite has been found in British Columbia and North-west Territory, as already noted.

**Alt.**—The alterations of amphibole are similar to those of pyroxene (see pp. 362, 363). The fibrous and diallage-like varieties are especially liable to take up water, owing to the finely or thinly divided state of the mineral. Talc, steatite, serpentine, chlorite, epidote, biotite, pinite, chabasite, limonite, magnetite, iron ocher, are among the reported results of alteration.

At Ilmenau, a magnesia-mica, a chlorite, and also (as an after-product from the chlorite) iron-ocher, occur as pseudomorphs after hornblende. *Groppite*, and perhaps *rosite* (4th Ed., p. 287), may be altered pargasite. Genth describes the asbestiform or fibrous serpentine of Texas and Providence, Pa., and the *baltimorite* as altered asbestus, and a chrysotile of Delaware Co., Pa., as altered actinolite (Am. J. Sc., 33, 203, 1862). The *hydrous anthophyllite* of New York Island occurs in place near the corner of 59th street and 10th avenue, and also in many places in boulders. The variations in the analyses, as well as in the aspect of the material, show that it is a result of the alteration of an asbestiform tremolite. Cf. p. 384.

Several alteration-products of amphibole are given below.

**Artif.**—Obtained artificially by Khrushchov, see p. 1026.

**Ref.**—[1] Finl. Min., 56, 1855, Min. Russl., 8, 159, 1878; cf. Rath, Pogg., Erg., **6**, 229, 1874, Arzruni, Ber. Ak. Berlin, March 30, 1882, Franzenau, Zs. Kr., 8, 568, 1884.

The position here taken is that adopted by Tschermak (Min., 442, 1884) and shown conclusively by G. H. Williams (Am. J. Sc., **39**, 352, 1890) to be the true one as exhibiting the relation to pyroxene; cf. 13, p. 387, where the crystals of the two species are in parallel position and the basal planes nearly coincide. It was early shown by Rath (l. c.) of Vesuvian amphibole that crystals occur parallel with augite, with $p$ of the one corresponding to $s/s'$ of the other.

To transform the formerly accepted symbols, $hkl$ (where $p = 001$, $r = \bar{1}11$, etc.), to those here taken ($pqr$), note that $p = -(h + l)$, $q = k$, $r = l$.

The following (Tschermak, Franzenau) show the variation in angle in some of the kinds of amphibole:

| | | Actinolite | Vesuvius | Brevik | Pargas | Aranyer Berg |
|---|---|---|---|---|---|---|
| $mm'''$ | = | 55° 32′ | 55° 31′ | 55° 41′ | 56° 0′ | 55° 43′ |
| $rr'$ | = | | 31° 29′ | | 31° 42′ | 31° 38′ |
| $mr'$ | = | | | 68° 46′ | | 68° 58′·3 |

[2] Cf. Mlr., 297, 1852; Dx., **1**, 77, 1862; Schrauf, Atlas, Tf. VII, VIII, 1864; Kk., l. c.; Gdt. Index, **1**, 190, 1886. [3] Franzenau, Aranyer Berg, l. c. [4] Cathrein, Fleimsthal, Zs. [8] *Composition* discussed, Scheerer, Pogg., **84**, 321 *et seq.*, 1851; Rg., Pogg., **103**, 273 *et seq.*, 1858; Tschermak, Min. Mitth., 38, 1871; Berwerth, Ber. Ak. Wien, **85** (1), 153, 1882; Scharizer, Jb. Min., **2**, 143, 1884. Relation between composition and optical characters, Wiik, Zs. Kr., **7**, 79, 1882.

The following are more or less altered amphiboles:

KIRWANITE *Thomson*, Min., **1**, 378, 1836. A fibrous, green, chlorite-like mineral from the basalt of the N. E. coast of Ireland. R. D. Thomson found in it: $SiO_2$ 40·50, $Al_2O_3$ 11·41, FeO 23·91, CaO 19·78, $H_2O$ 4·35 = 99·95. According to Lacroix it is an impure altered amphibole, Bull. Soc. Min., **8**, 429, 1885.

LOGANITE *T. S. Hunt*, Phil. Mag., **2**, 65, 1851, Rep. G. Canada, 491, 1863. Amphibole from Calumet Falls, Quebec, retaining its form and cleavage, but near penninite in composition. See 5th Ed., p. 242, p. 496.

PALIGORSKITE *T. v. Savchenkov*, Vh. Min. Ges., 102, 1862. Fibrous. Soft, but tough. G. = 2·217. Color white. Analysis: $SiO_2$ 52·18, $Al_2O_3$ 18·32, MgO 8·19, CaO 0·59, $H_2O$ 12·04, hygrosc. water 8·46 = 99·84. B.B. infusible. Not acted on by the acids.

From the Permian mining district of the Ural. Probably an altered asbestus.

PHĀACTINITE *Bertels*, Verh. Würzb. Ges., 8, in JB. Ch., 1267, 1874. An alteration product of amphibole, forming radiated masses, doubly refracting. H. = 2. G. = 2·997–3·057. Color dirty grayish brown. Analysis after deducting a little magnetite: $SiO_2$ 35·5, $Al_2O_3$ 16·9, $Fe_2O_3$ 25·4, MnO 1·4, MgO 5·3, CaO 7·2, $H_2O$ 8·1 = 99·8. From the rock called by the same author isenite, occurring in Nassau, Germany.

WALDHEIMITE. Amphibol-ähnliches Min. von Waldheim *A. Knop*, Lieb. Ann., **110**, 363, 1859; Waldheimit *Rg.*, Min. Ch., 780, 1860. An amphibole-like mineral from the serpentine of Waldheim, Saxony, which contains much *soda*, and is peculiar also in its excess of silica, both suggesting that it may be amphibole altered by the alkaline process. It occurs in veins an inch thick, and resembles actinolite. H. = 5; G. = 2·957; color leek-green; translucent. Analysis, Knop:

$SiO_2$ 58·71 $Al_2O_3$ 1·52 FeO 5·65 MnO 0·25 MgO 10·01 CaO 11·53 $Na_2O$ 12·38 = 100·05

**339. GLAUCOPHANE.** Glaukophan *Hausmann*, J. pr. Ch., 34, 238, 1845. Gastaldite *Strüver*, Mem. Acc. Linc., 2, 333, 1875.

Monoclinic; near amphibole in form. In thin prismatic crystals with *a*, *b*, *m*, and rarely *p* ($\bar{1}01$) and *r* (011). Measured angles, Bodewig:

$mm''' = 58° 16'$, $cr = 34° 12'$, $m'r = 67° 17'$, cf. Amphibole, p. 387.

Crystals prismatic in habit, usually indistinct; commonly massive, fibrous, or columnar to granular.

Cleavage: *m* perfect. Fracture conchoidal to uneven. Brittle. H. = 6–6·5. G. = 3·103–3·113 Hausm.; 3·044 Svr. Luster vitreous to pearly. Color azure-blue, lavender-blue, bluish black, grayish. Streak grayish blue. Translucent.

Pleochroism strongly marked: $\mathfrak{c}$ sky-blue to ultramarine-blue, $\mathfrak{b}$ reddish or bluish violet, $\mathfrak{a}$ yellowish green to colorless. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically +. Ax. pl. ‖ *b*. $\mathfrak{c} \wedge \dot{c} = 4°$ to 6°, rarely higher values: 11° to 12° Kotō. Bodewig gives for the extinction-angles with $\dot{c}$ on *b*: 4° 24′ Li, 4° 16′ Na, 4° 13′ Tl. Axial angles:

$2E_{a.r} = 84° 42'$ $2E_{a.y} = 85° 35'$ $2E_{a.gr} = 86° 39'$ $2H_{a.r} = 51° 3'$ $2H_{a.y} = 51° 11'$ $2H_{a.gr} = 51° 24'$

Also $\beta = 1·6442$ gastaldite, Sanger (Rosenbusch).

**Comp.**—Essentially $NaAl(SiO_3)_2.(Fe,Mg)SiO_3$. If Mg : Fe = 2 : 1, the formula requires: Silica 57·6, alumina 16·3, iron protoxide 7·7, magnesia 8·5, soda 9·9 = 100.

**Obs.**—Occurs as the hornblendic constituent of certain crystalline schists, called *glaucophane-schists*, or glaucophanyte; also more or less prominent in mica schists, amphibolytes, gneiss, eclogytes, etc. It is often associated with mica, garnet, diallage and omphacite, epidote and zoisite, etc.

First described from the island of Syra, one of the Cyclades; since shown to be widely distributed (cf. Oebbeke, Zs. G. Ges., **38**, 634, 1886, and Zs. Kr., **12**, 282, 1886). Occurs at Zermatt in Switzerland, on the north side of the Matterhorn, as also on the south side in the Val Tournanche; in the valley of Aosta, near Camp de Praz and St. Marcel, also at Brosso, near Ivrea, and in the Val Locana, Val d'Ala, Valle-Grande di Lanzo (*gastaldite*); at other points in the southern slope of the Alps, as well as in Switzerland; on the island of Corsica; Is. Groix, northwest coast of France; in the Fruška gora in Croatia. In New Caledonia with garnet and mica at the Balade mine. On the island of Shikoku, Japan.

In the U. S., glaucophane schists, closely resembling those of Syra, have been described from the Coast Ranges of California, as at Sulphur Bank, Lake Co., and at other points; the glaucophane is associated with zoisite and mica (Becker).

Glaucophane has been noted as a secondary product due to the alteration of diallage by a process of "glaucophanization:" the original diallage contained 2·23 p. c. $Na_2O$, Kotō, l. c.

Glaucophane is named from γλαυκος, *bluish green*, and φάινεσθαι, *to appear*. Gastaldite is named after Prof. Bartolomeo Gastaldi.

**340. RIEBECKITE** *A. Sauer*, Zs. G. Ges., **40**, 138, 1888. *Bonney*, Phil. Trans., **174**, 283, 1883.

Monoclinic. In embedded prismatic crystals, longitudinally striated.

Cleavage: prismatic (56°) perfect. Luster vitreous. Color black. Pleochroism very strongly marked: $\mathfrak{c}$ green, $\mathfrak{b}$ ($= \overset{|}{\bar{b}}$) deep blue, $\mathfrak{a}$ (nearly $\parallel c$) dark blue. Optically −. Extinction-angle small, $\mathfrak{a} \wedge \dot{c} = 4°–5°$ (±?). Axial angle large.

**Comp.**—Essentially $2Na\overset{III}{Fe}(SiO_3)_2.FeSiO_3$ = Silica 50·5, iron sesquioxide 26·9, iron protoxide 12·1, soda 10·5 = 100. It corresponds closely to acmite (ægirite) among the pyroxenes.

**Anal.**—1, Sauer, after deducting 7·12 p. c. zircon. 2, Id. 3, Koenig, Zs. Kr., **1**, 430, 1877 (also with slightly different numbers, Proc. Ac. Philad., 10, 1877).

[a] Incl. $Li_2O$.

Analysis 3 is referred here by Lcx. (see below) on the basis of an optical examination, but it differs in the state of oxidation of the iron, and approaches more nearly to crocidolite.

**Obs.**—Originally described from the granite and syenite of the island of Socotra in the Indian Ocean, 120 miles N. E. of Cape Guardafui, the eastern extremity of Africa. It occurs in groups of prismatic crystals, often radiating and closely resembling tourmaline.

A similar amphibole occurs at Mynydd Mawr, Carnarvonshire, Wales (Bonney, Min. Mag., 8, 103, 1888, ib. p. 169, 1889). Also another in granulyte in Corsica. Pleochroism: $\mathfrak{c}$ yellowish green, $\mathfrak{b}$ blue, $\mathfrak{a}$ indigo, nearly black. Axis $\mathfrak{a}$ inclined a few degrees to $\dot{c}$. Cf. Le Verrier, Lcx., C. R., **109**, 38, 39, 1889.

An "arfvedsonite" from St. Peter's Dome, Pike's Peak region, El Paso Co., Colorado, occurring with astrophyllite and zircon is shown by Lacroix (ibid.) to be near riebeckite. Extinction-angle on $b$, $\mathfrak{a} \wedge \dot{c} = 3°$ to $4°$.

**341. CROCIDOLITE.** Blau-Eisenstein (fr. S. Africa) *Klapr.*, Mag. Berl. Ges. N. Fr., **5**, 72, 1811, Beitr., **6**, 237, 1815. Krokydolith *Hausm.*, Gel. Anz. Gött., 1585, 1831. Blue Asbestus. Abriachanite *Heddle*, Min. Mag., **3**, 61, 193, 1879.

Fibrous, asbestus-like; fibers long but delicate, and easily separable. Also massive or earthy.

Cleavage: prismatic, 56°. H. = 4. G. = 3·20–3·30. Luster silky; dull. Color and streak lavender-blue or leek-green. Opaque. Fibers somewhat elastic. Pleochroism: $\mathfrak{c}$ green, $\mathfrak{b}$ violet, $\mathfrak{a}$ blne.

Optically +. Extinction-angle on $b$, inclined 18° to 20° with $\dot{c}$. 2E = 95° approx. Indices $\gamma - \alpha = 0·025$ Lcx.[1]

**Comp.**—Near riebeckite and perhaps only a fibrous variety. Formula $Na\overset{III}{Fe}(SiO_3)_2.FeSiO_3$ nearly = Silica 49·6, iron sesquioxide 22·0, iron protoxide 19·8, soda 8·6 = 100.

Magnesium and calcium replace part of the ferrous iron, and hydrogen part of the sodium. Chester's analysis gives: $2H_2O.Na_2O.3FeO.Fe_2O_3.9SiO_2$.

[a] Loss 0·95 p. c. at 100°.

**Pyr.**, etc.—In the closed tube yields on strong ignition a little water. B B. fuses easily with intumescence to a black magnetic glass, coloring the flame yellow (soda). With the fluxes gives reactions for iron. Unacted upon by acids.

**Obs.**—Occurs in South Africa, in Griqualand-West, north of the Orange river, in a range of quartzose schists called the Asbestos Mountains, which extends in a northeasterly direction from Griquastad toward Transvaal, 700 m. north of the Cape of Good Hope. In a micaceous porphyry at Wakembach, near Framont, in the Vosges. At Golling in Salzburg, in gypsum with blue quartz; at Ruka, near Domaschow in Moravia, with a ferruginous dolomite; in Greenland, both fibrous and earthy.

In the U. S., at Beacon Pole Hill, near Cumberland, R. I., in a granite ledge disseminated in fine particles in feldspar, also in as large as a butternut masses with radiated fibrous structure. Emerald Mine, Buckingham and Perkin's Mill, Templeton, Ottawa Co., Ontario, Canada (Lcx., Bull. Soc. Min., **13**, 10, 1880).

*Abriachanite* is an earthy amorphous form occurring in seams and cavities of the gneiss and granite of the Abriachan district, near Loch Ness, in Inverness-shire, Scotland.

A similar mineral from the zircon-syenite of Stavern, Norway, is referred here by Hausmann; this is the Faseriger Siderit *Leonh.*, Gebl. J., 3, 101, and Fasriges Eisenblau *Hausm.*, Handb., 1076, 1813. According to Brögger the Stavern mineral is a fibrous variety of the pyroxene, ægirite; he suggests further a like relation for the South African mineral; but cf. Lcx., l. c., and C. R., **109**, 39, 1889.

Crocidolite is named from *κροκίς*, *woof*, in allusion to its fibrous structure.

**Alt.**—The South African mineral is largely altered by both oxidation of the iron and infiltration of silica, resulting in a compact siliceous stone of delicate fibrous structure, chatoyant luster, and bright yellow to brown color, popularly called *tiger-eye* (also cat's-eye and Faserquarz, Tigerauge, Falkenauge (bluish var.) *Germ.*). Many varieties occur forming transitions from the original blue mineral to the final product; also varieties depending upon the extent to which the original mineral has penetrated the quartz. Cf. Renard and Klement, l. c. The softer (H. = 4) alteration product, consisting of silica with iron oxide, is made a ferric silicate by Hepburn, Ch. News, **55**, 240, 1887, and called *griqualandite* (cf. Brough., ib., **56**, 244, 1887).

Anal.—1, 2, Renard and Klement, l. c. 3, Rg., Min. Ch., Erg., 194, 1886. 4, 5, Wibel and Neelsen, Jb. Min., 367, 1873. 6, Hepburn, l. c.

**Ref.**—[1] Bull. Soc. Min., **13**, 10, 1890.

**342. ARFVEDSONITE.** *Brooke*, Ann. Phil., **5**, 381, 1823. Arfwedsonit. Soda-hornblende.

Monoclinic. Axes: $\breve{a} : \bar{b} : \dot{c} = 0·55687 : 1 : 0·29781$; $\beta = 73° 2\frac{1}{4}' = 001 \wedge 100$ Brögger[1].

$100 \wedge 110 = 28° 2\frac{1}{2}'$, $001 \wedge 101 = 23° 52\frac{1}{6}'$, $001 \wedge 011 = 15° 54'$.

**Forms:** *a* (100, *i*-ī), *b* (010, *i*-ĭ), *m* (110, *I*), *t* (101, 1-ī), *p* (1̄01, 1-ī), *r* (011, 1-ĭ), *i* (031, 3-ĭ), *k* (2̄11, 2-2), *z* (1̄21, 2-2̆).

Angles (cf. f. 14, p. 387): *mm'''* = *56° 5′, *at* = 49° 10′, *a′p* = *75° 44½′, *rr′* = 31° 48′, *br* = *74° 6′, *ii* = 81° 2′, *zz′* = 60° 0′, *pr* = 34° 40′, *pm* = 77° 27′.

Crystals long prisms, often tabular ∥ *b*, but seldom distinctly terminated: also in prismatic aggregates. Twins: tw. pl. *a*.

Cleavage: prismatic, perfect; *b*, less perfect. Fracture uneven. Brittle. H. = 6. G. = 3·44–3·45. Luster vitreous. Color pure black; in thin scales deep green. Streak deep bluish gray. Opaque except in thin splinters.

Pleochroism strongly marked: $\mathfrak{c}$ deep greenish blue, $\mathfrak{b}$ lavender, $\mathfrak{a}$ pale greenish yellow. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$; sections ∥ *a* are deep greenish blue, ∥ *b* olive-green. Optical character somewhat uncertain, probably (Bgr.) +, and $\mathfrak{c} = Bx_a$ (but cf. below and p. 383). Extinction-angle on *b*, with $\dot{c}$, = −14°.

**Comp.**—A slightly basic metasilicate of sodium, calcium, and ferrous iron chiefly; Lorenzen's analysis gives $4Na_2O.3CaO.14FeO.(Al,Fe)_2O_3.21SiO_2$.

**Anal.**—1, Lorenzen, Min. Mag., **5**, 50, 1882. 2, Berwerth, Ber. Ak. Wien, **85** (1), 168, 1882.

|  | G. |  | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |

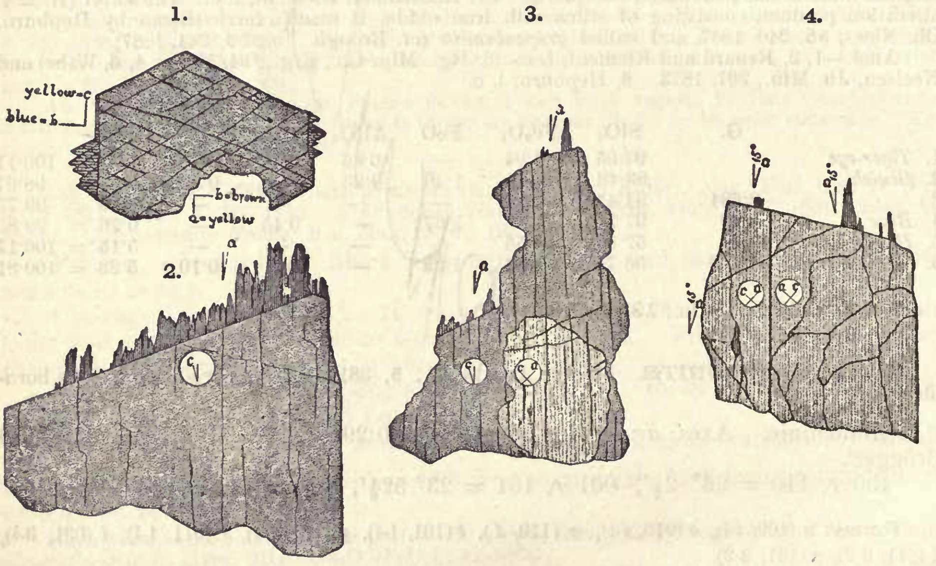
| 2. " | 3·454 | ⅔ | 47·08 | 1·44 | 1·70 | 35·65 | — | — | 2·32 | 7·14 | 2·88 | 2·08=100·29 |

The supposed arfvedsonite from Greenland analyzed by von Kobell, Rbg., etc., has been shown to be ægirite (see p. 365); that from Pike's Peak, Colorado, analyzed by Koenig is referred to riebeckite by Lacroix, C. R., **109**, 39, 1889.

**Pyr., etc.**—B.B. fuses at 2 with intumescence to a black magnetic globule; colors the flame yellow (soda); with the fluxes gives reactions for iron and manganese. Not acted upon by acids.

**Obs.**—Occurs in black hornblende-like crystals at Kangerdluarsuk in Greenland, with sodalite, eudialyte, and feldspar; also from Kumernit, near Tunugdliarfik, Siorarsuit; the Greenland crystals are sometimes 9 inches long; also very sparingly in the augite and elæolite-syenite of the Langesund fiord, southern Norway. More abundant in quartz-syenite and soda-granite between Mjösen and the Langesund fiord, near Christiania especially at the lake Sognsvand, at Gunilrud in the parish of Eker, and Kongsberg; at Rökeberg, Eker, occurs interlaminated with ægirite in parallel position.

A blue amphibole occurring as a pseudomorphic replacement and also as a secondary growth fringing crystals and grains of ordinary brown hornblende and others of pyroxene, seems to belong here, cf. Cross, Am. J. Sc., **39**, 359, 1890. Optical character probably negative. Ax. pl. ‖ $b$. Extinction-angle on $b$, or $\mathfrak{a} \wedge \dot{c} = -13°$ to $-15°$. Axial angle large. Pleochroism: $\mathfrak{c}$ pale yellow, $\mathfrak{b}$ purple to violet, $\mathfrak{a}$ deep blue. Absorption $\mathfrak{a} > \mathfrak{b} > \mathfrak{c}$. Occurs in a dike-rock cutting the Archæan gneisses at the northern base of the Rosita hills, 5 miles east of the mining town Silver Cliff, Custer Co., Colorado. Riebeckite and a secondary pyroxene near ægirite occur in the same rock.



Figs. 1, 2, A secondary blue amphibole (arfvedsonite ?) fringing, in parallel position, brown hornblende; 3, also enclosing pyroxene. 4, Pyroxene (twin, ‖ $a$) with similar secondary amphibole, also in twinning position. Cross.

**Alt.**—The following are analyses of altered arfvedsonite by Rördam, Zs. Kr., **16**, 406, 1890.

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ |  |
|---|---|---|---|---|---|---|---|---|
| 48·73 | 2·18 | 37·32 | — | 0·58 | 10·24 | 0·82 | 0·72 | = 100·59 |
| 52·12 | 2·33 | 32·33 | — | 0·62 | 10·95 | 0·88 | 0·77 | = 100 |
| 49·90 | 2·62 | 32·99 | 0·05 | 0·57 | 12·88 | 0·10 | 1·07 | = 100·18 |
| 49·50 | 2·75 | 32·86 | 0·06 | 0·60 | 13·01 | — | 1·53 | = 100·31 |

As shown by Steenstrup and Brögger, the change is one leading in the direction of the formation of an acmite (ægirite) free from calcium—in other words, a process the reverse of uralitization. Ferric hydrate and, again, magnetite occur with the acmite. Lepidomelane also occurs with the acmite as a result of the change, analogous to "pterolite" noted under barkevikite beyond.

**Ref.**—[1] Lille-Arö, Norway, Zs. Kr., **16**, 398, 1890.

342A. BARKEVIKITE *W. C. Brögger*, G. För. Förh., **9**, 269, 1887; Zs. Kr., **16**, 412, 1890. Barkevicite.

An amphibole near arfvedsonite. In short or long prismatic crystals, sometimes very large and rough; showing the forms: *b* (010), *r* (011), *p* ($\bar{1}01$), *k* ($\bar{2}11$), *z* ($\bar{1}21$). Cleavage: prismatic, perfect, yielding an angle of 55° 44½′; *b* also rather perfect. Fracture uneven. Brittle. G. = 3·428 Rg. Luster vitreous. Color deep velvet-black. Pleochroism marked: deep brown and light brown-yellow for the axes ∥ *b*, the former for the axis inclined + 12½° to $\acute{c}$; brownish red for the axis $\mathfrak{b}$, normal to *b*. Extinction-angle with $\acute{c}$ on *b* = + 12½°.

Composition near arfvedsonite, but more basic; the ratio of $SiO_2 : (Al,Fe)_2O_3 : (Fe,Mn,Ca,Mg)O : (Na,K)_2O = 0·707 : 0·148 : 0·498 : 0·113$ for Flink's analysis (calc., Bgr.). Analyses 1, 2 are referred here by Brögger, while other amphiboles from Fredriksvärn analyzed by Rg. (l. c.) are shown to be intermediate between barkevikite and ordinary hornblende.

1, Plantamour, Bibl. Univ., **6**, 337, 1841. 2, Rg., Pogg., **103**, 447, 1858. 3, Flink, Zs. Kr., **16**, 412, 1890.

[a] Incl. $TiO_2$.

B B. fuses easily, but somewhat less so than arfvedsonite.

Occurs at the wöhlerite locality, Skudesundsskjär near Barkevik (or Barkevig) on the Langesund fiord; also as an essential constituent of the augite-syenite of southern Norway, in the region between the Christiania and Langesund fiords. Sometimes occurs in parallel intergrowth with arfvedsonite, and again with a green hornblende.

PTEROLITE *Breithaupt*, B. H. Ztg., **24**, 336, 1865. Described as a member of the mica group, from the Brevik region, Norway, occurring in scales of an olive-green to liver-brown color grouped in fan-shaped forms (hence named from *πτερόν, feather*). Analyzed by Müller (l. c.). Shown by Lacroix to be a heterogeneous substance (Bull. Soc. Min., **10**, 145, 1887), and later by Brögger (Zs. Kr., **16**, 418, 1890) to be an alteration-product of the amphibole, barkevikite, the soluble portion being lepidomelane and the insoluble ægirite. Anal., Müller:

## γ. *Triclinic Section.*

**343. ÆNIGMATITE.** Ainigmatit *Breith.*, B. H. Ztg., **24**, 398, 1865. Kölbingit *Id.*, ibid. *Lorenzen*, Min. Mag., **5**, 55, 1882. Cossyrit *Förstner*, Zs. Kr., **5**, 348, 1881.

Triclinic. In crystals approximating closely in angle, habit, and occurring forms to ordinary amphibole, but having a prismatic angle of 66°. Axes[1] (approx.) $\breve{a} : \bar{b} : \acute{c} = 0·6778 : 1 : 0·3506$; $\alpha = 90°$, $\beta = 72° 49'$, $\gamma = 90°$.

**Forms,** *Ænigmatite:*
*a* (100, *i*-ī)
*b* (010, *i*-ĭ)
*m* (110, *I*′)
*e* (130, *i*-3̆′)
*M* ($1\bar{1}0$, ′*I*)
*ϵ* ($1\bar{3}0$, ′*i*-3̆)
*p* ($\bar{1}01$, ,1-ī,)?
*r* (011, 1-ĭ′)
*j* (031, 3-ĭ′)
*ρ* (051, 5-ĭ′)
*R* ($0\bar{1}1$, ′1-ĭ)
*i* ($0\bar{3}1$, ′3-ĭ)
*ξ* ($0\bar{5}1$, ′5-ĭ)
*z* ($\bar{1}21$, ,2-2̆)
*φ* ($\bar{4}\bar{3}3$, $\frac{4}{3}$-$\frac{4}{3}$,)
*ζ* ($\bar{1}\bar{2}1$, 2-2̆,)

Measured angles: $mM = 66° 31'$ Breith.; also, Bgr., $mM = 66° 4'$ to $66° 11'$, $bm = 56° 44'$ to 45′, $b\rho = 29° 38\frac{1}{2}'$, $Mz = 62° 23\frac{1}{2}'$, $m\rho = 53° 12'$, $M\rho = 68° 34'$.

*Cossyrite:*
*a* (100, *i*-ī)
*b* (010, *i*-ĭ)
*m* (110, *I*′)
*e* (130, *i*-3̆′)
*M* ($1\bar{1}0$, ′*I*)
*ϵ* ($1\bar{3}0$, ′*i*-3̆)
*p* ($\bar{1}01$, ,1-ī,)
*r* (011, 1-ĭ′)
*ρ* (051, 5-ĭ′)
*i* ($0\bar{3}1$, ′3-ĭ)
*d* ($0\bar{7}1$, ′7-ĭ)
*x* (213, $\frac{2}{3}$-2′)
*u* (233, 1-$\frac{3}{2}$′)
*f* ($\bar{4}33$, ,$\frac{4}{3}$-$\frac{4}{3}$)
*v* ($\bar{2}31$, ,3-$\frac{3}{2}$)
*z* ($\bar{1}21$, ,2-2̆)
*k* ($\bar{2}\bar{1}1$, 2-2̄,)
*ζ* ($\bar{1}\bar{2}1$, 2-2̆,)
*σ* ($\bar{2}\bar{5}1$, 5-$\frac{5}{2}$,)
*q* ($2\bar{1}1$, ′2-2̄)

The following are angles for cossyrite (Förstner) compared with the corresponding angles for amphibole:

| | Cossyrite | Amphibole | | Cossyrite | Amphibole |
|---|---|---|---|---|---|
| $mM =$ | 65° 51′ | 55° 49′ | $b\rho =$ | 29° 27′ | 35° 19′ |
| $bm =$ | 56° 38′ | 62° 5½′ | $bi =$ | 44° 50′ | 49° 44′ |
| $ab =$ | 90° 6′ | 90° 9′ | $bk =$ | 74° 6′ | 77° 13′ |
| $a'p =$ | 77° 47′ | 75° 2′ | $mk =$ | 50° 36′ | 49° 24′ |
| $br =$ | 71° 29′ | 74° 14′ | $pk =$ | 29° 23′ | 27° 25′ |

Crystals prismatic in habit. Twins common with tw. pl. $b$, contact-twins; also with enclosed tw. lamellæ, giving striations on the terminal planes and on $a$.

Cleavage: prismatic, distinct. Fracture uneven. Brittle. G. = 3·85 Breith., 3·80 Lorenzen, for ænigmatite; 3·74–3·75 Förstner, for cossyrite. Luster vitreous. Color black. Streak reddish brown. Translucent to opaque.

Pleochroism strongly marked, especially for sections ∥ $b$; for those ∥ $a$ less so. $\mathfrak{c}$ brown-black, $\mathfrak{b}$ deep chestnut-brown, $\mathfrak{a}$ clear red-brown. Absorption strong, $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically +. Ax. pl. nearly ∥ $b$. Extinction-angle with $\acute{c}$ on $a = 3°\ 46'$, on $b = 44°\ 57'$. Bx $\wedge\ \acute{c} = +\ 45°$ approx. Ax. angle rather small, 2E = 60° approx. Bgr.

**Var.**—1. *Ænigmatite* occurs in prismatic crystals, sometimes several inches in length. H. = 5·55. G. = 3·833–3·863 Breith., 3·80 Lorenzen. Color black. Streak reddish brown. Optical characters as given above. Breithaupt regarded the ænigmatite as pseudomorphous after kölbingite, which latter was distinguished by a pistachio-green streak and low specific gravity, viz. 3·60–3·61. The form of the two he made the same. Lorenzen, however, shows that the ænigmatite crystals cannot be pseudomorphs, while Brögger suggests that "kölbingite" may be only a parallel intergrowth of arfvedsonite and ænigmatite, such as he has observed.

2. *Cossyrite* occurs in minute embedded crystals. G. = 3·74–3·75. Color black. Extinction-angle with $\acute{c}$ on $a = 3°$, on $b = 39°$ approx.

**Comp.**—Essentially a titano-silicate of ferrous iron and sodium, but containing also aluminium and ferric iron, and slightly more basic than a normal metasilicate.

Forsberg's analysis for ænigmatite gives nearly $2Na_2O.9FeO.AlFeO_3.12(Si,Ti)O_2$.

Förstner's analysis for cossyrite approximates to $2Na_2O.10FeO.Al_2O_3.Fe_2O_3.15SiO_2$. As has been suggested, it is not improbable that cossyrite, like ænigmatite, contains titanium, replacing part of the silicon.

**Anal.**—1, Forsberg, quoted by Bgr. 2, Förstner, l. c.

| | $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $Na_2O$ | $K_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. *Ænigmatite* | 37·92 | 7·57 | 3·23 | 5·81 | 35·88 | 1·00 | 0·33 | 1·36 | 6·58 | 0·51 | = 100·19 |
| 2. *Cossyrite* | 43·55[a] | — | 4·96 | 7·97 | 32·87 | 2·37[b] | 0·86 | 2·01 | 5·29 | 0·33 | = 100·21 |

[a] Incl. $TiO_2$?. [b] Incl. 0·39 CuO.

**Pyr., etc.**—B.B. fuses easily to a brownish black glass. Partially decomposed by acids.

**Obs.**—*Ænigmatite* (and kölbingite) occurs in sodalite-syenite at Naujakasik near Tunugdliarfik, also at Kangerdluarsuk, Greenland; the first crystals were collected by Giesecke about 1810. Probably also in the Langesund fiord region of southern Norway, but not positively identified; Breithaupt is quoted (Bgr.) as mentioning the occurrence of a mineral resembling kölbingite with a prismatic angle of 66° to 67° from "Brevik." Probably in the elæolite-syenite of the peninsula Kola, Russian Lapland (Ramsay). Ænigmatite is named from αἴνιγμα, an *enigma*.

*Cossyrite* occurs in minute crystals embedded in the liparyte lavas of the island Pantellaria (whose ancient name was Cossyra). The crystals examined were weathered out of the groundmass.

**Ref.**—[1] Calculated from Förstner's angles: $110 \wedge 1\bar{1}0 = 65°\ 51'$; $br = 71°\ 29'$, $ar = 73°\ 44'$. Förstner calculates the following axial ratio and angles (referred to the usual amphibole position, where $r = \bar{1}\bar{1}1$, etc., see p. 398):

$$\breve{a} : \bar{b} : \acute{c} = 0·6627 : 1 : 0·3505; \quad \alpha = 90°\ 6', \quad \beta = 89°\ 54', \quad \gamma = 102°\ 13'.$$

Inasmuch, however, as the fundamental angles are the means of measurements varying widely, in one case more than 2°, the results can only be regarded as approximations. The table of calculated angles contains bewildering errors, *e. g.*: $010 \wedge 110 = 56°\ 38'$, $110 \wedge 1\bar{1}0 = 65°\ 51'$, $1\bar{1}0 \wedge 010 = 57°\ 6'$, which together equal 179° 35′ instead of 180°; again, $100 \wedge 110 = 33°\ 3'$, $110 \wedge 130 = 30°\ 21'$, $130 \wedge 010 = 26°\ 17'$, that is 89° 41′; while $100 \wedge 010 = 90°\ 6'$; etc.

The triclinic form of kölbingite (and ænigmatite), partly made out by Breithaupt, was established by Brögger, who also shows that there can be no doubt as to the identity of ænigmatite and the triclinic cossyrite.

## 4. Beryl Group. Hexagonal.

**344. Beryl** $Be_3Al_2(SiO_3)_6$ Hexagonal $\dot{c}$ 0·4989

**344. BERYL.** Σμάραγδος pt. [rest Chrysocolla, Malachite, etc., and other green stones] *Theophr.* Βήρυλλος *Gr.* Smaragdus pt. [rest as above] + Beryllus (Chrysoberyllus, Chrysoprasius, incl.) *Plin.*, **37**, 16–20. Emerald; Beryl; Aquamarine. Smaragdus + Beryll *Wall.*, Min., 117, 122, 1747. Crystals usually long prismatic, often striated vertically, rarely transversely; distinct terminations exceptional. Rarely tabular in habit[9]. Occasionally in large masses, coarse columnar or granular to compact.

Cleavage: ĉ imperfect and indistinct. Fracture conchoidal to uneven. Brittle. H. = 7·5–8. G. = 2·63–2·80; usually 2·69–2·70. Luster vitreous, sometimes resinous. Color emerald-green, pale green, passing into light blue, yellow and white; also pale rose-red. Streak white. Transparent to subtranslucent. Dichroism more or less distinct. Optically –. Double refraction feeble. Often abnormally biaxial[11]. Refractive indices, for green rays, Dx.[13]:

9–11, Alexander Co., N. C., basal projections; 9, 11, Washington.

*Emerald*, Muso $\omega = 1{\cdot}5841$ Elba $\omega = 1{\cdot}5771$ *Aquamarine*, Siberia $\omega = 1{\cdot}5820$
" " $\epsilon = 1{\cdot}5780$ " $\epsilon = 1{\cdot}5720$ " " $\epsilon = 1{\cdot}5765$

Also, Dufet[13]:

$\omega_r = 1{\cdot}58620$ Li $\omega_y = 1{\cdot}58935$ Na $\omega_{gr} = 1{\cdot}59210$ Tl
$\epsilon_r = 1{\cdot}57910$ Li $\epsilon_y = 1{\cdot}58211$ Na $\epsilon_{gr} = 1{\cdot}58485$ Tl

**Var.**—1. *Emerald.* Color bright emerald-green, due to the presence of a little chromium; it is highly prized as a gem when clear and free from flaws. The gem emeralds are locally known in South America as *canutillos;* the coarse, ill-formed or nodular emeralds are called morallons, see anal. 2 (Bouissingault).

The color was attributed to chromium by Vauquelin, but this was questioned by Lewy (see below). Wöhler, however, found in a Muso emerald 0·186 p. c. $Cr_2O_3$; it lost 1·62 p. c. upon ignition, but retained its color, Pogg., **122**. 492, 1864. This has been confirmed by later observers, Hofmeister, Rose, Williams. The last named (Proc. Roy. Soc., **21**. 409, 1873) finds carbon present as such, but the color is not lost by heating though the specific gravity falls by fusion from 2·69 to 2·40 and the fused mass can be scratched by quartz.

2. *Ordinary; Beryl.* Generally in hexagonal prisms. often coarse and large; green the common color. The following are determinations of the specific gravity given by Koksharov for Uralian beryls: colorless, transparent 2·694, 2 695; yellowish 2·681–2·694; green 2·702, 2·710; rose-red 2·725. Also 2·65, 2·66 for an Irish beryl, Williams, but after fusion 2·41. The cæsium beryl from Hebron, Me. (anal. 10), has G. = 2·79–2·81; it is perfectly transparent with a pale greenish tinge.

The principal kinds are: (*a*) colorless; (*b*) bluish green, called *aquamarine*, a name suggested, though not used, by Pliny, where he says of it, "qui viriditatem puri maris imitantur;" (*c*) apple-green; (*d*) greenish yellow to iron-yellow and honey-yellow (apparently *chrysoberyllus* of Pliny and ancient jewelry); sometimes a clear bright yellow as in the *golden beryl;* (*e*) pale yellowish green (probably the *chrysoprasius* Plin., and perhaps his *chrysolithus* in part, as also in more modern times); (*f*) clear sapphire-blue (*hyacinthozontes* of Plin.); (*g*) pale sky-blue (*aeroides* Plin.); (*h*) the pale violet or reddish (*améthiste basaltine* Sage, Min., 231); (*i*) the opaque brownish yellow, of waxy or greasy luster.

The *oriental emerald* of jewelry is emerald-colored sapphire. *Davidsonite* is greenish yellow beryl from near Aberdeen; it was supposed to contain "donium," Rec. Gen. Sc., 3, 426, 1836. *Goshenite* is a colorless or white variety of beryl from Goshen, Mass.

The union of emerald and beryl in one species, which Pliny says was suggested in his time, was first recognized on crystallographic grounds by De Lisle, and more satisfactorily through measurements of angles by Haüy; and chemically by Vauquelin.

**Comp.**—$Be_3Al_2Si_6O_{18}$ or $3BeO.Al_2O_3.6SiO_2$ = Silica 67·0, alumina 19·0, glucina 14·0 = 100.

As shown by Penfield alkalies ($Na_2O$, $Li_2O$, $Cs_2O$) are sometimes present replacing the beryllium, from 0·25 to 5 p. c.; also chemically combined water, including which the formula becomes $H_2Be_6Al_4Si_{12}O_{37}$. The Hebron beryl (anal. 10) is remarkable as containing 3·6 p.c. of cæsium oxide.

**Anal.**—1, Lewy, Ann. Ch. Phys., **53**, 5, 1858. 2, Boussingault, C. R., **69**, 1249, 1869. 3, Brax, Zs. Kr., **7**, 80, 1882. 4, Rg., Min. Ch., 650, 1875. 5, Spezia, Att. Acc. | Ign. | 2·33 | 2·44 | 2·69 | 2·19 | 2·04 | 2·08 | 1·14 |

Also Habachthal, Tyrol, 2·26 $Na_2O$; Bodenmais 1·20 $Na_2O$; Limoges 0·73 $Na_2O$; further some $Li_2O$ in all. In a beryl from Elba, with G. = 2·70–2·71, Bechi found 0·88 $Cs_2O$, Boll. Com. Geol., 1, 83, 1870.

An anomalous composition to a beryl from Glencullen, Ireland, is given by Hartley, but the analysis calls for confirmation. Proc. R. Dublin Soc., 5, 627, 1887.

Rosterite *Grattarola*, l. c. A slightly altered variety of beryl from Elba, named after Dr. G. Roster. It occurs in short prismatic to tabular doubly-terminated crystals. In polarized light a basal section is divided into six sectors, corresponding to the prismatic edges, for the three alternate of which the extinction is the same. Optically biaxial. Color pale rose-red. Anal. 1–4, Grattarola; 1, 2, from the ends of a crystal, which had a nucleus of normal beryl (anal. 3); 4, "typical rosterite."

**Pyr., etc.**—B.B. alone, unchanged or, if clear, become milky white and clouded; at a high temperature the edges are rounded, and ultimately a vesicular scoria is formed. Fusibility = 5·5 (Kobell), but somewhat lower for beryls rich in alkalies. Glass with borax, clear and colorless for beryl, a fine green for emerald. A yellowish variety from Broddbo and Finbo yields with soda traces of tin. Unacted upon by acids.

According to Lewy, the emerald of Muso becomes white at a red heat, and loses, as a mean result, 1·66 of water and 0·12 of organic matter, the latter consisting of 0·03 to 0·05 of hydrogen and 0·09 to 0·06 of carbon. Wöhler and Williams, however, as noted above, confirm the loss upon ignition (cf. Pfd.), but find the color retained.

**Obs.**—Beryl is a common accessory mineral in granite veins, in all parts of the world, especially in those of a pegmatitic character. Emeralds occur in clay slate, in isolated crystals or in nests, near Muso, etc., 75 m. N.N.E. of Bogota, United States of Colombia; the rock contains Cretaceous fossils in its limestone concretions. Emeralds of less beauty, but much larger, occur in Siberia, on the river Tokovoya, N. of Ekaterinburg, with phenacite, chrysoberyl, apatite, rutile, etc., embedded in mica schist. Also at Paavo, near Orijärvi, Finland. Mount Zalora, in Upper Egypt, affords a less distinct variety, and was the only locality which was known to the ancients. Occurs in the Heubachthal in Salzburg, in mica schist.

Emeralds of large size, though not of uniform color or free from flaws, have been obtained in Alexander Co., N. C., in pockets in gneiss, associated with hiddenite (spodumene), rutile, muscovite, etc. One crystal had a length of 9 inches; another was 3 in. long by 1¾ across and weighed 9 oz.

Transparent beryls are found in Siberia, India, and Brazil. In Siberia they occur at the emerald mine mentioned, at Mursinka and Shaitanka, near Ekaterinburg; near Miask with topaz; in the mountains of Adun-Chalon with topaz, in E. Siberia; in British India in the Coimbatore district and in the Punjab Himalayas; in Brazil on Rio San Mateo. Some Siberian transparent crystals exceed a foot in length. The most splendid aquamarine of which we have any account is from Brazil; it approaches in size, and also in form, the head of a calf, and exhibits a crystalline structure only on one side; the rest is water-worn; and it weighs 225 oz. troy, or more than 18½ lbs.; the specimen is transparent and without a flaw. Beautiful crystals also occur at Elba; at Lonedo in north-eastern Italy, with corundum, zircon, topaz, spinel; the tin mines of Ehrenfriedersdorf in Saxony, and of Schlackenwald in Bohemia.

Other localities are, the Mourne Mts., Ireland, Co. of Down; also Killiney near Dublin; yellowish green at Rubislaw, near Aberdeen, Scotland (davidsonite), and elsewhere in Aberdeenshire; in small bluish crystals at St. Michael's Mount in Cornwall; Limoges in France; Finbo and Broddbo in Sweden; Tamela and Somero in Finland; Fossum in Norway; Pfitsch-Joch, Tyrol; Bodenmais and Rabenstein in Bavaria; in New South Wales at various localities.

In the United States, beryls of gigantic dimensions have been found in *N. Hamp.*, at Acworth and Grafton, and in *Mass.*, at Royalston; but they are mostly poor in quality. One beryl from Grafton weighs 2,900 lbs.; it is 32 in. through in one direction and 22 in another transverse, and is 4 ft. 3 in. long. Another crystal from this locality, according to Prof. Hubbard, measures 45 in. by 24 in its diameters, and a single foot in length by calculation weighs 1,076 lbs., making it in all nearly 2½ tons. At Royalston, one crystal exceeded a foot in length; the smaller crystals are often limpid, and a yellowish variety forms a gem resembling chrysolite; the colors are mostly aquamarine, grass-green, and yellowish green; one locality is in the south-east part of Royalston, near the school-house, on the land of Mr. Clarke; the best crystals are embedded in quartz; a still better is situated 4 m. beyond the old one in South Royalston; some crystals of a sky-blue color in white quartz are beautiful.

Other localities are in *Maine*, at Albany; Norway; Bethel; at Hebron, a cæsium beryl (anal. 10) associated with pollucite; in Paris, with black tourmaline; at Bowdoinham and Topsham, pale green or yellowish; at Georgetown, Parker's island, mouth of Kennebec. In *N. Hamp.*, at Wilmot; at Compton, as good as at Royalston. In *Mass.*, at Barre, excellent specimens; at Pearl Hill in Fitchburg; at Goshen (goshenite), and at Chesterfield. In *Conn.*, at Haddam, in a feldspar vein in gneiss, on the east side of the river, the crystals having the terminations for a twelfth of an inch transparent; also at the chrysoberyl locality; at the Middletown and Portland feldspar quarries; in Chatham, in granite; at Monroe, in a granite vein, the crystals often consisting of displaced pieces separated by quartz; at Madison, in beautiful crystals; at New Milford, of a clear golden yellow to dark amber color, also fine green; a clear glassy kind in Willimantic, Conn.[12]; in large columnar masses at Branchville. In *Penn.*, at Leiperville and Chester, crystals sometimes 10 to 12 in. long and 1½ in diameter, with black tourmaline; at Mineral Hill. In *Virginia*, at Amelia Court House, sometimes pure white. In *N. Carolina*, in Alexander Co., near Stony Point, fine emeralds (see above), also clear green crystals, sometimes very highly modified; in Mitchell Co.; Morganton, Burke Co., and elsewhere. In *Alabama*, Coosa Co., of a light yellow color. In *Colorado*, near the summit of Mt. Antero, beautiful aquamarines with phenacite, bertrandite, etc., often corroded leaving steep pyramidal forms in the cavities (f. 8), the crystals having been the source of the beryllium in the associated secondary minerals. In *S. Dakota*, in the Black Hills in large crystals.

**Alt.**—Kaolin, mica, limonite, and quartz occur as pseudomorphs after beryl, the last two by substitution, the others by alteration. Analyses of altered beryls; 1, Müller, J. pr. Ch., **58**, 182, 1853. 2, Damour, Bull. G. Fr., **7**, 224, 1850. Anal. 2 corresponds nearly to kaolin.

PSEUDOSMARAGD *Atterberg*, G. För. Förh., 2, 405, 1874. Pseudo-emerald. A mineral resulting from the alteration of beryl. The name was introduced by Berzelius for pseudomorphous crystals, consisting, as he regarded it, of ordinary beryl and mica. Atterberg retains the name for the hard portion of similar pseudomorphs, which, however, he finds to be not true beryl. Its characters are: Hardness 5·5; G. = 2·70; luster waxy; color dark grayish green; fracture splintery. Intimately mixed with mica scales. Analyses: 1, 2; the latter on material not entirely free from mica:

| | $SiO_2$ | $Al_2O_3$ | BeO | FeO | MgO | $K_2O$ | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 57·32 | 17·46 | 13·11 | 0·30 | 0·32 | 7·82 | 3·64 | = | 99·97 |
| 2. | 56·23 | 19·05 | 12·55 | 0·18 | 0·50 | 7·45 | 4·83 | = | 100·79 |

The mineral differs from ordinary beryl in having lost part of its silica and gained potash and water; the alumina and glucina are sensibly unchanged. From Kårarfvet, near Falun, Sweden.

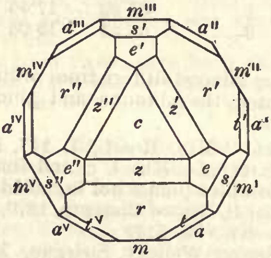
5.



Figs. 1, *Eudialyte*, 2, *Eucolite*, Magnet Cove, Ark., J. F. Williams. 3, 4, Greenland; 4, Lang. 5, Id., Mlr.

Crystals often tabular ‖ *c*, or rhombohedral in habit and highly modified (eudialyte); also prismatic, *a*, with *r* large or small (eucolite). Also massive in embedded grains; sometimes reniform.

Cleavage: in eudialyte, *c* perfect; *a* and *z* ($10\bar{1}4$) difficult, Dx.; in eucolite, *c* most distinct; also *a* and *m* imperfect, Bgr. Fracture subconchoidal, splintery. Brittle. H. = 5–5·5. G. = 2·91–2·93 eudialyte; 3·0–3·1 eucolite. Luster vitreous. Color rose-red, bluish red, brownish red, chestnut-brown. Streak uncolored. Translucent to subtranslucent.

Eudialyte is optically positive; eucolite is negative. Double refraction strong. Indices:

*Eucolite* $\omega = 1{\cdot}6205$ $\epsilon = 1{\cdot}6178$ Brögger.

**Var.**—Eudialyte and eucolite differ in optical character, the former +, the latter −, as stated above. Ramsay notes that both + and − zones, as also others which are isotropic, occur in the same crystal of the Kola eudialyte. The crystals of eudialyte are ordinarily more complex, and its specific gravity is sensibly lower. In composition a distinction can hardly be made.

Williams gives for Magnet Cove eudialyte, G. = 2·804–2·833; for eucolite 2·624–2·663. The eucolite is softer and probably somewhat altered; a derivation from eudialyte is suggested.

**Comp.**—Formula uncertain because the zirconium may be taken with either base or acid; the part played by the chlorine is also doubtful. Most simply regarded (Bgr.) as essentially a metasilicate, $\overset{I}{R}_4\overset{II}{R}_3Zr(SiO_3)_7$, with $\overset{I}{R} = Na$ chiefly, also K, H; $\overset{II}{R} = Ca$ chiefly, also Fe, Mn, and Ce(OH); further with $ZrOCl_2$ in part replacing the $SiO_2$; niobium (tantalum) may be present in small amount.

Rammelsberg, who has contributed most to our knowledge of the composition, regards the chlorine present as NaCl, and the zirconium as replacing silicon. For anals. 5–9 and 15, 16, he writes $2\overset{I}{R}_6\overset{II}{R}_3(Si,Zr)_{10}O_{26} + NaCl$; for 17–21, $R_{12}R_9(Si,Zr)_{25}O_{55}$. If Zr is to be taken as base he suggests $3(\overset{I}{R}_8\overset{II}{R}_6Zr_2Si_{13}O_{39}) + 2NaCl$. Groth regards it as probably a salt of $H_2Si_2O_5$.

[a] Incl. $La_2O_3$ 1·11 p. c. [b] Incl. $Y_2O_3$ 0·32 p. c.

**Pyr., etc.**—In the closed tube affords water. B.B. fuses at 2·5 to a light green opaque glass, coloring the flame yellow (soda). With the fluxes gives reactions for iron and manganese. With hydrochloric acid gelatinizes, and the dilute acid solution imparts a deep orange to turmeric paper even after the iron in solution has been reduced to colorless protochloride by boiling with metallic tin (reaction for zirconia).

**Obs.**—*Eudialyte* is found at Kangerdluarsuk, West Greenland, where it was discovered by Giesecke early in the century. It is associated with arfvedsonite and sodalite, or embedded in compact white feldspar; the crystals are usually small, but sometimes an inch or more in length; also on the island Sedlovaty in the White Sea in massive form, embedded in sodalite; at Lujavr on the Kola peninsula, Russian Lapland, in elæolite-syenite (Ramsay).

*Eucolite* is from islands of the Langesund fiord in Norway; it is common on the Arö islands. Eikaholmen; also in dikes in the ledges off Barkevik; on Låven and Stokö rare. It is associated with ægirite, catapleiite, astrophyllite, sodalite, leucophanite, also wöhlerite, fluorite.

Eudialyte and eucolite also occur at Magnet Cove, in Arkansas, of a rich crimson to peach-blossom-red color, in feldspar, with elæolite and ægirite (first noted by Shepard); probably also in the elæolite syenite of Saline Co., Ark., seven miles N.E. of Benton (Williams).

Eudialyte is named from εὔ, *easily*, and διαλύειν, *to dissolve*, alluding to its easy solubility in acids. Eucolite from εὔκολος has much the same meaning.

**Ref.**—[1] Mlr., Phil. Mag., **16**, 477, 1840; Min., 357, 1852. Other values are, for eudialyte $\dot{c}$ = 2·11159 Kk., Vh. Min. Ges., **14**, 205, 1879, and Min. Russl., **8**, 29; for eucolite $\dot{c}$ = 2·0966 Bgr. (but it should be 2·0895 from *ar* = *36° 52′); eudialyte, $\dot{c}$ = 2·1174 Magnet Cove, Williams, Am. J. Sc., **40**, 457, 1890.

[2] Cf. Mlr., l. c. Also Lang. Phil. Mag., **25**, 436, 1863; Dx., **1**, 160, 1862; Nd., Öfv. Ak. Stockh., **27**, 559, 1870; Kk., l. c.; Gdt., Index, **1**, 519, 1886. [3] Williams, l. c.

A mineral probably identical with eudialyte, but not investigated chemically, is described by Ussing (G. För. Förh., **10**, 190, 1888), from Kangerdluarsuk, Greenland. It occurs in rhombohedral crystals, with *c* prominent, also *e*. Observed forms: *c* (0001), *m* $(10\bar{1}0)$, *a* $(11\bar{2}0)$, *x* $(10\bar{1}6)$, *z* $(10\bar{1}4)$, *r* $(10\bar{1}1)$, *e* $(01\bar{1}2)$, *s* $(02\bar{2}1)$. Measured angles: *cx* = 22° 37′, *cz* = 31° 37′. *cr* = 67° 56′, *ce* = 51° 10′. H. = 5. G. = 2·970. Color yellow-brown. Transparent. Optically +.

Brögger also notes a mineral associated with the rosenbuschite of Norway in orange-colored crystals showing the forms *a*, *z*, *r*, *e*, also *ω* (4·1·5·25, $\frac{3}{2}\frac{5}{5}\frac{5}{3}$), but in part developed with monoclinic symmetry. He refers it provisionally to eucolite.

**346. CATAPLEIITE.** Katapleiit *Weibye & Sjögren*, Pogg., **79**, 300, 1850. Katapleït. Kalknatronkatapleït. Natronkatapleït *Brögger*, G. För. Förh., **7**, 427, 1884, Zs. Kr., **16**, 434, 1890.

Hexagonal at 140° C.; pseudo-hexagonal and monoclinic at ordinary temperatures Brögger[1].

If hexagonal, axis $\grave{c}$ = 1·3629; 0001 ∧ 1011 = *57° 34′ Hj. Sjögren[1].

Common forms: *c* (0001, *O*); *m* $(10\bar{1}0$, *I*); *o* $(10\bar{1}2$, ½), *p* $(10\bar{1}1$, 1), *x* $(20\bar{2}1$, 2). Angles: *co* = 38° 12′, *cp* = 57° 34′, *cx* = 72° 22½′, *oo′* = 36° 1′, *pp′* = 49° 55½′, *xx′* = 56° 55′.

Dauber[1] gave $\grave{c}$ = 1·3593; Brögger, $\grave{c}$ = 1·3605 for natron-catapleiite.

Referred to the *monoclinic* system, Brögger's data give: Axes $\grave{a} : \overset{|}{b} : \grave{c}$ = 1·7356 : 1 : 1·3636; 001 ∧ 100 = *89° 48½′.

Angles: 100 ∧ 110 = *60° 3′, 001 ∧ 101 = 38° 5′, 001 ∧ 011 = 53° 44¾′. Also 110 ∧ $1\bar{1}0$ = 120° 6′, 001 ∧ $\bar{2}01$ = *57° 23½′ 001 ∧ $\bar{2}01$ = 57° 40′, 001 ∧ 111 = 57° 30′, 001 ∧ 110 = 89° 54′, 001 ∧ $\bar{1}11$ = 57° 38′, 111 ∧ $1\bar{1}1$ = 49° 50½′.

The following list gives the observed forms, referred first to the hexagonal system, and second with the proper monoclinic symbols, as interpreted by Brögger.

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| *c* (0001) | = 001 | | | | *y* $(10\bar{1}3)$ | = 203 | 203 | 113 | $\bar{1}13$ |
| *m* $(10\bar{1}0)$ | = 100 | 110 | | | *o* $(10\bar{1}2)$ | = 101 | 101 | 112 | $\bar{1}12$ |
| *a* $(11\bar{2}0)$ | = $\bar{3}10$ | 010 | | | *p* $(10\bar{1}1)$ | = 201 | 201 | 111 | $\bar{1}11$ |
| *π* $(1{\cdot}0{\cdot}\bar{1}{\cdot}72)$ | = 1·0·36 | $\bar{1}$·0·36 | 1·1·72 | $\bar{1}$·1·72 | *x* $(20\bar{2}1)$ | = 401 | $\bar{4}01$ | 221 | $\bar{2}21$ |
| *z* $(1{\cdot}0{\cdot}\bar{1}{\cdot}30)$ | = 1·0·15 | $\bar{1}$·0·15 | 1·1·30 | $\bar{1}$·1·30 | *ρ* $(1{\cdot}1{\cdot}\bar{2}{\cdot}24)$ | = $\bar{3}$·1·24 | 0·1·12 | | |
| *ζ* $(1{\cdot}0{\cdot}\bar{1}{\cdot}24)$ | = 1·0·12 | $\bar{1}$·0·12 | 1·1·24 | $\bar{1}$·1·24 | *u* $(11\bar{2}4)$ | = $\bar{3}14$ | 012 | | |
| *r* $(1{\cdot}0{\cdot}\bar{1}{\cdot}16)$ | = 108 | $\bar{1}08$ | 1·1·16 | $\bar{1}$·1·16 | *s* $(11\bar{2}2)$ | = $\bar{3}12$ | 011 | | |
| *v* $(1{\cdot}0{\cdot}\bar{1}{\cdot}12)$ | = 106 | $\bar{1}06$ | 1·1·12 | $\bar{1}$·1·12 | *ϑ* $(44\bar{8}1)$ | = $\overline{12}$·4·1 | 081 | | |

Also, less certain, *τ* $(11{\cdot}6{\cdot}\bar{17}{\cdot}2)$ = $\bar{8}31$ and 11·165·30, 40·12·5 and $\overline{11}$·165·30, $\overline{40}$·12·5; and *ψ* $(12{\cdot}9{\cdot}\overline{21}{\cdot}2)$ = 6·12·1, etc

Crystals usually thin tabular hexagonal prisms with replaced edges. Twins common: (1) tw. pl. *p* $(10\bar{1}1)$, with $c\underline{c}$ = 64° 52′; (2) tw. pl. $(30\bar{3}2)$ with $c\underline{c}$ = 45° 55′; (3) tw. pl. $(33\bar{6}2)$; (4) *m*; (5) $\underline{c}$.

Cleavage: *m* perfect; also *p* $(10\bar{1}1)$, *o* $(10\bar{1}2)$ imperfect, Dbr. Fracture conchoidal. Brittle. H. = 6. G. = 2·8. Luster nearly dull, weak vitreous on surface of fracture. Color light yellow to yellowish brown, grayish blue, violet. Streak pale yellow. Translucent to opaque. Optically +.

Brögger regards the crystals as originally rhombohedral (tetartohedral), but under a change of conditions they have suffered a secondary molecular rearrangement with the result of bringing them into the monoclinic system.

Sections ‖ *c* in polarized light show the crystals to be commonly trillings, also more complex, with the prism as tw. plane. Axial plane normal, or nearly so, to the edge *c*/*m*. Axial angle about 60°. Heated to 140° sections are isotropic, but become doubly refracting again on cooling. Optically analogous to tridymite, as also in habit of crystals, in twinning, etc.

**Comp.**—Empirical formula, $H_4(Na_2,Ca)ZrSi_3O_{11}$ or $H_2(Na_2,Ca)(Zr(OH)_2)(SiO_3)_3$ as suggested by Brögger. It may also be written $(Na_2,Ca)SiO_3.H_4Zr(SiO_4)_2$. If Na alone is present, the percentage composition is: Silica 46·1, zirconia 28·8, soda 15·9, water 9·2 = 100.

**Var.**—1. *Ordinary.* Contains both sodium and calcium. Color reddish, flesh-red, yellowish red to clear yellow and reddish white; seldom brownish red or dark brown.

2. *Natron-catapleiite,* or soda-catapleiite. Contains only sodium. Color blue to gray and white; on heating the blue color disappears.

**Anal.**—1, 2, Sjögren, l. c. 3, Rg., Min. Ch., 677, 1875. 4, Forsberg, quoted by Bgr., l. c. 5, 6, Weibull, G. För. Förh., **7**, 272, 1884. 7, Forsberg, ibid. 8, 9, Cleve, quoted by Bgr.

| | $SiO_2$ | $ZrO_2$ | $Al_2O_3$ | FeO | CaO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. *Catapleiite.* | 46·83 | 29·81 | 0·45 | 0·63 | 3·61 | 10·83 | 8·86 | = 101·02 |
| 2. " | 46·52 | 29·33 | 1·40 | 0·49 | 4·66 | 10·06 | 9·05 | = 101·51 |
| 3. " | 39·78 | 40·12 | — | — | 3·45 | 7·59 | 9·24 | = 100·18 |
| 4. " | 41·56 | 32·53 | 1·02 | | 5·21 | 9·74 | 9·35 | = 99·41 |
| 5. " | 44·20 | 31·82 | — | 0·22 | 5·31 | 8·93 | 9·26 | = 99·74 |
| 6. " | 44·07 | 32·18 | — | 0·17 | 5·82 | 8·10 | 9·26 | = 99·60 |
| 7. *Natron-catapleiite* | 41·27 | 32·60 | 0·42 | 0·29 | 0·93 | 15·01 | 9·31 | = 99·83 |
| 8. " | 43·92 | 30·80 | — | 0·10 | 0·81 | 15·05 | 9·24 | = 99·92 |
| 9. " | 44·04 | 30·94 | — | 0·10 | 0·87 | 14·94 | 9·24 | = 100·13 |

**Pyr., etc.**—In the closed tube yields water. B.B. in the platinum forceps fuses at 3 to a white enamel; with borax a clear colorless glass. Easily soluble in hydrochloric acid without gelatinizing; the dilute acid solution colors turmeric paper orange-yellow (reaction for zirconia).

**Obs.**—From the island Låven (Lamö) in the Langesund fiord, Norway, with zircon, leucophanite, mosandrite, and tritomite; also on Stokö, Eikaholmen, the Arö islands. *Natron-catapleiite* is only known from the island Lille-Arö, where it occurs with feldspar, elæolite, sodalite, ægirite, låvenite, eucolite, astrophyllite, etc.

Named from *κατα πλεῖον* because always accompanied by a number of rare minerals.

**Alt.**—Pseudomorphs of zircon after catapleiite are noted by Brögger.

---

## 6. Melanocerite Group.

### Hexagonal or Rhombohedral.

**347. Cappelenite** Hexagonal ċ = 1·2903

$RSiO_3.YBO_3$ or $3BaSiO_3.2Y_2(SiO_3)_3.5YBO_3$

**348. Melanocerite** Rhombohedral ċ = 1·2554

$12(H_2,Ca)SiO_3.3(Y,Ce)BO_3.2H_2(Th,Ce)O_2F_2.8(Ce,La,Di)OF$

**349. Caryocerite** Rhombohedral ċ = 1·1845

$6(H_2,Ca)SiO_3.2(Ce,Di,Y)BO_3.3H_2(Ce,Th)O_2F_2.2LaOF$

Steenstrupine

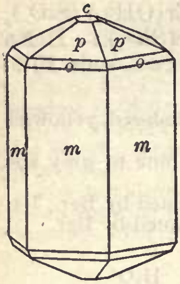
**350. Tritomite** Rhombohedral, hemimorphic $\frac{1}{4}$ ċ = 1·1138

$2(H_2,Na_2,Ca)SiO_3.(Ce,La,Di,Y)BO_3.H_2(Ce,Th)O_2F_2$

---

**347. CAPPELENITE.** *W. C. Brögger,* G. För. Förh., **7**, 599, 1885, **9**, 252, 1887; Zs. Kr., **16**, 462, 1890.

Hexagonal. Axis ċ = 1·2903; 0001 ∧ $10\bar{1}1$ = 56° 7¾′ Brögger.



**Forms:** *c* (0001, *O*), *m* ($10\bar{1}0$, *I*), *p* ($10\bar{1}3$, $\frac{1}{3}$), *o* ($10\bar{1}1$, 1).
Angles: *cp* = 26° 25′, *co* = 56° 8′, *pp′* = *25° 42′, *oo′* = 49° 3½′.

In thick prismatic crystals.

Cleavage none. Fracture conchoidal. Brittle. H. = 6–6·5. G. = 4·407 Cleve. Luster vitreous to greasy. Color greenish brown. Semi-transparent to translucent. Optically –. Double refraction rather strong.

**Comp.**—A boro-silicate of yttrium and barium, probably (Cleve, Bgr.) $RSiO_3.YBO_3$ with R = Ba and $Y_2$( = 3R) chiefly, also $Ca,Na_2,K_2$ in small amount, further Ce,Th( = 2R).

**Anal.**—1, P. T. Cleve, quoted by Brögger, l. c.

| $SiO_2$ | $B_2O_3$ | $\underbrace{CeO_2,ThO_2,Y_2O_3,La_2O_3}$ | BaO | CaO | $Na_2O$ | $K_2O$ | ign. |
|---|---|---|---|---|---|---|---|
| 14·21 | [17·16] | 57·68 | 8·02 | 0·67 | 0·25 | 0·20 | 1·81 = 100 |
| 14·11 | [16·96] | 57·52 | 8·29 | 0·56 | 0·53 | 0·22 | 1·81 = 100 |

Further the rare earths are present as follows: $Y_2O_3$ 91·23, $CeO_2$ 2·24, $La_2O_3$ 5·15, $ThO_2$ 1·38 = 100; or $Y_2O_3$ 52·62, $La_2O_3$ 2·97, $CeO_2$ 1·29, $ThO_2$ 0·80 = 57·68.

**Pyr.**—B.B. swells up and fuses with some difficulty to a white enamel. With fluorite and potassium bisulphate gives the green flame of boron. Easily soluble in hydrochloric acid.

**Obs.**—Occurs in a small vein in the augite-syenite on Lille Arö in the Langesund fiord, southern Norway; it is associated with wöhlerite, rosenbuschite, catapleiite, orangite, låvenite, elæolite, sodalite, etc.

Named after D. Cappelen of Holden, Norway.

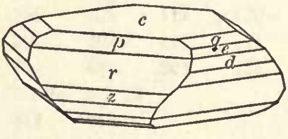
**348. MELANOCERITE.** Melanocerit *Brögger* and *Cleve*, Zs. Kr., **16**, 468, 1890.

Rhombohedral. Axis $\dot{c}$ = 1·25537; 0001 ∧ $10\bar{1}1$ = *55° 24′ Brögger.

**Forms:** *c* (0001, *O*), *ρ* ($10\bar{1}2$, $\frac{1}{2}$), *r* ($10\bar{1}1$, *R*), *z* ($40\bar{4}1$, 4), *q* ($01\bar{1}4$, – $\frac{1}{4}$), *e* ($01\bar{1}2$, – $\frac{1}{2}$), *d* ($02\bar{2}1$, – 2).

*cρ* = 35° 56′ *cq* = 19° 55′ *ρρ′* = 61° 5½′ *ee′* = 61° 5½′
*cr* = *55° 24′ *ce* = 35° 56′ *rr′* = 90° 56′ *dd′* = 109° 54½′
*cz* = 80° 13′ *cd* = 70° 58′ *zz′* = 117° 10′

Crystals tabular in habit; planes sometimes developed with monoclinic symmetry. The fundamental rhombohedron approximates closely to a cube in angle.



Cleavage none. Fracture conchoidal. Brittle. H. = 5–6. G. = 4·129 Cleve. Luster greasy to vitreous. Color deep brown to black. Streak light brown. Transparent with a bright wine-yellow color in splinters and thin sections. Optically uniaxial, negative. In part also isotropic and amorphous (by alteration).

**Comp.**—A fluo-silicate of the cerium and yttrium metals and calcium chiefly, with boron, tantalum, and other elements. Brögger interprets the composition by assuming the presence of the following compounds, which are present in the ratio given:

| $(H_2,Ca)_2Si_2O_6$ | $(Y,Ce)_2B_2O_6$ | $H_4(Ce,Th)_2O_4F_4$ | $(Ce,La,Di)_4O_4F_4$ | $CaTa_2O_6$ | $Ca_2C_2O_6$ |
|---|---|---|---|---|---|
| 0·436 | 0·092 | 0·064 | 0·144 | 0·034 | 0·080 |

The composition, following in the same line (largely hypothetical, to be sure), approximates closely to:

$$12(H_2,Ca)SiO_3.3(Y,Ce)BO_3.2H_2(Th,Ce)O_2F_2.8(Ce,La,Di)OF$$

**Anal.**—Cleve, l. c.

| $SiO_2$ | $ZrO_2$ | $ThO_2$ | $Ta_2O_5$ | $P_2O_5$ | $CO_2$ | $CeO_2$ | $B_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ |
|---|---|---|---|---|---|---|---|---|---|---|
| 13·07 | 0·46 | 1·66 | 3·65 | 1·29 | 1·75 | 3·68 | [3·19] | 0·83 | 2·09 | 1·22 |

| $Ce_2O_3$ | $Di_2O_3$ | $La_2O_3$ | $Y_2O_3$ | CaO | MgO | $Na_2O$ | $H_2O$ | F |
|---|---|---|---|---|---|---|---|---|
| 20·76 | 7·67 | 12·94 | 9·17[a] | 8·62 | 0·14 | 1·45 | 3·01 | 5·78 = 102·43 |

[a] Atomic weight = 104·4.

**Pyr.**—B.B. becomes lighter in color and swells up without fusing. A green flame (boron) with fluorite and potassium bisulphate; with soda, a manganese reaction and with salt of phosphorus a reaction for cerium. Soluble in hot hydrochloric acid with separation of silica.

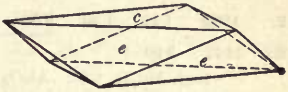
**Obs.**—Occurs very sparingly in the island Kjeö near Barkevik in the Langesund fiord, southern Norway; it is associated with ægirite, barkevikite (and pterolite), lepidomelane, wöhlerite, astrophyllite; also elæolite, leucophanite, spreustein, etc. Probably occurs also in the veins on the Arö-scheeren. Cf. Caryocerite.

**349. CARYOCERITE.** Karyocerit *W. C. Brögger*, Zs. Kr., **16**, 478, 1890.

Rhombohedral. Axis $\dot{c} = 1{\cdot}1845$; $0001 \wedge 10\bar{1}1 = 53° 49\frac{2}{3}'$ Brögger.

**Forms:** *c* (0001, *O*), *e* ($01\bar{1}2$, $-\frac{1}{2}$), *q* ($01\bar{1}4$, $-\frac{1}{4}$). Angles: *cq* = 18° 53′, *ce* = *34° 22′, *ee′* = 58° 32′.

In tabular rhombohedral crystals. Faces brilliant but striated and not yielding good measurements. The occurring rhombohedron is made $-\frac{1}{2}$ ($01\bar{1}2$) in order to bring it into correspondence with the related species melanocerite.



Cleavage none. Fracture conchoidal. Brittle. H. = 5–6. G. = 4·295 Cleve. Luster vitreous to greasy. Color nut-brown. Translucent. Optically isotropic (amorphous), in consequence of alteration.

**Comp.**—Near melanocerite, differing chiefly in containing much more thorium. Brögger, again, assumes the presence of the following compounds, in the ratio given:

| $(H_2,Ca)Si_2O_6$ | $(Ce,Di,Y)_2B_2O_6$ | $H_4(Th,Ce)_2O_4F_4$ | $(La, etc.)_4O_4F_4$ | $CaTa_2O_6$ | $Ca_2C_2O_6$ |
|---|---|---|---|---|---|
| 0·432 | 0·134 | 0·180 | 0 072 | 0·026 | 0·016 |

The composition then approximates closely to:

$$6(H_2,Ca)SiO_3.2(Ce,Di,Y)BO_3.3H_2(Ce,Th)O_2F_2.2LaOF$$

**Anal.**—Cleve, quoted by Brögger, l. c.

| $SiO_2$ | $ZrO_2$ | $ThO_2$ | $Ta_2O_5$ | $P_2O_5$ | $CO_2$ | $CeO_2$ | $B_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ |
|---|---|---|---|---|---|---|---|---|---|---|
| 12·97 | 0·47 | 13·64 | 3·11 | 0·86 | 0·35 | 5·89 | [4·70] | 0·87 | 1·36 | 0·66 |

| $Ce_2O_3$ | $La_2O_3$ | $Di_2O_3$ | $Y_2O_3$ | CaO | MgO | $Na_2O$ | F | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| 14·83 | 14·34 | 6·75 | 2·21[a] | 7·37 | 0·17 | 1·42 | 5·63 | 4·77 = 102·37 |

[a] Atomic weight 101·3.

From the analysis the oxygen-equivalent of the fluorine, 2·37, is to be deducted.

**Pyr.**—See melanocerite.

**Obs.**—Occurs very sparingly in a vein in the augite-syenite of the Langesund fiord, southern Norway, with ægirite, catapleiite, astrophyllite, etc.; stated to have come from the Aröscheeren, or the rock ledges off the west shore of the island Store-Arö.

Named from *κάρυον*, a *nut*, and *cerium*, in allusion to the nut-brown color.

STEENSTRUPINE. *J. Lorenzen*, Medd. Grönl., 1881, Min. Mag., 5, 67. 1882. A mineral allied to melanocerite and caryocerite. Rhombohedral. In indistinct crystals with rounded and roughened faces, somewhat resembling eudialyte. Combinations of *c* and *r*, with *cr* = 52° approx., were noted, with also a second positive, and perhaps also a negative, rhombohedron. Also massive. H. = 4. G. = 3·38. Luster dull. Color brown. Streak brownish, nearly white.

Analysis:

| $SiO_2$ | $TiO_2$ | $ThO_2$ | $Ce_2O_3$ | $(La,Di)_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | CaO | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|
| 27·95 | 0·97 | 7·09 | 10·66 | 17·04 | 2·41 | 9·71 | 4·20 | 3·09 | 7·98 | 7·28 = 98·38 |

The separation of the thoria from the oxides of the cerium group is not regarded as very exact and the composition, consequently, is somewhat doubtful; the mineral, however, obviously approximates closely to the two species preceding, to which it is related also in form.

Entirely decomposed by acids; B.B. fuses easily to a dull gray bead.

Occurs with lepidolite and ægirite in the sodalite-syenite of Kangerdluarsuk, Greenland.

Named after the Danish geologist, K. J. V. Steenstrup of Copenhagen.

**350. TRITOMITE.** Tritomit *Weibye & Berlin*, Pogg., **79**, 299, 1850.

Rhombohedral; hemimorphic (?) Axis $\dot{c}$ = 4·4553. In crystals of acute triangular pyramidal form, approximating to a regular tetrahedron. They are bounded by the planes *c'* (000$\bar{1}$, *O*) and *z* (40$\bar{4}$1, 4). Angles: *c'z* = *101°, *zz'* = 116° 27'.

Cleavage indistinct. H. = 5·5. G. = 4·15–4·25 Bgr. Luster resinous. Color dark brown. Streak yellowish gray. Subtranslucent. Optically isotropic (amorphous[1] ?).

**Comp.**—A fluo-silicate of thorium, the cerium and yttrium metals and calcium, with boron. Essentially, $2(H_2,Na_2,Ca)SiO_3.(Ce,La,Di,Y)BO_3.H_2(Ce,Th,Zr)O_2F_2$, as interpreted by Brögger.

**Anal.**—1, 2, Engström, Inaug. Diss., Upsala, p. 32, 1877. 1, "Brevik," exact locality unknown. G. = 4·178; 2, Barkevig, G. = 4·045. 3, In typical tetrahedral-like crystals: for earlier analyses by Berlin, Forbes, Möller, see 5th Ed., p. 412.

| | $SiO_2$ | $Ta_2O_5$ | $ZrO_2$ | $ThO_2$ | $CeO_2$ | $Ce_2O_3$ | $La_2O_3$ | $Di_2O_3$ | $Y_2O_3$ | $Fe_2O_3$ | $B_2O_3$ | CaO | $Na_2O$ | $H_2O$ | F | |

[a] Incl. $Mn_2O_3$ 0·67, $Al_2O_3$ 1·18. [b] Incl. $Mn_2O_3$ 0·34, $Al_2O_3$ 0·88. [c] Also incl. $ZrO_2$.
Deduct from 1, 1·81 p. c. O = F; from 2, 1·33 p. c.

**Pyr., etc.**—Yields water and gives a weak fluorine reaction; with borax a reddish yellow glass, which is colorless on cooling. With hydrochloric acid in powder yields chlorine, and gelatinizes.

**Obs.**—From the island Låven (Lamö) in the Langesund fiord near Brevik, Norway, with leucophanite, analcite, mosandrite, also ægirite, catapleiite, etc., in a coarse elæolite-syenite; also on Stokö, Arö, the Aröscheeren and near Barkevik.

Named from τρίς, *three-fold*, and τέμνειν, *to cut*, alluding to the trihedral cavities which the crystals leave in the gangue.

**Ref.**—[1] Bgr., Zs. Kr., **16**, 487, 1890. The form has been previously assumed to be that of an isometric tetrahedron; Brögger shows that the isotropic character probably indicates an amorphous condition resulting from alteration, while the crystalline form is either that of a tetragonal sphenoid, or more probably rhombohedral and hemimorphic. The latter view brings it into correspondence with melanocerite, to which it is related in composition.

[2] Determinations of the specific gravity vary widely; Brögger regards 4·15–4·25 as most probably characteristic, and Engström, as noted, gives 4·045, 4·178; earlier results are 3·908 Forbes, 4·16–4·60 Berlin, 4·26 Möller.

Erdmannite. A complex mineral substance from the Langesund fiord, Norway, formerly referred to allanite but, according to Brögger (Zs. Kr., **16**, 497, 1890), in part a mixture of a mineral allied to melanocerite with homilite, in part an altered mineral near homilite. See further under the Datolite Group, p. 507.

---

## Intermediate Silicates.

Silicates intermediate in acidic character between the metasilicates and orthosilicates; oxygen ratio of silicon to bases between 2 : 1 and 1 : 1.

A number of other species, strictly falling here, are included among the orthosilicates in order to exhibit their true group-relations; for example, nephelite obviously belongs with the hexagonal group, having the general composition $\overset{\text{I}}{R}AlSiO_4$, etc.

### 1. Leucophanite Group.

| | | | |
|---|---|---|---|
| **351.** | **Leucophanite**<br>$NaCaBeFSi_2O_6$ | Orthorhombic, hemihedral | $\breve{a} : \bar{b} : \dot{c}$ = 0·9939 : 1 : 0·6722 |
| **352.** | **Meliphanite**<br>$NaCa_2Be_2FSi_3O_{10}$ | Tetragonal, hemihedral | $\dot{c}$ = 0·6584 |

The form of leucophanite approximates closely to that of the tetragonal meliphanite

## 2. Iolite Group.

| | | | | $\breve{a}:\bar{b}:\acute{c}$ |
|---|---|---|---|---|
| 353. | **Iolite** | $H_2(Mg,Fe)_4Al_8Si_{10}O_{37}$ | Orthorhombic | 0·5871 : 1 : 0·5585 |

## 3. Barysilite Group.

Silicates containing lead.

| | | | |
|---|---|---|---|
| 354. | **Barysilite** | $Pb_3Si_2O_7$ | Hexagonal |
| 355. | **Ganomalite** | $Pb_3(Ca,Mn)_2Si_3O_{11}$ | Tetragonal |
| 356. | **Hyalotekite** | $R_{18}B_4Si_{24}O_{70}F$ or, approx., $Ca_3Ba_3Pb_3B_2(SiO_3)_{12}$ | |

---

## 1. Leucophanite Group.

**351. LEUCOPHANITE.** Leukophan *Esmark*. Erdmann, Ak. H. Stockh., 191, 1840; Tamnau, Pogg., 48, 504, 1839. Leucophane. Leucofanite.

Orthorhombic; hemihedral. Axes $\breve{a}:\bar{b}:\acute{c}$ = 0·99391 : 1 : 0·67217 Brögger[1].

100 ∧ 110 = 44° 49½′, 001 ∧ 101 = 34° 4⅙′, 001 ∧ 011 = 33° 54½′.

Forms[1]:
*a* (100, $i\text{-}\bar{i}$)
*b* (010, $i\text{-}\breve{i}$)
*c* (001, *O*)
*k* (310, $i\text{-}\bar{3}$)

*p* (111, 1)
*x* (221, 2)
*ξ*, ($1\bar{1}9$, $-\frac{1}{9}$)
*ψ*, ($1\bar{1}8$, $-\frac{1}{8}$)
*χ*, ($1\bar{1}7$, $-\frac{1}{7}$)
*φ*, ($1\bar{1}6$, $-\frac{1}{6}$)?
*s*, ($2\bar{2}3$, $-\frac{2}{3}$)
*p*, ($1\bar{1}1$, − 1)
*x*, ($2\bar{2}1$, − 2)
*t* (212, $1\text{-}\bar{2}$)
*t*, ($2\bar{1}2$, $-1\text{-}\bar{2}$)
*ρ* (8·7·12, $\frac{2}{3}\text{-}\frac{8}{7}$)
*τ* (122, $1\text{-}\breve{2}$)

Angles: *mm‴* = *89° 39′, *co* = 53° 31½′, *oo‴* = *72° 57⅙′, *cx* = 62° 20′, *bx* = 51° 22′, *ax* = 51° 5′, *mx* = 27° 40′, *ox* = 38° 38′, *mo* = 55° 14′.

In crystals usually tabular ∥ *c* and commonly showing sphenoidal hemihedrism in the distribution of the pyramidal planes; with this the form of the etching-figures agrees (Bgr.). Often twins with tw. pl. *m* and *c*; usually penetration-twins by which in each quadrant a right and left individual are brought together in twinning position and complementary to each other, with *c* as comp.-face. Also in prismatic crystals (∥ *m*) which are penetration-fourlings, analogous to harmotome, with tw. pl. *b*. Massive in columnar or laminated forms.

Cleavage: *c* perfect; *a*, *o* (201) distinct; also *b*, *δ* (021). Fracture conchoidal. Very brittle. H. = 4. G. = 2·959 Bgr.; 2·964 Rg. Luster vitreous. Color whitish green, greenish white, deep green with a yellow tinge, wine-yellow; thin fragments transparent and colorless. Strongly phosphorescent with a bluish light, whether heated or struck. Pyroelectric.

Optically −. Ax. pl. ∥ *a*. $Bx_a \perp c$. Dispersion $\rho > v$, weak. Axial angles, Bgr.:

$2E_r$ = 74° 24½′ Li   $2E_y$ = 74° 15′ Na   $2E_{gr}$ = 74° 8′

$\alpha_r = 1·5680$   $\beta_r = 1·5909$   $\gamma_r = 1·5948$
$\alpha_y = 1·5709$   $\beta_y = 1·5948$   $\gamma_y = 1·5979$   . $2V_y$ = 39° 2′

**Comp.**—$Na(BeF)Ca(SiO_3)_2$ = Silica 49·4, glucina 10·3, lime 23·0, soda 12·8, fluorine 7·9 = 103·4, deduct 3·4 (O = 2F) = 100.

This formula is that given by Brögger, see further under the following species, meliphanite.

Anal.—1, Erdmann, l. c. 2 Rg. Pogg., 98, 257, 1856. 3–5, Id., Zs. G. Ges., 28, 59, 1876. 6, Id. mean of 3–5 as given in Min. Ch., Erg., 152, 1886. 7, Bäckström, Zs. Kr., 16, 286, 1890.

[a] Incl. 0·17 MgO. [b] MgO 0·27.

**Pyr., etc.**—In the closed tube whitens and phosphoresces with a bluish light. B.B. in the forceps phosphoresces and fuses with intumescence at 3 to a clear colorless glass, which becomes opaque-white on flaming; imparts an intense yellow color to the flame. Fused with salt of phosphorus in the open tube gives the reaction for fluorine.

**Obs.**—Occurs in pegmatyte veins in augite-syenite with elæolite, ægirite, mosandrite, astrophyllite, etc., on the small islet Låven, near the mouth of the Langesund fiord in Norway; also from Stokö and other islands in the neighborhood.

Named from λευκός, *white*, and φαίνεσθαι, *to appear*, because it presents a whitish reflection in certain lights.

**Ref.**—[1] Bgr., Zs. Kr., **16**, 246, 1890. See also Greg, Phil. Mag., **9**, 510, 1855; Nd., Öfv. Ak. Stockh., **27**, 557, 1870; Lang, Min. Mitth., 82, 1871; Bertrand, Ann. Mines, 3, 24, 1873, and Phil. Mag., 3, 357, 1877; Groth, Zs. Kr., **2**, 199, 1878. The form, which approximates closely to the tetragonal type, has been regarded as monoclinic (cf. Btd., Groth).

**352. MELIPHANITE.** Melinophan *Scheerer*, J. pr. Ch., **55**, 449, 1852. Meliphane *Dana*, Am. J. Sc., **44**, 405, 1867.

Tetragonal and tetartohedral. Axis $\dot{c} = 0·65843$; $001 \wedge 101 = 33° 21\frac{3}{4}'$ Bertrand[1].

**Forms**: *c* (001, *O*), *a* (100, *i-i*), *k* (310, *i*-3), *e* (101, 1-*i*), *o* (201, 2-*i*), *p* (111, 1), *v* (214, ½-2).

Angles: *ee'* = 44° 14', *ee''* = 66° 43½', *co* = 52° 47', *pp'* = 57° 37', *pp''* = *85° 55'.

Commonly in obtuse octahedrons with *p* (111) prominent, but tetartohedral in the distribution of the planes, as also in the want of symmetry of the etching-figures (Bgr.). Also massive, and consisting sometimes of plates or lamellæ.

Cleavage: *c* distinct. Brittle. H. = 5–5·5. G. = 3·006 Bgr.; 3·018 Rg. Luster vitreous. Color sulphur-, citron-, or honey-yellow; also flesh-red, brick-red. Transparent to translucent. Optically —. Pleochroism distinct. Double refraction strong. Indices, Bgr.:

$\omega_r = 1·5912$ red glass $\omega_y = 1·5934$ Na $\omega_{gr} = 1·5975$ Tl
$\epsilon_r = 1·6097$ " " $\epsilon_y = 1·6126$ Na $\epsilon_{gr} = 1·6161$ Tl

**Comp.**—A fluo-silicate of beryllium, calcium, and sodium near leucophanite. Formula $NaCa_2Be_2FSi_5O_{10}$ = Silica 46·9, glucina 13·1, lime 29·1, soda 8·1, fluorine 5·0 = 102·2, deduct 2·2 (O = 2F) = 100. Aluminium may also be present.

The above formula is given by Brögger (with $3Be = Al_2$ which somewhat reduces the excess of silica), who further writes it $Ca_4Be_2(BeF)_2Na(SiO_3)_4.(SiO_4)_2$ or as a metasilicate, $Na_2(BeF)_2(Ca_2O)_2Be_2(SiO_3)_6$; that for leucophanite being written for sake of comparison $Al_2Na_3(BeF)_3Ca_3(SiO_3)_6$.

Rammelsberg suggests $6RSiO_3.R_2SiO_4 + 3NaF$ for leucophanite, and $RSiO_3.R_2SiO_4 + 6NaF$ for meliphanite.

**Anal.**—1, Rg., Pogg., **98**, 257, 1856. 2–5, Id., Zs. G. Ges., **28**, 61, 1876. 6, Bäckström, Zs. Kr., **16**, 288 1890.

| | $SiO_2$ | $Al_2O_3$ | BeO | CaO | $Na_2O$ | $K_2O$ | F | |
|---|---|---|---|---|---|---|---|---|
| 1. Fredriksvärn | 43·66 | 1·57[a] | 11·74 | 26·85[b] | 8·55 | 1·40 | 5·73 | $H_2O$ 0·30 = 99·80 |

[a] With $Fe_2O_3$ ($Mn_2O_3$). [b] MgO 0·11. [c] With $Fe_2O_3$.

**Pyr., etc.**—B.B. in the forceps does not phosphoresce, fuses with intumescence to a white enamel; in other respects resembles leucophane.

**Obs.**—From the augite-syenite of southern Norway, near Fredriksvärn, with elæolite, mica, fluorite; also from several of the islands of the Langesund fiord, at Stoksund on Stokö, Langodden, etc. Often associated with elæolite, homilite, erdmannite, fluorite, zircon, löllingite, etc. It does not accompany leucophanite, but appears to take its place.

Named from μέλι, *honey*, and φαίνεσθαι, *to appear*, from the honey-yellow color. [Scheerer miswrote the word *melinophane*, which would come from μέλινος, *ashen*, or μελινη, *millet.*] The dropping of the *t* of the genitive, as done above, has classical authority.

**Ref.**—[1] C. R., **83**, 711, 1876; also Nd., Öfv. Ak. Stockh., **27**, 556, 1870, who describes tabular crystals with two pyramids, $cp = 47° 51'$, and $cq = 21° 42'$, not readily corresponding to Bertrand's form; Bgr., Zs. Kr., **16**, 279, 1890.

## 2. Iolite Group.

**353. IOLITE.** Spanischer Lazulith *v. Schlotheim*, Hoff, Mag. Min., **1**, 169, 1801. Iolith (fr. Spain) *Wern.; Karst.* (with descr.), Tab., 46, 92, 1808. Iolithe *H.*, Tabl., 61, 221, 1809. *u* (134, $\frac{3}{4}$-$\breve{3}$)
*o* (131, 3-$\breve{3}$)

$mm''' = {}^*60° 50'$
$dd' = 59° 10'$
$ff' = 50° 52\frac{1}{2}'$
$ee' = 87° 8'$
$ll' = 31° 12'$
$nn' = 58° 22'$
$pp' = 96° 20'$
$qq' = 131° 46'$
$cs = 28° 53'$
$cr = 47° 48'$
$ch = 65° 37'$
$rr' = 79° 25'$
$uu' = 24° 45'$
$oo' = 51° 59'$
$ss''' = 28° 18\frac{1}{2}'$
$rr''' = 44° 4'$
$hh''' = 54° 55'$

Twins: (1) tw. pl. *m*, often repeated giving pseudo-hexagonal forms; also as enclosed twinning lamellæ. (2) Tw. pl. *d* (130)[3], also pseudo-hexagonal. Habit short prismatic; faces in zone *ab*, vertically striated. As embedded grains; also massive, compact.

Cleavage: *b* distinct; *a* and *c* indistinct. Crystals often show a lamellar structure ∥ *c*, especially when slightly altered. Fracture subconchoidal. Brittle. H. = 7–7·5. G. = 2·60–2·66. Luster vitreous. Color various shades of blue, light or dark, smoky blue. Transparent to translucent.

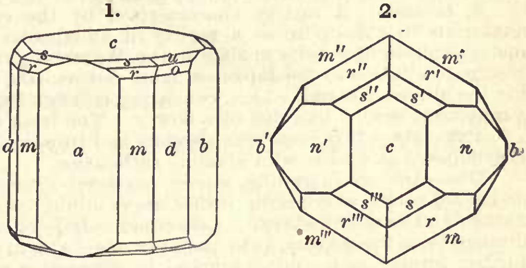

Fig. 1, Laach, Rath. 2, Miller.

[4] Pleochroism strongly marked except in thin sections. Axial colors variable, as given by Haidinger:

| | $\mathfrak{c} = \bar{b}$ | $\mathfrak{b} = \breve{a}$ | $\mathfrak{a} = \acute{c}$ |
|---|---|---|---|
| Bodenmais | dark Berlin-blue | light Berlin-blue | yellowish white |
| Arendal | dark blue | light blue | yellowish white |
| Orijärvi | dark Berlin-blue | plum-blue | reddish clove-brown |
| Ceylon | light Berlin-blue | bluish white | yellowish white |
| Haddam | pale blue | nearly white | light yellowish white |

Also for the planes: *a* bluish white, *b* yellowish white, *c* blue. Absorption $\mathfrak{c}\ (\bar{b}) > \mathfrak{b}\ (\breve{a}) > \mathfrak{a}\ (\acute{c})$. Pleochroic halos common, often bright yellow; best seen in sections ‖ $\dot{c}$. Exhibits idiophanous figures[5], analogous to andalusite, epidote, etc. Optically −. Ax. pl. ‖ *a*. Bx ⊥ *c*. Dispersion feeble, $\rho < v$. Refractive indices (for orange), Dx.[6]:

| | | | | | |
|---|---|---|---|---|---|

Heat increases the axial angle perceptibly, *e.g.*, from 2E = 63° 56′ at 8°·8 C. to 69° 8′ at 95°·5, and 71° 40′ at 150°·8, for red rays, Dx.

**Comp.**—$H_2(Mg,Fe)_4Al_8Si_{10}O_{37}$ or $H_2O.4(Mg,FeO).4Al_2O_3.10SiO_2$ Farrington. If Mg : Fe = 7 : 2, the percentage composition is: Silica 49·4, alumina 33·6, iron protoxide 5·3, magnesia 10·2, water 1·5 = 100. Ferrous iron replaces part of the magnesium. There has been some doubt expressed (Rg.) as to the state of oxidation of the iron. Calcium is also present in small amount.

[a] $Fe_2O_3$ as given by Rg.

**Var.**—1. *Ordinary.* In short prismatic crystals, six- or twelve-sided, often with rounded edges; also massive or in embedded grains.

2. *Cerasite.* A variety characterized by the constant and regular presence of inclusions, analogous to chiastolite as a variety of andalusite; pleochroism weak. Produced by contact metamorphism of granite in slate in the Watarase-gawa region, Japan. Named from κέρασος, *cherry*, in allusion to the Japanese name *Sakura-ishi*, or cherry-stone, given to the rock containing the altered mineral, which, consisting chiefly of mica, shows a hexagonal radiate structure in a transverse section like that of a flower. The fresh mineral (anal. 8) shows the same structure.

**Pyr., etc.**—B.B. loses transparency and fuses at 5–5·5. Only partially decomposed by acids. Decomposed on fusion with alkaline carbonates.

**Obs.**—Occurs in granite, gneiss (*cordierite-gneiss*), hornblendic, chloritic and talcose schist, and allied rocks, with quartz, orthoclase or albite, tourmaline, hornblende, andalusite, sillimanite, garnet, and sometimes beryl. Less commonly in or connected with igneous rocks, thus formed directly from the magma, as in andesyte, etc.; also in ejected masses (in fragments of older rocks); further formed as a contact-mineral in connection with cruptive dikes, as in slates adjoining granite (cf. cerasite above), or as microscopic crystals in vitrified sandstone near basalt (cf. Zirkel, Jb. Min., 1, 109, 1891).

At Bodenmais, Bavaria, it is met with in granite, in crystals, along with pyrrhotite, sphalerite, chalcopyrite; the variety is the *peliom* of Werner, named from πέλιος, in allusion to its smoky blue color. It occurs in the andesytes of Hungary (Szabó, Jb. Min., Beil., 1, 302, 1881). In quartz at Ujordlersoak in Greenland; in the andesytes of Cabo de Gata, in Spain; at Kragerö, in Norway; Orijärvi, in Finland (*steinheilite*); Tunaberg, in Sweden; Finspaong, in Ostgothland; Brunhult, in Södermanland; Falun (*hard fahlunite*); in ejected masses of gneiss at the Laacher See; at Campiglia Maritima, Tuscany, in a trachytic rock, containing also mica, quartz, and sanidine. In colorless crystals (G. = 2·67) from Brazil. Ceylon affords a transparent variety, in small rolled masses of an intense blue color, the *saphir d'eau* of jewellers. In Japan along the Watarase-gawa (*cerasite*), on the borders of the provinces Kōdsuke and Shimotsuke, as noted above and at other points; also altered to a micaceous mineral in a dark slate near Kameoka, in the province of Tamba; further in ejected masses from Asama-yama.

At Haddam, Conn., associated with tourmaline in a granitic vein in gneiss; sparingly at the chrysoberyl locality, in an altered or fahlunite condition; abundant in quartz with garnet and yellowish green feldspar, near the Norwich and Worcester Railway, between the Shetucket and

Quinnebaug, where the gneiss has been quarried for the road; in gneiss near Guilford, Conn. At Brimfield, Mass., on the road leading to Warren, near Sam Patrick's with adularia, in gneiss; also good at Richmond, N. H., in talcose rock, along with anthophyllite.

Named *Iolite* from ἴον, *violet*, and λίθος, *stone; Dichroite* (from δίχροος, *two-colored*), from its dichroism; *Cordierite*, after Cordier, the French geologist (1777–1861), who first studied the crystals of the species; *Steinheilite* by Gadolin after Mr. Steinheil.

**Alt.**—The alteration of iolite takes place so readily by ordinary exposure, that the mineral is most commonly found in an altered state, or enclosed in the altered iolite. This change may be a simple hydration; or a removal of part of the protoxide bases by carbon dioxide; or the introduction of oxide of iron; or of alkalies, forming pinite and mica. The first step in the change consists in a division of the prisms of iolite into plates parallel to the base, and a pearly foliation of the surfaces of these plates; with a change of color to grayish green and greenish gray, and sometimes brownish gray. As the alteration proceeds, the foliation becomes more complete; afterward it may be lost. The mineral in this altered condition has many names: as *hydrous iolite* (incl. *bonsdorffite* and *auralite*) from Åbo, Finland, anal. 2; *fahlunite* (and *weissite*?) from Falun, Sweden, anal. 1, also *pyrargillite* from Helsingfors; *esmarkite* and *praseolite* from near Brevik, Norway, also *raumite* from Raumo, Finland, and *peplolite* from Ramsberg, Sweden; *chlorophyllite* from Unity, Me., anal. 3; *aspasiolite*, anal. 4; and *polychroilite* from Kragerö, further, the alkaline kinds, *pinite, cataspilite, gigantolite, iberite*, which are mentioned more particularly, with analyses, under the Mica Group, wh. see. See further fahlunite, etc., 5th Ed., pp. 484–486, also a review of the subject by Wichmann, Zs. G. Ges., **26**, 675, 1874.

The following are analyses of some of the above mentioned alteration products of iolite: 1, Trolle Wachmeister, Ak. H. Stockh., 213, 1827. 2, Malmgren, Vh. Min. Ges., 152, 1862. 3, Rg., Min. Ch., 833, 1860. 4, Scheerer, Pogg., **68**, 323, 1846.

## 3. Barysilite Group.

**354. BARYSILITE.** Barysil *A. Sjögren* and *C. H. Lundström*, Öfv. Ak. Stockh., **45**, 7, 1888.

Hexagonal. In embedded masses with curved lamellar structure.

Cleavage: basal, distinct; prismatic less so. H. = 3. G. = 6·11; 6·55. Fracture uneven. Brittle. Luster pearly on cleavage surface. Color white; tarnishing on exposure. Translucent. Optically uniaxial, negative.

**Comp.**—$Pb_3Si_2O_7$ or $3PbO.2SiO_2$ = Silica 15·2, lead protoxide 84·8 = 100. The lead is replaced in part by manganese, calcium, magnesium.

**Anal.**—Sjögren and Lundström.

| | | $SiO_2$ | PbO | MnO | FeO | CaO | MgO | ign. | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 6·11 | 17·85 | 73·39 | 4·14 | 0·44 | 1·29 | 1·09 | 1·20 | Cl *tr.* = 99·40 |
| 2. | G. = 6·55 $\frac{2}{2}$ | 16·98 | 77·84 | 3·49 | 0·16 | 0·41 | 0·58 | 0·66 | = 100·12 |
| 3. | | 16·83 | 77·64 | 3·67 | 0·12 | 0·23 | 0·57 | 0·54 | Cl *tr.* = 99·60 |

**Pyr.**—Decrepitates and fuses very easily B.B. to a clear brown glass; reacts for lead and manganese. Dissolves with gelatinization in nitric acid; also in hydrochloric acid with separation of lead chloride.

**Obs.**—Occurs scattered through iron ore with calcite, yellow garnet, tephroite, and galena at the Harstig mine, Pajsberg, Wermland, Sweden.

**355. GANOMALITE.** *A. E. Nordenskiöld,* G. För. Förh., **3**, 121, 1876, **3**, 382, 1877; *A. Sjögren,* ib., **6**, 531, 1883.

Tetragonal[1]. In prismatic crystals with the forms:

*c* (001, *O*), *m* (110, *I*), *h* (410, *i*-4)?, *p* (111, 1), *cp* = 45° approx., whence $\dot{c}$ = 0·707.

Also massive, granular.

Cleavage: *m* and *c* distinct. Fracture uneven. Very brittle. H.=3. G.=5·74 Lindström; 4·98 Nd. Luster resinous to vitreous. Colorless to gray. Optically positive. Double refraction strong.

**Comp.**—$Pb_3Si_2O_7.(Ca,Mn)_2SiO_4$ or $3PbO.2(Ca,Mn)O.3SiO_2$. If Ca : Mn = 5 : 1, this requires: Silica 18·7, lead protoxide 69·2, manganese protoxide 2·4, lime 9·7 = 100.

**Anal.**—1, 2, Wiborgh, G. För. Förh., **6**, 537, 1883. 3, G. Lindström, ib., p. 662; three determinations of the specific gravity gave: 5·722, 5·730, 5·762.

| | $SiO_2$ | PbO | MnO | CaO | |
|---|---|---|---|---|---|
| 1. | 20·22 | 69·95 | — | 9·27 | = 99·44 |
| 2. | 20·59 | 68·89 | — | 10·52 | = 100 |
| 3. Jakobsberg G. = 5·74 | 18·33 | 68·80 | 2·29 | 9·34 | ign. 0·57, X[a] 0·70 = 100·03 |

[a] X = $Al_2O_3$ 0·07, $Fe_2O_3$ 0·12, CuO 0·02, MgO 0·11, alk. 0·10, $P_2O_5$ 0·04, Cl 0·24.

**Pyr.**—B.B. fuses easily to a clear glass, which in R.F. is colored black by reduced lead. On charcoal with soda a lead globule, and a coating of lead oxide. Easily soluble in nitric acid, with the separation of gelatinous silica.

**Obs.**—Occurs very sparingly with tephroite (which it closely resembles), native lead, calcite, and jacobsite, at Långban, Wermland, Sweden. Also from Jakobsberg, Nordmark, mixed with a brown mica (manganophyllite), and associated with calcite and jakobsite. Named from *γάνωμα, luster*.

An earlier approximate analysis by Lindström of the Långban mineral (quoted by Nd.) gave: $SiO_2$ 34·55, PbO 34·89, MnO 20·01, CaO 4·89, MgO 3·68, alk. and loss 1·98 = 100. Cf. ref.[1]. It does not seem certain that the two minerals are identical.

Nordenskiöld (ib., p. 384) mentions the occurrence at Långban of a second lead silicate, very similar in appearance and blowpipe reactions to the above, but with two distinct cleavages, at an angle of 75° 27′. The material available was too scanty for full examination, but he suggests that it may be a more distinctly crystallized variety of ganomalite.

**Ref.**—[1] Nd., A. Sj., l. c.; biaxial with small angle, Dx., Bull. Soc. Min., **1**, 8, 1878.

**356. HYALOTEKITE.** *A. E. Nordenskiöld,* G. För. Förh., **3**, 382, 1877.

Massive. Coarsely crystalline.

Cleavage easy in two directions, at an angle of approximately 90°; also less easy in a third direction, in the same zone (Dx.). Brittle. H. = 5–5·5. G.=3·81. Luster vitreous to greasy. Color white to pearly gray. Transparent in very thin plates. Optically biaxial, positive. Ax. pl. ∥ zone-axis of the cleavages. $2H_r$=98°–99°, Dx.[1]

**Comp.**—Approximately $R_9B_2(SiO_3)_{12}$. Lindström's analysis gives $16RO.2B_2O_3.24SiO_2.F$. Here R=Pb : Ba : Ca = 0·225 : 0·262 : 0·279; also small quantities of BeO, $K_2O$, etc. Groth suggests $HR_4B(SiO_3)_6$ with F replacing most of the (OH).

**Anal.**—G. Lindström, Öfv. Ak. Stockh., **44**, 589, 1887.

| $SiO_2$ | $B_2O_3$ | PbO | BaO | CaO | F |
|---|---|---|---|---|---|
| 39·47 | 3·73 | 25·11 | 20·08 | 7·82 | 0·99 ign. 0·59, X[a] 2·58 = 100·37 |

[a] X = CuO 0·09, MnO 0·29, BeO 0·75, MgO 0·09, $K_2O$ 0·89, Cl 0·06, $Na_2O$ 0·17, $Al_2O_3$ 0·18, $Fe_2O_3$ 0·06.

An earlier incomplete analysis (Nd.) gave: $SiO_2$ 39·62, PbO 25·30, BaO 20·66, CaO 7·00, ign. 0·82, $Al_2O_3$, $K_2O$, etc., *tr*.

**Pyr., etc.**—B.B. fuses to a clear glass, which in R.F. becomes blackened with reduced lead. On charcoal with soda in small amount fuses to a clear glass; with more soda in R.F. gives a lead globule and a coating of lead oxide. In salt of phosphorus dissolves, leaving a skeleton of silica. Insoluble in hydrochloric or sulphuric acids.

**Obs.**—Occurs sparingly in a grayish white feldspar, with hedyphane and schefferite, at Långban, Wermland, Sweden. Named from *ὕαλος, glass,* and *τήκειν, to melt.*

**Ref.**—[1] Bull. Soc. Min., **1**, 9, 1878.

## III. Orthosilicates. $R_2SiO_4$.

Salts of Orthosilicic Acid, $H_4SiO_4$; characterized by an oxygen ratio of 1 : 1 for silicon to bases.

The following list includes the prominent groups among the Orthosilicates.

A number of basic orthosilicates are here included, which yield water upon ignition; also others which are more or less basic than a normal orthosilicate, but which are of necessity introduced here in the classification, because of their relationship to other normal salts. The MICA GROUP is so closely related to many Hydrous Silicates that (with also Talc, Kaolinite, and some others) it is included under the latter head.

1. **Nephelite Group.** Hexagonal.
2. **Sodalite Group.** Isometric.
3. **Helvite Group.** Isometric, tetrahedral.
4. **Garnet Group.** Isometric.
5. **Chrysolite Group.** Orthorhombic.
6. **Phenacite Group.** Rhombohedral.
7. **Scapolite Group.** Tetragonal.
8. **Melilite Group.** Tetragonal.
9. **Vesuvianite Group.** Tetragonal.
10. **Zircon Group.** Tetragonal.
11. **Danburite Group.** Orthorhombic.
12. **Datolite Group.** Monoclinic.
13. **Epidote Group.** Monoclinic.
14. **Axinite Group.** Triclinic.

---

### 1. Nephelite Group. Hexagonal.

Typical formula $\overset{\mathrm{I}}{\dot{R}}AlSiO_4$.

| | | | |

Etching experiments seem to prove the existence of pyramidal hemihedrism with hemimorphism in the direction of $\dot{c}$; also of twinning with *a* and *c* as tw.-planes, Baumh.[3]

**Var.**—1. *Nephelite, Glassy.* Usually in small glassy crystals or grains, transparent with vitreous luster, first found on Mte. Somma. G. = 2·56, Vesuvius, Scheerer; 2·637, ib., Breith. Characteristic particularly of younger eruptive rocks and lavas; often in crystals also forming an unindividualized ground-mass (*nephelinitoid*).

2. *Elæolite.* In large coarse crystals, or more commonly massive, with a greasy luster, and reddish, greenish, brownish or gray in color. Usually clouded by minute inclusions. G. = 2·597 Miask, Breith.; 2·617 Brevik, Scheerer; 2·612 Laurvik, Bgr.; 2·65 Arkansas, Smith & Brush. Characteristic of granular crystalline rocks, syenite, etc.

**Comp.**—$\overset{\text{I}}{R}_8Al_8Si_9O_{34}$; if $\overset{\text{I}}{R}$ = Na : K = 3 : 1, this is equivalent to $3Na_2O.K_2O.4Al_2O_3.9SiO_2$ = Silica 44·0, alumina 33·2, soda 15·1, potash 7·7 = 100. In most analyses Na : K = 4 : 1 or 5 : 1.

The above is the formula of Scheerer. Cf. also Rg., Ber. Ak. Berlin, 695, 1876, Min. Ch., Erg., 170, 1886; Rauff, Zs. Kr., **2**, 454, 1878; Doelter, ib., **9**, 321, 1884.

From synthetic experiments, yielding crystals like nephelite, with the composition $NaAlSiO_4$ or $Na_2O.Al_2O_3.2SiO_2$. Doelter decides that a natural soda-nephelite would be an orthosilicate with this formula, while the higher silica in the potash varieties may be explained by the presence, in molecular combination, of $KAlSi_2O_6$ or $K_2O.Al_2O_3.4SiO_2$ (= leucite). This was also suggested by Rammelsberg, and seems very probable, although not agreeing strictly with Scheerer's formula above. It is to be noted that the other species of the group are normal orthosilicates, viz., eucryptite $LiAlSiO_4$, and kaliophilite $KAlSiO_4$.

**Anal.**—1–3, Scheerer, Pogg., **49**, 359, 1840, also other analyses. 4, Rg., Min. Ch., 446, 1875. 5, Rg., l. c., 1876. 6, Rauff, l. c. 7, Jannettaz, Bull. Soc. **Pyr., etc.**—B.B. fuses quietly at 3·5 to a colorless glass. Gelatinizes with acids.

**Obs.**—Nephelite occurs both in ancient and modern volcanic rocks, and also in crystalline rocks allied to granite and gneiss; in recent volcanic rocks it is in glassy crystals or grains often associated with glassy feldspar or sanidine, as in phonolyte, or with a triclinic feldspar in teschenyte, etc., or without feldspar in nephelinyte and nephelinbasalt, as that of Katzenbuckel, near Heidelberg. In the older igneous rocks the variety elæolite is present, often with orthoclase, as in elæolite-syenite. No sharp distinction can be made, however, between the plutonic or intrusive granitoid rocks carrying nephelite (elæolite) and surface or effusive rocks; thus Derby shows that in Brazil (Minas Geraes, São Paulo, etc.) both types pass into each other (Q. J. G. Soc., **43**, 457, 1887, and Dec. 19, 1890).

A granitoid rock found near Miask, in which elæolite is prominent, has been named *miascyte*, from its locality. A rock composed of orthoclase, elæolite, and sodalite, from Ditró in Transylvania, is the *ditröyte* of Tschermak. The zircon-syenite or augite-syenite of Norway contains much elæolite, and is hence often called also elæolite-syenite.

Nephelite occurs in crystals in the older lavas of Mte. Somma, with mica, vesuvianite, etc.; at Capo di Bove, near Rome (the locality of the *pseudo-nepheline*); in the basalt of Katzenbuckel, near Heidelberg; at Meiches in Hesse; Aussig in Bohemia; Löbau in Saxony; in granular masses embedded in the basalt of Denise near Puy, Haute Loire. Phonolytes carrying nephelite occur on Fernando de Noronha and also, with the granitoid foyaytes, extensively in Brazil in the provinces of Minas Geraes, São Paulo, Rio de Janeiro (cf. Derby, l. c., *et al.*).

Elæolite is found at Stavern and Fredriksvärn, Norway, and at many points in the region of the Langesund fiord, where the elæolite-syenite is characterized by the number and variety of rare minerals which it contains (see Brögger, Zs. Kr., **16**, 1890); in the Ilmen Mts., Ural, along with white feldspar, brown hexagonal mica, zircon, pyrochlore, etc.; in the Tunkinsk Mts., Siberia, with graphite, cancrinite, zircon. In the sodalite-syenite of Tunugdliarfik and Kangerdluarsuk in south Greenland. In the elæolite-syenite or *foyayte* of Sierra de Monchique, southern Portugal.

Elæolite occurs massive and crystallized at Litchfield, Me., with cancrinite; in the Ozark Mts., near Magnet Cove, Arkansas, with brookite, schorlomite, eudialyte, and many rare species; in a boulder, with sodalite, at Salem, Mass. Elæolite-syenite is also found near Beemersville, northern N. J. A nephelite-basalt forms the mass of Pilot Knob, near Austin, Tex. Other nephelite rocks occur in the Kawsoh Mts., Nev.; Elkhead Mts., Col.; and the Peloncillo Mts., Arizona. A granular crystalline rock (theralite Rosenb.), consisting of nephelite and plagioclase, forms intrusive masses in the Crazy Mts., Montana. An elæolite-syenite containing sodalite occurs in Brome Mt., Brome Co.; also near Montreal and at Belœil, Rouville Co., Quebec, Canada; further stated (Hunt) to occur in boulders on Pic island, L. Superior.

Named *nepheline* by Haüy (1801), from νεφελή, *a cloud*, in allusion to its becoming cloudy when immersed in strong acid; *elæolite* (by Klaproth), from ἐλαίον, *oil*, in allusion to its greasy luster, the variety having been made a distinct species earlier by Werner (1808), under the German name of *Fettstein*. The name *sommite*, derived from the Vesuvian locality, given in 1797 by Delamétherie, has the priority, but Werner early adopted Haüy's name, and later authors have all taken the same course. Moreover sommite probably included some of the related species occurring at Vesuvius, as microsommite, etc.

The *gabronite* (gabbronite) of Schumacher, 1801, the dichter Wernerit of Hausmann, 1811, which has been referred to the scapolites (see 5th Ed., p. 324) was elæolite according to Brögger.

A mineral from Norway, of a yellowish brown color, called *phonite*, is very much like elæolite (Dx.).

**Alt.**—Nephelite or elæolite is liable to ready alteration, and usually produces a zeolite, as thomsonite or analcite. The *ozarkite* of Shepard, according to Smith and Brush, is thomsonite (q.v.), and its situation in cavities in elæolite shows that it is a product of alteration.

Brögger describes the change of the elæolite of the augite-syenite of southern Norway into sodalite; into analcite; natrolite and hydronephelite (or ranite) incl. spreustein; into thomsonite; also into potash mica (pinite) and kaolin. See further under these species, and Zs. Kr., **16**, 223–238, 1890. To the alteration into analcite is referred the euthallite of Esmark from the island Sigtesö (cf. Dx., Min., **2**, xxxix, 1874).

*Gieseckite* is shown by Blum to be a pseudomorph after this species. It differs mainly in containing several per cent of water. It occurs in Greenland in six-sided greenish gray prisms of greasy luster, with basal plane and pyramid *p*, having *cp* = 45° nearly; and also at Diana, in Lewis Co., N. Y., with the same angles, for the most part, although the results of measurement vary rather widely (41° to 49°). The crystals of Diana are hexagonal in cleavage; yet the planes of cleavage are often separated by layers of a waxy appearance, without luster or cleavage. According to Des Cloizeaux, the material of the crystals acts on polarized light like a gum or colloid, and is evidently a result of alteration. *Dysyntribite* Shepard from Diana is similar to gieseckite. *Liebenerite*, from the valley of Fleims, in Tyrol, is a similar pseudomorph. Gieseckite was named for Ch. Giesecke who early in the century brought it from Greenland. See further PINITE under the MICA GROUP.

J. Francis Williams has proved (priv. contr.) that elæolite, with orthoclase, may be formed by the alteration of leucite. Crystals of altered leucite from Magnet Cove, Arkansas (mentioned on p. 343), gave the results under 1, while the soluble and insoluble portions (calculated to 100) gave 2 and 3. Of these 2 is elæolite, 3 is orthoclase.

| | $SiO_2$ | $Al_2O_3$[a] | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ | |

[a] Incl. some $Fe_2O_3$.

**Artif.**—Made artificially by Fouqué and Lévy by fusion of a mixture of the elements of the mineral, C. R., **87**, 961, 1878; also by Hautefeuille by fusing a mixture of silica and sodium aluminate with an excess of sodium vanadate; later by Doelter, as already noted. Further, Lemberg has obtained the potash nephelite, $KAlSiO_4$, by digesting elæolite with potassium hydrate, Zs. G. Ges., **37**, 966, 1885, cf. also ib., **28**, 547 *et seq.*, 1876, **40**, 627, 1888. Ch. & G. Friedel have obtained nephelite by heating finely divided muscovite and potash to 500° in the presence of water, Bull. Soc. Min., **13**, 129, 1890.

**Ref.**—[1] Mte. Somma, Min. Russl., **2**, 160, 1854; **9**, 247, 1885; cf. Strüver, who gives *cp* = 43° 50⅔', Albani Mts., Zs. Kr., **1**, 240. 1877. [2] See Scc., Rend. Accad. Napoli, 1842, Pogg., Erg.-Bd., **3**, 478, 1851; Svr., Att. Acc. Torino, **3**, 123, 1867; Klein, Norway, Jb. Min., 532, 1879. [3] Baumh., Zs. Kr., **6**, 209, 1881. [4] Min., **1**, 286, 1862. ## 358. EUCRYPTITE. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **20**, 266, 1880.

Lithionnephelin *Germ.*

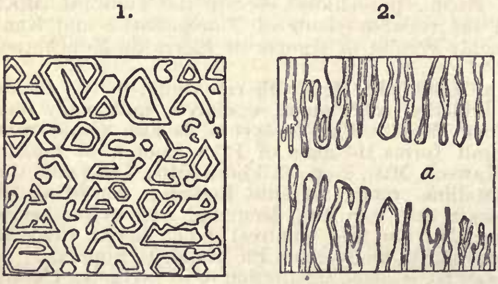

Fig. 1, Section ⊥ fibers; 2, ∥ fibers, showing eucryptite embedded in albite.

Hexagonal. In symmetrically arranged crystals, embedded in albite.

Cleavage: basal. G. = 2·667. Colorless or white. Transparent.

**Comp.**—An orthosilicate of lithium and aluminium, $LiAlSiO_4$ or $Li_2O.Al_2O_3.2SiO_2$ = Silica 47·6, alumina, 40·5, lithia 11·9 = 100.

**Anal.**—S. L. Penfield, l. c.

| $SiO_2$ | $Al_2O_3$ | $Li_2O$ | $K_2O$ |
|---|---|---|---|
| 48·13 | 40·50 | 10·90 | 0·47 = 100 |

An analysis of "β spodumene" (see p. 368) gave: Insoluble portion 67·56, soluble 32·10 = 99·66; the analysis of the soluble portion, reduced to 100, gave the results above. The latter (eucryptite) gelatinizes with hydrochloric acid.

**Obs.**—Eucryptite is known only as forming with albite an apparently homogeneous substance, derived from the alteration of spodumene at Branchville, Conn. The microscope shows the two minerals of which this substance is made up, and chemical analysis serves to separate them.

Named from εὐ, *well*, and κρυπτός, *concealed.*

**359. KALIOPHILITE.** *Mierisch*, Min. Mitth., **8**, 160, 1886. Facellite *E. Scacchi*, Rend. Acc. Napoli, Dec., 1888. Phacellite. Phacelite *Hintze*, Min., **2**, 96, 1889. Kalinephelin *Germ.*

Hexagonal. In bundles of slender acicular crystals, also in fine threads filling the rock cobweb-like.

Cleavage: basal, perfect. Brittle. H. = 6. G. = 2·493 Scc.; 2·602 M. Luster silky, brilliant. Colorless. Transparent. Optically uniaxial, negative.

**Comp.**—$KAlSiO_4$ or $K_2O.Al_2O_3.2SiO_2$ = Silica 38·0, alumina 32·3, potash 29·7 = 100.

**Anal.**—1, Mierisch. 2, Bischoff, ibid. 3, E. Scc., l. c.

| | $SiO_2$ | $Al_2O_3$ | CaO | $K_2O$ | $Na_2O$ | |
|---|---|---|---|---|---|---|
| 1. | $\frac{2}{2}$ 37·45 | 32·43 | 2·18 | 27·20 | 2·26 | = 101·52 |
| 2. | 37·05 | 29·47 | 1·01 | 28·49[a] | 1·10[a] | $Fe_2O_3$ 2·73, ign. 1·08 = 100·93 |
| 3. | 37·73 | 33·09 | — | 29·30 | 0·37 | = 100·49 |

[a] Determined separately.

**Pyr.**—Decomposed by hydrochloric acid with gelatinization.

**Obs.**—Described by Mierisch (*kaliophilite*) as occurring in ejected masses from Mte. Somma; by Scacchi (*facellite*) as occurring in a rock consisting of augite with more or less mica, less often in a gray granular calcite associated with dark colored augite and yellow melilite. The needles are often coated with a grayish incrustation of calcium carbonate.

There can be no question as to the identity of these two minerals, although some authors have failed to recognize it.

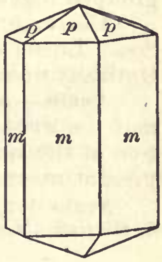
Named from *kalium*, and *φίλος*, *friend*, in allusion to the potash present, it being essentially a potash nephelite. Phacelite is from *φάκελος* (or *φάκελλος*), a *bundle*.

**Artif.**—A crystalline potash nephelite has been formed by Lemberg by digesting elæolite with potassium hydrate as noted on p. 426.

---

**360. CANCRINITE.** *G. Rose*, Pogg., **47**, 379, 1839.

Hexagonal. Axis $\dot{c}$ = 0·4224; 0001 ∧ 10$\bar{1}$1 = 26°, and *mp* = *64°, *pp'* = 25° 58' Törnebohm[1]. Rarely in prismatic crystals with a low terminal pyramid. Usually massive.



Cleavage: prismatic (*m*) perfect; *a* less so. H. = 5–6. G. = 2·42–2·5; 2·404 Sæmann & Pisani. Color white, gray, yellow, green, blue, reddish. Streak uncolored. Luster sub-vitreous, or a little pearly or greasy. Transparent to translucent. Optically uniaxial, negative, Btd.

**Comp.**—$H_6Na_6Ca(NaCO_3)_2Al_8(SiO_4)_9$ or $3H_2O.4Na_2O.CaO.4Al_2O_3.9SiO_2.2CO_2$ = Silica 38·7, carbon dioxide 6·3, alumina 29·3, lime 4·0, soda 17·8, water 3·9 = 100.

The formula is often written as if the compound consisted of a silicate of sodium and aluminium analogous to nephelite, with calcium carbonate and water. This, however, has been repeatedly shown to be an incorrect view of the chemical constitution; the $CO_2$ must be present as a radical, probably ($NaCO_3$). The early view that cancrinite was simply an altered form of nephelite has long since been disproved.

**Anal.**—1, Rauff, Zs. Kr., **2**, 456, 1878. 2, A. Koch, Jb. Min., Beil., **1**, 144, 1880. 3, Lemberg, Zs. G. Ges., **39**, 598, 1887, also **35**, 594, 1883. 4, Lindström, G. För. Förh., **6**, 549, 1883. 5, 6, 7, F W. Clarke (and Riggs), Am. J. Sc., **31**, 263, 1886. Also 5th Ed., p. 329.

**Pyr., etc.**—In the closed tube gives water. B.B. loses color, and fuses (F. = 2) with intumescence to a white blebby glass, the very easy fusibility distinguishing it readily from nephelite. Effervesces with hydrochloric acid, and forms a jelly on heating, but not before.

**Obs.**—Found at Miask in the Ural; of citron-yellow color at the Mariinsk graphite mine in the Tunkinsk Mts., 400 versts west of Irkutsk, in a coarse granite, with zircon, calcite, and magnetite; at Barkevig and other points in the Langesund fiord, Norway, whitish and pale yellowish, wax-yellow, less often blue, associated with blue sodalite and "bergmannite;" at Ditró in Transylvania, pale flesh-red, in the rock called *ditroyte*, consisting of orthoclase, elæolite, and sodalite.

At Litchfield and West Gardiner, Me., with elæolite and blue sodalite.

Named after Count Cancrin, Russian Minister of Finance.

**Alt.**—Occurs altered (but sparingly, Bgr.) to natrolite (*bergmannite*) or spreustein. Cf. Sæmann and Pisani, Ann. Ch. Phys., **67**, 350, 1863.

Lemberg describes the transformation of cancrinite by boiling with a $CaCl_2$ solution at 180°–190° into a "Kalk-cancrinit;" also by action of $K_2CO_3$ into $KAlSiO_4$; while that was changed by $Na_2CO_3$ to a cancrinite; also cancrinite to a hydrated Mg-Al silicate by the action of $MgSO_4$. See further Zs. G. Ges., **35**, 593, 1883, **39**, 598, 1887, **40**, 627, 1888.

**Ref.**—[1] Elfdalen, G. För. Förh., **6**, 390, 1883. Brögger measured on crystals (fig. above) from the Langesund fiord, $mp = 60°$ to $66°$, the best mean value being 63° 1′; this gives $\dot{c} = 0·4409$.

KALK-CANCRINITE *Lemberg*, Zs. G. Ges., **28**, 582, 1876.

Granular massive. H. = 6. Cleavage none. Colorless. Doubly-refracting. Analysis:

$SiO_2$ 39·82 $Al_2O_3$ 33·54 CaO 17·63 $Na_2O$ 0·76 $CaCO_3$ 9·09 = 100·84

Gives off no $CO_2$ in the cold with concentrated hydrochloric acid only on heating, when the silica separates as a jelly.

From Vesuvius, associated with calcite, wollastonite, and brown garnet. On the lime-cancrinite formed by digesting cancrinite with a hot solution of $CaCl_2$, see Lemberg above, and Zs. G. Ges., **35**, 594, 1883.

**361. MICROSOMMITE.** *Scacchi*, Rend. Accad. Napoli, Oct., 1872, and Zs. G. Ges., **24**, 506, 1872. Mikrosommit.

Hexagonal. Axis $\dot{c} = 0·41834$; $0001 \wedge 10\bar{1}1 = {}^*25° \, 47'$ Scacchi[1].

**Forms:** *c* (0001, *O*): *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2), *n* ($21\bar{3}0$, *i*-$\frac{3}{2}$); *p* ($10\bar{1}1$, 1). Angles: $pp' = 25° \, 7'$, $mp = 64° \, 13'$, $ap = 67° \, 52'$.

In minute prismatic crystals, faces striated vertically; *c* dull. Crystals often grouped together.

Cleavage: *m* perfect; *c* less distinct. H. = 6. G. = 2·444 Rauff; 2·42–2·53 Scc. Luster on *m* silky, brilliant; otherwise vitreous. Colorless. Transparent. Optically uniaxial, positive, Btd.

**Comp.**—According to Rauff's analyses, nearly $(Na,K)_{10}Ca_4Al_{12}Si_{12}O_{52}SCl_4$; this may be written $4(Na,K)CaAl_3(SiO_4)_3.4(Na,K)Cl.(Na,K)SO_4$. The true constitution of the mineral is, however, complex and uncertain; carbon dioxide is also present in small amount.

**Anal.**—1, 2, Scacchi, Rend. Acc. Napoli, April, 1876. 3, 4, Rauff, Zs. Kr., **2**, 468, 1878. 5, Mierisch, Min. Mitth., **8**, 161, 1886.

[a] $Fe_2O_3$ in small amount

Deduct oxygen equivalent of the chlorine, viz. in 1, 1·51 p. c., 2, 1·76, 3, 1·60, 4, 1·56 p. c.

**Pyr., etc.**—B.B. fusible with difficulty. In hydrochloric acid decomposed with separation of gelatinous silica.

**Obs.**—Occurs at Vesuvius on Monte Somma in ejected masses, and in the leucitic lava.

**Ref.**—[1] Scc., l. c. Cf. Rath, Pogg., Erg., **6**, 372, 1873; Rauff, l. c.

DAVYNE. Davina *Monticelli* and *Covelli*, Min. Vesuv., 1825.

Hexagonal; in crystals resembling nephelite. Cleavage: basal and prismatic, perfect. Fracture conchoidal. H. = 5·5. G. = 2·40 Haid., 2·43 Breith. Luster vitreous to pearly on cleavage. Colorless to white. Translucent. Optically uniaxial, positive, Btd. Indices: $\omega_y = 1·515$, $\epsilon_y = 1·519$, Dx. (see Btd., Bull. Soc. Min., **5**, 141, 1882). Composition near cancrinite. Anal.—Rg., Pogg., **109**, 579, 1860.

| | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | $CO_2$ | $H_2O$ |

| 3. | 36·96 | 28·31 | 9·39 | *undet* | | 6·04 | ·· |

Fuses with intumescence to a clear slightly blebby glass coloring the flame yellow (soda). From Monte Somma with nephelite, etc. Much so-called davyne is only microsommite; the existence of a cancrinite-like mineral, however, can hardly be doubted. Groth includes davyne and microsommite under sommite, Tab. Ueb., 123, 1889.

CAVOLINITE. *Monticelli* and *Covelli*, Min. Vesuv., 1825. From Monte Somma with davyne, etc. Generally assumed to be identical with nephelite, but perhaps rather belonging to microsommite (Scc.) like which it is optically positive (Btd.), Bull. Soc. Min., 5, 141, 1882.

---

## 2. Sodalite Group. Isometric.

| | | |
|---|---|---|
| **362.** | **Sodalite** | $Na_4(AlCl)Al_2(SiO_4)_3$ |
| **363.** | **Haüynite** | $(Na_2,Ca)_2(NaSO_4.Al)Al_2(SiO_4)_3$ |
| **364.** | **Noselite** | $Na_4(NaSO_4.Al)Al_2(SiO_4)_3$ |
| **365.** | **Lazurite** | $Na_4(NaS_3.Al)Al_2(SiO_4)_3$ |

The formulas are written above in the form suggested by Brögger, who shows that this group and the one following may be included with the garnets in a broad group characterized by isometric crystallization and a close resemblance in composition. See further under the GARNET GROUP proper, p. 437.

---

**362. SODALITE.** Sodalite (fr. Greenland) *Thomson*, R. Soc. Ed. Tr., 6, 387, read Nov. 5, 1810; Phil. Mag., 36, 471, 1810. Glaukolith *Weibye*, Karst. Arch., 22, 532, 1848.

Isometric. Observed forms[1]:

*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1)[2]; *n* (211, 2-2), *μ* (411, 4-4)[2].

Twins: tw. pl. *o*, forming hexagonal prisms by elongation in the direction of an octahedral axis. Common form the dodecahedron. Also massive, in embedded grains; in concentric nodules resembling chalcedony, formed from elæolite.

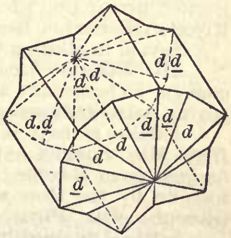
Cleavage: dodecahedral, more or less distinct. Fracture conchoidal to uneven. Brittle. H. = 5·5–6. G. = 2·14–2·30. Luster vitreous, sometimes inclining to greasy. Color gray, greenish, yellowish, white; sometimes blue, lavender-blue, light red. Transparent to translucent. Streak uncolored. Refractive indices:

Bolivia $n_r$ = 1·4796 Li $n_y$ = 1·4827 Na $n_{gr}$ = 1·4855 Tl $n_v$ = 1·496 violet, Feussner[3].

Brögger[4] finds the etching-figures triangular in form. and symmetrical to a dodecahedral face normal to the face etched, but not symmetrical to the cubic planes normal to this. From this it is concluded that the crystals are tetrahedral and twinned with the cube as tw. plane

**Var.**—1. Ordinary, varying in color from bright azure blue to gray, yellow or greenish. Crystals not common; usually in dodecahedrons.

2. In reniform or nodular forms with concentric structure, often resembling chalcedony. Fracture conchoidal to even. Luster dull. Color blue to gray or green. Formed from elæolite in the elæolite-syenite of southern Norway. This mineral is called *glaukolith* by Weibye, Jb. Min., 775, 1849. Karst. Arch., 22, 532, 1848. This name was earlier given to a blue mineral from the L. Baikal region, which is a massive kind of scapolite (see p. 469). A so-called "glaucolite" from L. Baikal, investigated by Brögger and Bäckström, proved to be sodalite, anal. 4.



Mte. Somma, Sbk.

**Comp.**—$Na_4(AlCl)Al_2Si_3O_{12}$ = Silica 37·6, alumina 31·6, soda 25·6, chlorine 7·3 = 101·7, deduct (O = 2Cl) 1·7 = 100. Potassium replaces a small part of the sodium.

The above is the formula of Brögger, which not only agrees well with the best analyses, but also brings out the relation to the garnet group, cf. p. 437.

The formula may also be written $3NaAlSiO_4 + NaCl$.

**Anal.**—1, 2, Rg., Pogg., **109**, 574, 1860. 3, Hofmann, ib., **47**, 377, 1839. 4, Brögger and Bäckström. Zs. Kr., **18**, 223, 1890. 5, Bäckström, Zs Kr., **16**, 180, 1890. 6, Lorenzen, Min. Mag., **5**, 58, 1882. 7, Fleischer, quoted by Rath, Ber. nied. Ges., March 13, 1876. 8, Bamberger, Zs. Kr., **5**, 583, 1881. 9, F. W. Clarke, Am. J. Sc., **31**, 264, 1886. 10, 11, Harrington, Trans. Roy. Soc., Canada, **4** (3), 81, 1886. 12, Ch. and G. Friedel, Bull. Soc. Min., **13**, 185, 1890. See also 5th Ed., p. 330.

| 10. Montreal | 2·20 | 37·52 | 31·38 | 0·35 | 25·16 | 0·78 | 6·91 $Fe_2O_3$. MgO *tr.* = [102·10 |
| 11. Ice R., Rocky Mts. | 2·293 | 37·50 | 31·82 | — | 25·55 | 0·27 | 7·12 = 102·26 |
| 12. *Artificial* | 2·32 | 36·65 | 32·24 | — | 25·70 | 0·67 | 6·32 = 101·58 |

From the above analyses the oxygen-equivalent of the chlorine is to be deducted.

A green sodalite from Vesuvius gave Lemberg (Zs. G. Ges., **28**, 550, 1876) 8·98 $Na_2SO_4$ possibly from admixture of haüynite.

**Pyr., etc.**—In the closed tube the blue varieties become white and opaque. B.B. fuses with intumescence, at 3·5–4, to a colorless glass. Decomposed by hydrochloric acid, with separation of gelatinous silica.

**Obs.**—Occurs most commonly in syenite, also basalt and other volcanic rocks often associated with nephelite (or elæolite), cancrinite, and eudialyte. With sanidine it forms a *sodalite-trachyte* at Scarrupata in Ischia, in which also occur augite, titanite, and magnetite in crystals. In Sicily, Val di Noto, with nephelite and analcite. At Vesuvius, in bombs on Monte Somma (cf. Mierisch, Min. Mitth., **8**, 163, 1886), in white, translucent, dodecahedral crystals, with haüynite, sanidine, pyroxene, mica, and rarely in green dodecahedrons, with cubic planes, in limestone along with vesuvianite and nephelite; massive and of a gray color at the Kaiserstuhl; also near Lake Laach. At Ditró, Transylvania, in an elæolite-syenite with cancrinite, etc. In the foyayte of southern Portugal. At Miask, in the Ilmen Mts., blue in the granite-like rock called *miascyte*, with elæolite and feldspar: Sedlovaty, in the White Sea, with eudialyte; in the augite-syenite of the Langesund-fiord region in Norway, in the islands Låven, Lövö, Lille Arö, Sigtesö, etc., of a lavender-blue color, with elæolite, ægirite, wöhlerite, and rarely eudialyte, but for the most part altered to spreustein (p. 602); also in the same region formed as a later product from the alteration of elæolite, in compact form, sometimes resembling chalcedony (anal. 5). Further in West Greenland in sodalite-syenite on both sides of the fiords Tunugdliarfik and Kangerdluarsuk, along with a greenish feldspar, arfvedsonite, and eudialyte: the crystals are often dodecahedrons and inclose microscopic crystals of arfvedsonite, thus gaining a greenish color. Found among the ruins of Tiahuanaco, Bolivia, exact locality unknown.

A blue variety occurs at Litchfield and West Gardiner, Me., massive, with distinct cleavage, associated with elæolite, zircon, and cancrinite, and the alteration-product, hydronephelite; in a vein in syenite, at Salem, Mass., violet to azure blue, with elæolite, orthoclase, biotite, and zircon. In the "theralite" of the Crazy Mts., Montana. Occurs also in the elæolite-syenite of Brome, Brome Co., of Montreal and Belœil, province of Quebec; in fine large masses on Ice River, a tributary of Beaver-Foot, in the Rocky Mts. near Kicking Horse Pass, British Columbia.

Named in allusion to its containing soda.

**Alt.**—Sodalite occurs altered to kaolin, like the feldspars, and also in conditions of partial change. Thomsonite and hydronephelite (a soda-thomsonite) are alteration products; also muscovite, natrolite (spreustein, wh. see), and diaspore, see Bgr., Zs. Kr., **16**, 184, 1890.

Sodalite is itself in part derived from nephelite (elæolite) and pseudomorphs after nephelite from Mte. Somma have been described. Also occurs in Norway in compact massive forms derived from elæolite. Further Mügge has shown that nephelite can be transformed into sodalite by the slow action of fused sodium chloride, with the addition of vaporized NaCl (Rosenb., Mikr. Phys., 284, 1886); cf. also Lemberg's experiments, Zs. G. Ges., 1883, 1885, 1888.

**Artif.**—Obtained by Ch. and G. Friedel by heating to 500° muscovite with soda in the proportions to form nephelite, with the addition of sodium chloride. The crystals, mixed also with crystals of nephelite, were rhombic dodecahedrons with cubic faces, in part twins with tw. pl. *o*, often elongated in the direction of an octahedral axis. The composition of these crystals is given in anal. 12. By heating with water 6 grams of $SiO_2$, 5·15 $Al_2O_3$, 3·6 $Na_2O$, and 1·95 NaCl, radiated globules were obtained, inferred to have the composition of sodalite. Bull. Soc. Min., **13**, 183, 1890.

**Ref.**—[1] Mlr., Min., 398, 1852. [2] Klein, Langesund fiord, Jb. Min., 534, 1879. [3] Zs. Kr., **5**, 581, 1881, Vesuvius crystals gave identical results. [4] Bgr., Zs. Kr., **18**, 215, 1890.

**363. HAÜYNITE** or HAÜYNE. Latialite (fr. the Campagna, ancient Latium) *Gismondi*, in Mem. read in 1803, before the Accad. de Lincei at Rome, but unpublished. Haüyne *Bruun-Neergard*, Gehlen J., **4**, 417, 1807, J. Mines, **21**, 365, 1807. Berzeline, *L. A. Necker*, Bibl. Univ., **46**, 52, 1831, Regne Min. Paris, 1835; *Rath*, Zs. G. Ges., **18**, 546, 1866 = Marialite *Ryllo* = Gismondina ottaedrica *Med. Spada.* Auina, Lazialite *Ital.*

Isometric. Observed forms[1]:

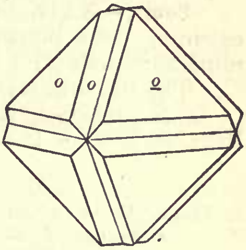
*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1); *e* (210, *i*-2; *n* (211, 2-2).

Twins: tw. pl. *e*; contact-twins, also polysynthetic; penetration-twins. Sometimes in dodecahedrons, octahedrons, etc.; but commonly in rounded grains, often looking like crystals with fused surfaces.

Cleavage: dodecahedral, rather distinct. Fracture flat conchoidal to uneven. Brittle. H. = 5·5–6. G. = 2·4–2·5. Luster vitreous, to somewhat greasy. Color bright blue, sky-blue, greenish blue; asparagus-green, red, yellow. Streak slightly bluish to colorless. Subtransparent to translucent; often enclosing symmetrically arranged inclusions. Refractive index, Niedermendig[2], $n_{y}$ = 1·4961.

**Comp.**—$Na_2Ca(NaSO_4.Al)Al_2Si_3O_{12}$. This is analogous to the garnet formula (Brögger) where the place of the $R_3$ is taken by $Na_2$,Ca and the group $Na-O-SO_2-O-Al$. The percentage composition is: Silica 32·0, sulphur trioxide 14·2, alumina 27·2, lime 10·0, soda 16·6 = 100. The ratio of $Na_2$ : Ca also varies from 3 : 2; potassium may be present in small amount.

1.



Albano, Rath.

The formula may also be written $2(Na_2,Ca)Al_2(SiO_4)_2 + (Na_2,Ca)SO_4$.

**Anal.**—1, Rg., Pogg., **109**, 577, 1860. 2, Rath, Zs. G. Ges., **18**, 547, 1866. 3, 4, Ricciardi [Gazz. Ch., **17**, 216, 1857], Zs. Kr., **14**, 519. 5, Rath, Zs. G. *Berzeline* of Necker is the white variety from near Albano according to Rath (anal. 2, and fig. 1).

**Pyr., etc.**—In the closed tube retains its color. B.B. in the forceps fuses at 4·5 to a white glass. Fused with soda on charcoal affords a sulphide, which blackens silver. Decomposed by hydrochloric acid with separation of gelatinous silica.

**Obs.**—Common in certain igneous rocks, thus in haüynophyre, in phonolyte, tephryte; very commonly associated with nephelite and leucite. Occurs in the Vesuvian lavas, on Mte. Somma; at Melfi, on Mt. Vultur, Naples, of black, green, blue, red, and brown colors, and also white, and sometimes red inside and blue outside; in the lavas of the Campagna, Rome, and also in the peperino of Marino and Lariccia near Albano, sky-blue, bluish green, and sometimes opaline, also white (*berzeline*); at Niedermendig, Mayen, Olbrück, in the Eifel; the phonolytes of Hohentwiel; at Mt. Dore in Puy-de-Dôme; at St. Michael's, Azores; the Canary islands; the Cape Verde islands. In the theralyte of the Crazy Mts., Montana. Also in the lapis-lazuli of Siberia (p. 433).

Named in honor of the Abbé Haüy (1743–1822).

**Ref.**—[1] Cf. Mlr., Min., 399, 1852; Dx., Min., 524, 1862; Rath, l. c.; Hbg., Min. Not., **8**, 43, 1868; Svr., Zs. Kr., **1**, 235, 1877; in Dana, Min., 5th Ed., 332, 1868, the planes 311, 331 are added, source unknown to author. [2] Tschihatscheff, quoted by Rosenb., Mikr. Phys., 286, 1885.

**Pyr., etc.**—B B. like haüynite. Gelatinizes in acids, yielding no hydrogen sulphide.

**Obs.**—From near Andernach on the Rhine; at the Laacher See, in loose blocks consisting largely of sanidine or glassy feldspar, with mica, magnetite, and occasionally zircon, occupying cavities in the feldspar, in small grains or crystals; also found at Rieden and Volkersfeld in a leucite rock. In the phonolytes of the Hegau at Hohentwiel; also of the Kaiserstuhl; the Canary and the Cape Verde islands, and at other localities.

Named after K. W. Nose of Brunswick (1753–1835).

**Ref.**—[1] Hubbard, Min. Mitth., **8** 362, 1887.

ITTNERITE *Gmelin*, Schw. J., **36**, 74, 1822. Skolopsite *Kbl.*, Gel. Anzeig., **28**, 638, 1849. Alteration products of haüynite and noselite as shown by Rammelsberg, Ber. Ak. Berlin, 172, 1864, Min. Ch., 459, 1875; also confirmed by Van Werweke, Jb. Min., **2**, 264, 1880. Cf. also Fischer, Mikr. Min., 36, 1869, Lemberg, Zs. G. Ges., **28**, 610, 1876. For analyses, see 5th Ed., p. 333.

Ittnerite contains 10 to 12 p. c. of water, and scolopsite varies in the water from none to 10 p. c. Ittnerite occurs in translucent dodecahedrons or granular massive, with H. = 5·5; G. = 2·37–2·40; color dark bluish or ash-gray to smoky gray; luster resinous. It comes from the Kaiserstuhl near Freiburg, Baden, at Sasbach and Endingen.

Scolopsite occurs granular massive; H. = 5; G. = 2·53, color grayish white to pale reddish gray, and is also from the Kaiserstuhl, and occurs in the same rock with ittnerite (Fischer, Ber. Ges. Freiburg, 1862). Scolopsite was named from *σκόλοψ, a splinter,* from its splintery fracture.

**365. LAZURITE.** Lasurit *Brögger*, Zs. Kr., **18, 231, 1890.**

LAPIS-LAZULI. *Σαπφειρος Theophr.* Sapphiros *Plin.*, **37**, 39. Sapphirus *Agric.*, Foss., 288, 1546. Cyaneus, Lapis Lazuli (Lapis Azul *Arab.*, unde nomen Asuri, aut Lazuli), *B. de Boot*, Lap., 273, 1636. Lapis-Lazuli, Lazur-Sten, Jaspis colore cœruleo cuprifer, *Wall.*, Min., 97, 1747. Lapis-Lazuli, ou Pierre d'Azur, *Fr. Trl.* Wall., **1**, 186, 1753. Zeolites Bloa (= Blue Zeolite), Lapis Lazuli, *Cronst.*, 100, 1758. Zeolithus cæruleus *v. Born.*, Lithoph., **1**, 46, 1772. Lasurstein *Germ.* Native Ultramarine. Outremer *Fr.*

Isometric. In cubes and more commonly dodecahedrons. Also massive, compact.

Cleavage: dodecahedral, imperfect. Fracture uneven. H. = 5–5·5. G. = 2·38–2·45. Luster vitreous. Color rich Berlin-blue or azure-blue, violet-blue greenish blue. Translucent.

**Comp.**—Essentially $Na_4(NaS_3.Al)Al_2Si_3O_{12}$ as shown by Brögger, but containing also in molecular combination $(Na_2,Ca)_2(NaSO_4.Al)Al_2Si_3O_{12}$ or haüynite (in varying amount), and $Na_4(AlCl)Al_2Si_3O_{12}$ or sodalite. The percentage composition of this ultramarine compound (Bgr.) is as follows: Silica 31·7, ~~alumina~~ 26·9, soda 27·3, sulphur 16·9 = 102·9, or deduct (O = S) 2·9 = 100.

**Anal.**—Brögger and Bäckström, Zs. Kr., **16**, 236, 1890.

| | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | $SO_3$ | S | Cl |
|---|---|---|---|---|---|---|---|---|
| Central Asia | 32·52 | 27·61 | 6·47 | 19·45 | 0·28 | 10·46 | 2·71 | 0·47 = 99·57 |

This is interpreted as equivalent to haüynite, ultramarine, and sodalite in the ratio of 77 : 16 : 7. It may also be explained by assuming the presence of $Na_4(NaS_2.Al)Al_2Si_3O_{12}$.

Earlier analyses are the following: 1, Köhler, Rg., Min. Ch., 710, 1860. 2, Schultz, ib. 3, Varrentrapp, Pogg., **49**, 519, 1840. 4, Hauer, Vh. G. Reichs., 86, 1860. 5, Schultz, l. c.

From 1, 6·7 $CaCO_3$, from 2, 32·69 p. c. $CaCO_3,MgCO_3$, and from 5, 28·77 $CaCO_3$ have been deducted.

The heterogeneous character of what had long passed as a simple mineral under the name Lapis-lazuli was shown by Fischer (1869), Zirkel (1873), and more fully by Vogelsang (1873). The latter showed the presence of an isometric, ultramarine mineral, which is generally blue, or violet, sometimes also colorless, and in the last case assumes a blue color on heating. This is intermixed with granular calcite and scapolite (paralogite). Fischer, Mikr. Stud., 36, 1869; Zirkel, Mikr. Besch. Min., 165, 1873; Vogelsang, Med. Akad., Amsterdam, 161, 1873.

It has remained for Brögger and Bäckström to separate the essential part of this mineral mixture (lazurite) and determine its composition, as given above. The ordinary natural lapis lazuli (Lasurstein) is shown to contain lazurite or haüynite (sometimes changed to a zeolite), a diopside free from iron, amphibole (koksharovite), mica (muscovite), calcite, pyrite; also in some varieties in relatively small amount scapolite, plagioclase, orthoclase (microperthite?), apatite, titanite, zircon, and an undetermined mineral optically + and probably uniaxial.

**Pyr., etc.**—Heated in the closed tube gives off some moisture; the variety from Chili glows with a beetle-green light, but the color of the mineral remains blue on cooling. Fuses easily (3) with intumescence to a white glass. Decomposed by hydrochloric acid, with separation of gelatinous silica and evolution of hydrogen sulphide.

**Obs.**—Occurs in Badakshan in the valley of the Kokcha, a branch of the Oxus, a few miles above Firgamu; the quarries are in limestone, and the mineral occurs in three varieties, indigo-blue (nili), light blue (asmani), and green (sabzi). Cf. Ball., Geol. India, III, 528. 1881. Also at the south end of L. Baikal at various points on the rivers Talaya, Malaya-Bystraya, and Sliudianka (see Bull. Soc. Mosc., **30** (2), 518, 1857), where it occurs in a dolomitic limestone in connection with granite. Also reported from other points in Eastern Asia, but uncertain. Further, in Chili in the Andes of Ovalle, near the sources of the Cazadero and Vias, tributaries of the Rio Grande, in a granitic rock. In ejected masses at Monte Somma, rare (Pogg., **138**, 491, 1869), and in limestone inclusions in the peperino of Latium (Svr., Zs. Kr., **1**, 238, 1877). Probably always (Bgr.) a result of contact metamorphism in limestone.

The richly colored varieties of lapis lazuli are highly esteemed for costly vases and ornamental furniture; also employed in the manufacture of mosaics; and when powdered constitutes the rich and durable paint called *ultramarine*. This has been replaced, however, by artificial ultramarine, now an important commercial product.

**Artif.**—The following are typical analyses of artificial ultramarine, quoted in the form given by Brögger and Bäckström. The original references are:

1. Heumann (Hoffmann), Lieb. Ann., **203**, 174, 1880. 2, Id., ib., **194**, 1 *et seq.*, 1878. 3, Szilasi, ib., **251**, 100, 1889.

| | $SiO_2$ | $Al_2O_3$ | $Na_2O$ | S |
|---|---|---|---|---|
| 1. *blue* | 39·3 | 30·7 | 23·1 | 8·4 |
| 2. “ | 40·7 | 24·0 | 23·5 | 13·6 |
| 3. *green* | § 37·30 | 31·07 | 25·34 | 7·24 |

In explaining the composition of the various forms of artificial ultramarine, the following compounds are assumed: $Na_3Al_3Si_3O_{12}$, $Na_2Al_2Si_4O_{12}$, $Na_4(NaS.Al)Al_2Si_3O_{12}$, $Na_4(NaS_2\ Al)$ $Al_2Si_3O_{12}$, $Na_4(NaS_3.Al)Al_2Si_3O_{12}$. The compound causing the blue color in both the natural lazurite and the artificial ultramarine is probably one belonging to the sodalite group, viz., $Na_4(NaS_3.Al)Al_2(SiO_4)_3$.

## 3. Helvite Group. Isometric, tetrahedral.

| | | |
|---|---|---|
| **366.** | **Helvite** | $(Mn,Fe)_2(Mn_2S)Be_3(SiO_4)_3$ |

On the relation of the above species to the GARNET GROUP, see p. 437.

---

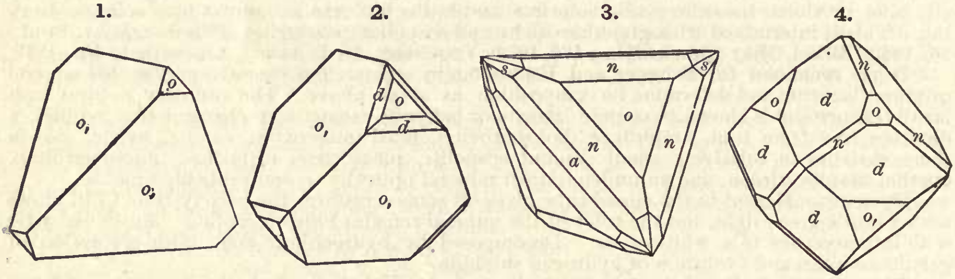
**366. HELVITE.** Ein Fossil w. Aehnlichk. m. d. Granat hat, aber nicht Granat zu seyn scheint, *Mohs*, Null Kab., **1**, 92, 1804. Helvin *Wern.*, 1816, Breith. in Hoffm. Min., **4**, b. 112, 1817. Wern., Letztes Min. Syst., 2, 29, 1817; Tetrahedral Garnet *Mohs*, Char. Syst. Min., 71, 1820, Edinb. Tetraëdrischer Granat *id.*, Grundr., 412, 1824.

Isometric; tetrahedral. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *i*); *o* (111, 1); $o_{,}$ ($\bar{1}$11, – 1); *r* (332, $\frac{3}{2}$); *n* (211, 2-2); *s* (321, 3-$\frac{3}{2}$).

Commonly in tetrahedral crystals, rarely dodecahedral in habit; also in spherical masses.

Cleavage: octahedral in traces. Fracture uneven to conchoidal. Brittle. H. = 6–6·5. G. = 3·16–3·36; 3·216, Breith. Luster vitreous, inclining to resinous. Color honey-yellow, inclining to yellowish brown, and siskin-green, reddish brown. Streak uncolored. Subtransparent. Refractive index $n = 1·739$ Lévy-Lcx.[2] Pyroelectric[3].



1. 2. 3. 4.

Figs. 1–4. Langesund fiord, Norway, Brögger.

**Comp.**—$(Be,Mn,Fe)_7Si_3O_{12}S$. This may be written $(Mn,Fe)_2(Mn_2S)Be_3Si_3O_{12}$ as suggested by Brögger[4], analogous to the Garnet Group, the bivalent group –Mn–S–Mn (also assumed by Groth) taking the place of a bivalent element, R, and 3Be corresponding to 2Al, cf. p. 437. Assuming Mn present alone, the percentage composition is: Silica 32·5, glucina 13·6, manganese protoxide 51·0, sulphur 5·8 = 102·9, deduct (O = S) 2·9 = 100.

Composition also written $3(Be,Mn,Fe)_2SiO_4.(Mn,Fe)S$.

**Anal.**—1, Gmelin, Pogg., **3**, 53, 1825, corrected by Rg., Min. Ch., 701, 1860. 2, Rg., ibid., Pogg., **93**, 453, 1854. 3, Bäckström, Zs. Kr., **16**, 176, 1890. 4, 5, Teich, Min. [a] $Fe_2O_3$.

From anals. 3, 4, 5, the oxygen-equivalent of the sulphur is to be deducted.

**Pyr., etc.**—Fuses at 3 in R.F. with intumescence to a yellowish brown opaque bead, becoming darker in R.F. With the fluxes gives the manganese reaction. Decomposed by hydrochloric acid, with evolution of hydrogen sulphide and separation of gelatinous silica.

**Obs.**—Occurs in gneiss at Schwarzenberg in Saxony, associated with garnet, quartz, fluorite, and calcite; at Breitenbrunn, Saxony; at Kapnik, Hungary, on quartz and rhodochrosite; at Hortekulle near Modum, Norway, also in the pegmatyte veins of the augite-syenite of the Langesund fiord, on the islands Sigesö, Stokö, Ovre-Arö, associated with ægirite, elæolite, etc. (Bgr., l. c.). In the Ilmen Mts. near Miask in pegmatyte, large spherical masses with topaz, phenacite, monazite, pyrochlore, etc.; also at Lupikko, Finland, with magnetite, fluorite, the crystals sometimes 1½ inches through.

In the U. S., in cracks in spessartite at the mica mines near Amelia Court House, Amelia Co., Va., associated with monazite, microlite, allanite, etc.

Named by Werner, in allusion to its yellow color, from ἥλιος, *the sun.*

**Ref.**—[1] Eremeyev, Finland, Min. Russl., **5**, 320, 1866; Zs. Kr., **15**, 552, 1889; Bgr., Zs. Kr., **16**, 173, 1890. [2] Min. Roches, 222, 1888. [3] J. & P. Curie, C. Sc., **14**, 272, 1852, also 5th Ed., 1868.

ACHTARAGDITE *Russian*, prior to 1847, Glocker's Syn., 305, 1847. Achtarandit *Breith.*, B. H. Ztg., **12**, 370, 1853. Achtaryndit *Auerbach*, Vh. Min. Ges., **3**, 113, 1868.

Isometric; tetrahedral, but probably pseudomorphous. Form a hemi-trisoctahedron, *n* (211), occasionally penetration-twins with parallel axes, like f. 2, p. 436. Crystals sometimes 2 mm. or more in diameter, often having a shining crust but within earthy, adhering to the tongue, and giving a clay-like odor. Soft, soiling the fingers. G. = 2·32 Hermann. Luster dull. Color ash-gray, within white. Opaque.

Anal.—1, Hermann, Bull. Soc. Mosc., **40** (2), 481, 1867. 2, 3, W. v. Beck, Kk., Min. Russl., **5**, 327, 1866.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CaO | MgO | $H_2O$ | $CO_2$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 2·32 | 28·27 | 13·06 | 14·07 | 0·42 | 14·41 | 20·07 | 8·64 | 1·00 | = 99·94 |
| 2. | | 39·25 | 11·11 | 17·09 | — | 12·54 | 3·60 | 10·09 | — | = 93·68 |
| 3. | | 40·10 | 12·36 | *undet.* | | 11·27 | *undet.* | 12·27 | | |

Occurs on the Achtaragda (or Achtarynda), a tributary of the Vilui River in Siberia, with vesuvianite and grossular garnet. These crystals are obviously pseudomorphs and perhaps after helvite, as suggested by Breithaupt. Cf. also Rose, Reis. Ural., **1**, 48, 1837, who referred them to grossularite; Kk., Min. Russl., **5**, 324, 1866. Prendel regards them as more probably pseudomorphous after boracite, since a reaction for boron was obtained from the crystals and the steatite-like substance resembles a common alteration product of boracite (Zs. Kr., **17**, 94, 1889). It is to be remembered, however, that the occurrence of boracite is extremely limited.

### 367. DANALITE. *J. P. Cooke*, Am. J. Sc., 42, 73, 1866.

Isometric. In octahedrons; also with dodecahedral faces, striated longitudinally.

Cleavage not observed. Fracture subconchoidal to uneven. Brittle. H. = 5·5–6. G. = 3·427. Luster vitreo-resinous. Color flesh-red to gray. Streak similar, but lighter. Translucent.

**Comp.**—$(Be,Fe,Zn,Mn)_7Si_3O_{12}S$, which may be written as suggested by Brögger. $(Fe,Zn,Mn)_2((Zn,Fe)_2S)Be_3Si_3O_{12}$, cf. helvite, p. 434.

**Anal.**—J. P. Cooke, l. c.

[a] With $Al_2O_3$.

**Pyr., etc.**—B.B. fuses readily on the edges to a black enamel. With soda on charcoal gives a slight coating of zinc oxide. Perfectly decomposed by hydrochloric acid, with evolution of hydrogen sulphide and separation of gelatinous silica.

**Obs.**—Occurs in the Rockport granite, Cape Ann, Mass., small grains being disseminated through this rock; also near Gloucester, Mass.; in both localities associated with a lithia mica, in the latter with green feldspar and fluorite. Also with magnetite and quartz at the iron mine, at Bartlett, N. H. (Wadsworth). In El Paso Co., Colorado, p. 1032.

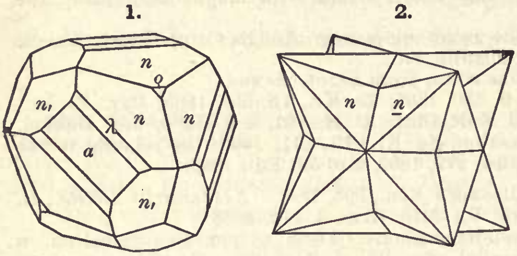
Named after J. D. Dana.

**368. EULYTITE.** Wismuthblende, Eulytin, *Breith.*, Pogg., **9**, 275, 1827; Handb., **2**, 303, 1841. Wismutisches Blende-Erz *Breith.*, Uib., 66, 1830, Char., 239, 1832. Kieselwismuth *Kersten*, Pogg., **27**, 81, 1833. Silicate of Bismuth.

Isometric; tetrahedral. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *I*), *o* (111, 1), *n* (211, 2-2), $n_{,}$ ($2\bar{1}1$, − 2-2), λ (511, 5-5).

Twins: with parallel axes like tetrahedrite, f. 2. Crystals usually minute; common form the hemi-tetragonal trisoctahedron *n* (211); often with rounded edges and in groups; also in spherical forms.



1.
2.

Figs. 1, 2, Schneeberg, Rath.

Cleavage: dodecahedral, very imperfect(?). Fracture uneven. Rather brittle. H. = 4·5. G. = 6·106 Rath. Luster resinous or adamantine. Color dark hair-brown, yellowish gray, grayish white, straw-yellow, colorless. Streak yellowish gray or uncolored. Subtransparent to opaque. Shows anomalous double refraction, and then optically negative, uniaxial, axis ⊥ *o*, Btd.[2]

**Comp.**—$Bi_4Si_3O_{12}$ or $2Bi_2O_3.3SiO_2$ = Silica 16·3, bismuth 83·7 = 100.

**Anal.**—1, 2, Rath, Pogg., **136**, 416, 1869.

**Pyr., etc.**—In a matrass decrepitates and affords a trace of water. B.B. fuses to a dark yellow mass, and gives out inodorous fumes. Fuses and froths on charcoal, staining it yellowish brown, sometimes with a tinge of green. Fuses readily with soda to a button, at first greenish yellow and then reddish yellow, and finally affords metallic bismuth. With salt of phosphorus it fuses to a yellow globule, with a silica skeleton, which becomes colorless on cooling.

**Obs.**—Found with native bismuth near Schneeberg, Saxony, in quartz; also at Johanngeorgenstadt in crystals on quartz.

Named from εὔλυτος, *easily dissolved*, or *fusible*.

**Ref.**—[1] Rath, l. c. [2] Bull. Soc. Min., **4**, 61, 1881; Klein, Jb. Min., **2**, 196 ref., 1882.

**369. ZUNYITE.** *W. F. Hillebrand*, Proc. Col. Soc., **1**, 124, 1884.

Isometric; tetrahedral. In minute tetrahedrons (*o*) with also planes of the negative tetrahedron ($o_{,}$), the cube (*a*), and perhaps those of the dodecahedron (*d*).

Cleavage: *o* and $o_{,}$. Luster vitreous. H. = 7. G. = 2·875. Clear, transparent, but sometimes opaque from inclusions. Optically isotropic.

**Comp.**—A highly basic orthosilicate of aluminium; formula (Groth, Bgr.) $(Al(OH,F,Cl)_2)_6Al_2Si_3O_{12}$, and hence analogous to the garnet group, where the bivalent element, $R_3$, of the latter is replaced by the univalent radicals $Al(OH)_2$, $AlF_2$, $AlCl_2$. Hillebrand deduced the empirical formula $H_{18}Al_{15}Si_6(O,F,Cl)_{45}$.

**Anal.**—Hillebrand, l. c., mean of several partial analyses.

| $SiO_2$ | $Al_2O_3$ | $Na_2O$ | $K_2O$ | $Li_2O$ | $H_2O$ | F | Cl | |
|---|---|---|---|---|---|---|---|---|
| 24·33 | 57·88 | 0·24 | 0·10 | *tr.* | 10·89 | 5·61 | 2·91 | $Fe_2O_3$ 0·20, $P_2O_5$ 0·60 = 102·76[a] |

[a] Deduct 3·02 (O = F,Cl) = 99·74.

**Pyr.**—B.B. infusible, but becomes opaque and porcelain-like. Heated in a closed tube yields acid water. Not attacked by acids.

**Obs.**—Occurs at the Zuñi mine, Anvil Mountain, near Silverton, San Juan Co., Colorado. It is intimately mixed with the sulphide of arsenic and lead, guitermanite (p. 131) and pyrite; also embedded in a white earthy material consisting in part of lead sulphate, and derived from the alteration of the associated ores.

## 4. Garnet Group. Isometric, holohedral.

$$\overset{\text{II}}{R}_3\overset{\text{III}}{R}_2(SiO_4)_3 \text{ or } 3RO.R_2O_3.3SiO_2.$$

$$\overset{\text{II}}{R} = Ca,Mg,\overset{\text{II}}{Fe},\overset{\text{II}}{Mn}. \qquad \overset{\text{III}}{R} = Al,\overset{\text{III}}{Fe}(\overset{\text{III}}{Mn})Cr\overset{\text{III}}{Ti}.$$

Closely related to the GARNET GROUP proper are the species of the Sodalite and Helvite Groups (p. 429, p. 434). All are characterized by isometric crystallization, and all are orthosilicates, and as developed by Brögger with similar chemical structure. Thus the formula of the Garnet Group is $\overset{\text{II}}{R}_3\overset{\text{III}}{R}_2(SiO_4)_3$; to this Sodalite conforms if written $Na_4(AlCl)Al_2(SiO_4)_3$, where $Na_4$ and the bivalent radical AlCl are equivalent to $R_3$ and similarly for Noselite (Haüynite) if the presence of the bivalent group $NaSO_4$–Al is assumed.

In the Helvite Group, which is characterized by the tetrahedral character of the species (perhaps true also of the Sodalites), the chemical relation is less close, but probably exists as exhibited by writing the formula of Helvite $(Mn,Fe)(Mn_2S)Be_3(SiO_4)_3$ where the bivalent group –S–Mn–S– enters, and 3Be may be regarded as taking the place of 2Al. For a further discussion of the subject, with exhibition of structural formulas, etc., see Brögger, Zs. Kr., **16**, 176, 181, 1890, and Brögger and Bäckström, ibid., **18**, 209–276, 1890.

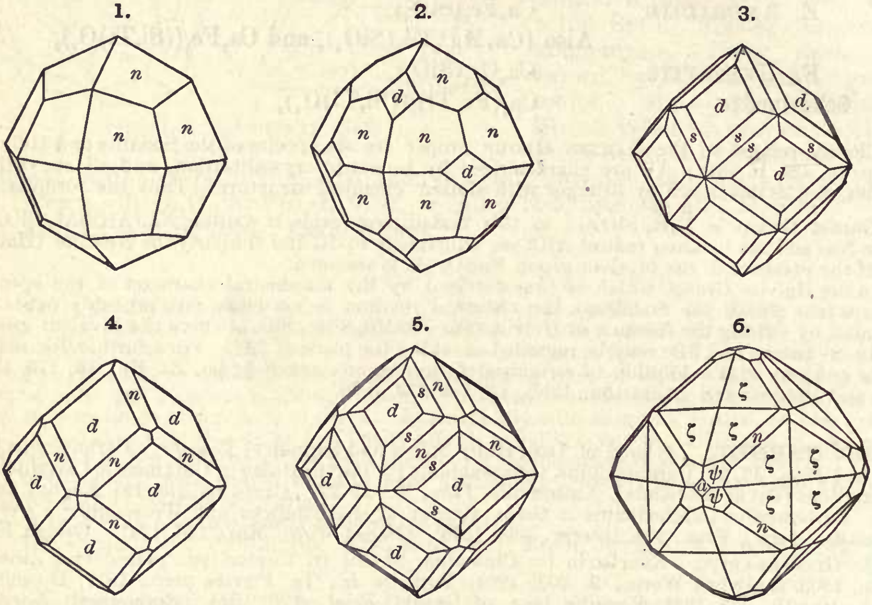
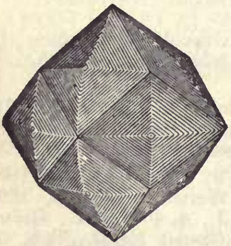


Figs. 1–5, Common forms. 6, Mill Rock, New Haven.

Twins: tw. pl. *e* (210)[12]. The dodecahedron and tetragonal trisoctahedron, (*n*, 211, f. 1), the most common simple forms; also these in combination, f. 2, 4; or with also the hexoctahedron *s* (321) as in f. 3, 5. Faces *d* often striated ∥ longer diagonal; sometimes built up of successive plates (f. 7). Cubic faces very rare; octahedral also, but sometimes in complete octahedrons (Elba). In irregular embedded grains. Also massive; granular, coarse, or fine, and sometimes friable; lamellar, lamellæ thick and bent. Also very compact, cryptocrystalline like nephrite.

7.



Heddle.

Cleavage (or parting): *d* sometimes rather distinct[13]. Fracture subconchoidal to uneven. Brittle, sometimes friable when granular massive; very tough when compact cryptocrystalline. H. = 6·5–7·5. G. = 3·15–4·3, varying with the composition. Luster vitreous to resinous. Color red, brown, yellow, white, apple-green, black; some red and green, colors often bright. Streak white. Transparent to subtranslucent. Asterism observed in some garnets having striated faces (Dx.). Often exhibits anomalous double refraction. Refractive indices[15].

| | | | |
|---|---|---|---|
| *Grossularite*, yw.-brown, Auerbach | $n_r$ = 1·7368 Li | $n_y$ = 1·7468 Na | $n_{gr}$ = 1·7593 Tl |
| " red, " | " = 1·7645 " | " = 1·7714 " | " = 1·7796 " |
| *Pyrope*, Oriental | " = 1·7776 | " = 1·8141 " | $n_v$ = 1·8288 |
| *Almandite*, Ceylon | " = 1·7716 red | Also, Zillerthal | $n_y$ = 1·7670 |

Red-brown dodecahedrons from Taberg, with strong double refraction, gave, for rays ⊥ *d* and ∥ longer diagonal respectively, $n_y$ = 1·8389 and 1·8328, $n_{gr}$ = 1·8436 and 1·8387, G. Nordenskiöld.[15]

The anomalous double refraction of many garnets,[14] early noted by Brewster, was fully studied by Mallard and later by Bertrand, by whom it has been explained as due to the complex twinning of triclinic individuals, producing at times forms which are apparently orthorhombic and isometric. The exhaustive studies of Klein have not only developed the various types of structure, but have served to prove that the structure is immediately connected with the external form, not dependent upon the chemical composition, and doubtless of secondary origin.

In general the molecular structure may be explained by regarding the crystal as made up of a series of similar pyramids whose vertices meet at the center; many garnets show an easy mechanical separation into parts corresponding to these pyramids. Several types of forms are distinguished by Klein: (1) the *octahedral*, where the structure corresponds to eight triangular pyramids, each uniaxial and negative with the optical axis normal to the octahedral face which forms its base; this is illustrated by the octahedrons from Elba. (2) *Dodecahedral*, corresponding to the grouping of twelve rhombic pyramids, whose bases coincide with the dodecahedral faces; the axial plane is parallel to the longer diagonal, to which the bisectrix (usually −) is normal; this is the more common type. (3) *Icositetrahedral*, corresponding to twenty-four pyramids whose bases are formed by the faces of the tetragonal trisoctahedron *n* (211) to which the optic axis, or bisectrix (+ or −) of the uniaxial (or biaxial) pyramid is normal; ax. pl. ⊥ symmetric diagonal of each face of the form 211. (4) *Hexoctahedral*, corresponding to forty-eight triangular pyramids, the bases having the position of the faces of the vicinal hexoctahedron of topazolite. Each pyramid is biaxial; bisectrix (−) inclined to the hexoctahedral face; ax. pl. variable.

Besides the distinct types mentioned, many garnets show optical characters more or less intermediate between them. Klein's observations prove that the normal form of the garnet is isometric, while the anomalous optical structure is secondary. Brögger calls attention to the fact that garnets in igneous rocks which have been formed direct from the magma, or embedded crystals in rocks formed by regional metamorphism, are uniformly isotropic, while those which have apparently crystallized from hot solutions in crevices or have been formed by contact metamorphism, for example in crystallized limestone, exhibit double refraction.

**Comp., Var.**—An orthosilicate having the general formula $\overset{\text{II}}{R}_3\overset{\text{III}}{R}_2(SiO_4)_3$ or $3RO.R_2O_3.3SiO_2$. The bivalent element is calcium, magnesium, ferrous iron or manganese; the trivalent element, aluminium, ferric iron and chromium, and rarely titanium; further, silicon is also sometimes replaced by titanium.

There are three prominent groups, and various subdivisions under each, many of these blending into each other.

I. *Aluminium Garnet*, including

| | | |
|---|---|---|
| A. GROSSULARITE | Calcium-Aluminium Garnet | $Ca_3Al_2Si_3O_{12}$ |
| B. PYROPE | Magnesium-Aluminium Garnet | $Mg_3Al_2Si_3O_{12}$ |
| C. ALMANDITE | Iron-Aluminium Garnet | $Fe_3Al_2Si_3O_{12}$ |
| D. SPESSARTITE | Manganese-Aluminium Garnet | $Mn_3Al_2Si_3O_{12}$ |

II. *Iron Garnet*, including

| | | |
|---|---|---|
| E. ANDRADITE | Calcium-Iron Garnet | $Ca_3Fe_2Si_3O_{12}$ |

(1) Ordinary. (2) Magnesian. (3) Titaniferous. (4) Yttriferous

III. *Chromium Garnet.*

| | | |
|---|---|---|
| F. UVAROVITE | Calcium-Chromium Garnet | $Ca_3Cr_2Si_3O_{12}$ |

The name Garnet is from the Latin *granatus*, meaning *like a grain*, and directly from *pomegranate*, the seeds of which are small, numerous, and red, in allusion to the aspect of the crystals.

A. GROSSULARITE. Essonite or Hessonite. Cinnamon Stone. Kaneelstein. *Calcium-aluminium Garnet.* Kalkthongranat *Germ.* Formula $3CaO.Al_2O_3.3SiO_2$ = Silica 40·0, alumina 22·7, lime 37·3 = 100. Often containing ferrous iron replacing the calcium, and ferric iron replacing aluminium, and hence graduating to groups C and E. G = 3·55 to 3·66. Color (*a*) white; (*b*) pale green; (*c*) amber-and honey-yellow; (*d*) wine-yellow, brownish yellow, cinnamon-brown; (*e*) pale rose-red; rarely (*f*) emerald-green from the presence of chromium.

The original *grossularite* (*wiluite* pt.) included the pale green from Siberia, and was so named from the botanical name for the gooseberry; G. =3·42–3·72. *Cinnamon-stone*, or *essonite* (more properly *hessonite*), included a cinnamon-colored variety from Ceylon, there called *hyacinth*; but under this name the yellow kinds are usually included; named from *ἥσσων*, *inferior*, because of less hardness than the true hyacinth which it resembles. *Succinite* is an amber-colored kind from the Ala valley, Piedmont. *Romanzovite* is brown. A garnet from R. Iset, Govt. Perm, is compact, grayish green to greenish white in color, and much resembles nephrite; anal. 22, 23.

Pale green, yellowish, and yellow-brown garnets are not invariably grossularite; some (including topazolite, demantoid, etc.) belong to the group of Calcium-Iron Garnet, or Andradite.

Anals. 21, 22 are of two specimens closely resembling nephrite, massive, compact, of a grayish green or grayish white color.

B. PYROPE. Precious garnet pt. *Magnesium-aluminium Garnet.* Magnesiathongranat *Germ.* Formula $3MgO.Al_2O_3.3SiO_2$ = Silica 44·8, alumina 25·4, magnesia 29·8 = 100. Magnesia predominates, but calcium and iron are also present, and the original pyrope contained chromium. G. = 3·70–3·75. Color deep red to nearly black. Often perfectly transparent and then prized as a gem. The name *pyrope* is from *πυρωπός, fire-like.*

C. ALMANDITE. Almandine. Precious garnet pt. Common garnet pt. *Iron-aluminium Garnet.* Eisenthongranat *Germ.* Formula $3FeO.Al_2O_3.3SiO_2$ = Silica 36·2, alumina 20·5, iron protoxide 43·3 = 100. Ferric iron replaces the aluminium to a greater or less extent (cf. anals. 13–19). Magnesium also replaces the ferrous iron, and thus it graduates toward pyrope. G. = 3·9–4·2. Color fine deep red, transparent, in *precious garnet;* brownish red, translucent or subtranslucent, in *common garnet;* black. Part of *common garnet* belongs to *Andradite.*

The Alabandic carbuncles of Pliny were so called because cut and polished at Alabanda. Hence the name almandine, now in use. Pliny describes vessels of the capacity of a pint, formed from carbuncles, "non claros ac plerumque sordidos ac semper fulgoris horridi," devoid of luster and beauty of color, which probably were large common garnets of the latter kind.

E. ANDRADITE. Common Garnet, Black Garnet, etc. *Calcium-iron Garnet.* Kalkeisengranat *Germ.* Formula $3CaO.Fe_2O_3.3SiO_2$ = Silica 35·5, iron sesquioxide 31·5, lime 33·0 = 100. Aluminium replaces the ferric iron; ferrous iron, manganese and sometimes magnesium replace the calcium. G. = 3·8–3·9. Colors various: wine-, topaz-, and greenish yellow, apple-green to emerald-green; brownish red, brownish yellow; grayish green, dark green; brown; grayish black, black.

Named *Andradite* after the Portuguese mineralogist, d'Andrada, who in 1800 described and named one of the included subvarieties, Allochroite. The included kinds vary so widely in color and other respects that no one of the names in use will serve for the group.

Chemically there are the following subvarieties: 1. Simple *Calcium-iron Garnet,* in which the protoxides are wholly or almost wholly lime. Includes: (*a*) *Topazolite,* having the color and transparency of topaz, and also sometimes green; although resembling hessonite, Damour has shown that it belongs here. *Demantoid* is a grass-green to emerald-green variety with brilliant luster and occurring in massive forms; it is used as a gem, and its name refers to its high luster, resembling that of the diamond. (*b*) *Colophonite,* a coarse granular kind, brownish yellow to dark reddish brown in color, resinous in luster, and usually with iridescent hues; named after the resin *colophony.* Part of what has been called colophonite is vesuvianite. (*c*) *Melanite* (from *μέλας, black*), black, either dull or lustrous; but all black garnet is not here included. *Pyreneite* is grayish black melanite; the original afforded Vauquelin 4 p. c. of water, and was iridescent, indicating incipient alteration. (*d*) Dark green garnet, not distinguishable from some allochroite, except by chemical trials. *Jelletite* is green garnet, light or dark, and yellowish green, from the moraine of the Findelen glacier near Zermatt; named after Jellet, one of its describers. *Calderite* is a massive garnet from India; one kind, resembling colophonite, occurs in beds in the Hazáribágh district, anal. 22.

2. *Manganesian Calcium-iron Garnet.* (*a*) *Rothoffite.* The original ~~*allochroite*~~ was a manganesian iron-garnet of brown or reddish brown color, and of fine-grained massive structure. The *Rothoffite*, from Långban, first analyzed by Rothoff, is similar, with the color yellowish brown to liver-brown. Other common kinds of manganesian iron-garnet are light and dark, dusky green and black, and often in crystals. Thomson's *Polyadelphite* was a massive brownish yellow kind, from Franklin, N. J. (anal. 19, 20). The same locality affords another in dark green crystals, containing still more manganese. Bredbergite is a variety from Sala analyzed by Bredberg (anal. 21) which contains a large amount of magnesium.

(*b*) *Aplome* (properly haplome) has its dodecahedral faces striated parallel to the shorter diagonal, whence Haüy inferred that the fundamental form was the cube; and as this form is simpler than the dodecahedron, he gave it a name derived from ἁπλόος, simple. Color of the original aplome (of unknown locality) dark brown; also found yellowish green and brownish green at Schwarzenberg in Saxony, and on the Lena in Siberia.

3. *Titaniferous.* Contains titanium and probably both TiO$_2$ and Ti$_2$O$_3$; formula hence 3CaO.(Fe,Ti,Al)$_2$O$_3$.3(Si,Ti)O$_2$. It thus graduates toward schorlomite. Color black. Cf. Knop, Rg., Koenig (refs. under analyses beyond).

4. *Yttriferous Calcium-iron Garnet; Yttergarnet.* Contains yttria. A Norwegian garnet analyzed by Bergemann yielded 6·66 p. c. of the yttrium earths; later analyses (anal. 26) from the same locality (Stokö) afforded very little, thus throwing doubt over Bergemann's results. Websky found 2·6 p. c. of yttrium earths in an almandite from Schreiberhau, anal. 20, p. 442.

[a] Includes some $Fe_2O_3$.

**Pyr., etc.**—Most varieties fuse easily to a light brown or black glass; F. = 3 in almandite, spessartite, grossularite, and allochroite; 3·5 in pyrope; but uvarovite, the chrome-garnet, is almost infusible, F. = 6. Allochroite and almandite fuse to a magnetic globule. Reactions with the fluxes vary with the bases. Almost all kinds react for iron; strong manganese reaction in spessartite, and less marked in other varieties; a chromium reaction in uvarovite, and in most pyrope. Some varieties are partially decomposed by acids; all except uvarovite are after ignition decomposed by hydrochloric acid, and generally with separation of gelatinous silica on evaporation. Decomposed on fusion with alkaline carbonates.

As shown by Magnus, the density of garnets is largely diminished by fusion. Thus a Greenland garnet fell from 3·90 to 3·05 on fusion, and a Vilui grossularite from 3·63 to 2·95. Further a brownish red Arendal garnet, having G. = 4·058, was reduced by heating to G. = 4·046, and by fusion to 3·596–3·204, Church; and a Ceylon hessonite, having G. = 3·666, had G. = 3·682 after heating to incipient fusion, Church. Cf. Magnus, Pogg., **22**, 391, 1831; Kbl., Schw. J., **64**, 283, 1832; Church, J. Ch. Soc., **17**, 386, 1864.

**Obs.**—Garnet in crystals or rounded grains is very common in mica schist, gneiss, syenitic gneiss and hornblende and chlorite schist; occurs often, also, in granite, syenite, crystalline limestone, sometimes in serpentine, and occasionally in volcanic rocks, lava and tufas; further, occasionally observed in lithophyses of rhyolite and as a product of contact metamorphism.

Garnet is sometimes found in the massive form as a prominent constituent of a rock. A white variety (lime-alumina garnet) occurs, forming, with a little serpentine, a whitish garnet rock at Orford in Canada, having G. = 3·52–3·53. A similar *garnet-felsyte* exists in Bayreuth in Bavaria. At St. François in Canada there is a yellowish white and greenish white garnet rock, consisting of the same garnet along with pyroxene, in the proportion, according to T. S. Hunt, of 57·7 of the former to 40·7 of the latter, having G. = 3·33 (Rep. G. Can., 496, 1863). *Eclogyte* is a *garnet-euphotide*, consisting of a massive reddish garnet and grass-green smaragdite or omphacite. These garnet rocks are all very tough as well as heavy rocks.

Garnet crystals often contain inclusions of foreign matter, but only in part due to alteration; as, vesuvianite, calcite, epidote, quartz (f. 8); at times the garnet is a mere shell, or perimorph, surrounding a nucleus of another species. A black garnet from Arendal, Norway, contains both calcite and epidote; crystals from Tvedestrand are wholly calcite within, there being but a thin crust of garnet. Crystals from East Woodstock, Maine, are dodecahedrons with a thin shell of cinnamon-stone enclosing calcite; others from Raymond, Me., show successive layers of garnet and calcite. Many such cases have been noted.

Crystals of garnet in the form of thin flat disks are not infrequently observed embedded between plates of mica.

The garnet of granite, gneiss, granulyte, mica schists, and similar rocks is chiefly the iron-aluminium variety, *almandite*, but includes also andradite and the isomorphous varieties intermediate between them. *Grossularite* is especially common in crystalline limestone, where it is associated with vesuvianite, wollastonite, diopside, etc.; it occurs also in crystalline schists. *Pyrope* belongs peculiarly to peridotytes and the serpentines formed from them; occurs also in basalt. *Spessartite* occurs in granitic rocks, in quartzyte, in whetstone schists (Belgium); it has been noted with topaz in lithophyses in rhyolyte (Colorado). The black variety of andradite, *melanite*, is common in eruptive rocks, especially with nephelite, leucite, thus in phonolytes, leucitophyres, nephelinytes; it also occurs as a product of contact metamorphism. *Demantoid* occurs in serpentine. *Uvarovite* belongs particularly with chromite in serpentine; it occurs also in granular limestone.

8.

Garnet enclosing quartz, Heddle.

Many foreign localities of garnet have been mentioned in the preceding pages, under the head of *composition* and *varieties*. The best *cinnamon-stone* comes from Ceylon, in gneiss; also from Malsjö in Wermland, in crystalline limestone; on the Mussa-Alp in the Ala valley in Piedmont, with clinochlore and diopside; at Mittagshorn, Saasthal, Switzerland, with the same minerals, reddish brown in color, also from Zermatt; pale isabella-yellow at Auerbach; nearly colorless dodecahedral crystals at Gleinitz near Jordansmühl, Silesia; a brownish variety (*romanzovite*) at Kimito in Finland. A honey-yellow garnet in *octahedrons* occurs in Elba. Grossularite of pale greenish color comes from the banks of the Vilui in Siberia; in serpentine with vesuvianite, also from Cziklowa and Orawitza in the Banat; honey-yellow to green or brown crystals at Rezbánya; with vesuvianite and wollastonite in ejected masses at Vesuvius; in white or colorless crystals in Tellemark, in Norway, and the Shishimsk Mts., in the Ural; also whitish in a resinopal pseudomorph after coral in Tasmania; in groups of dark brown dodecahedrons at Mudgee, New South Wales; dark honey-yellow dodecahedrons with pyrite at Guadalcazar, and clear pink dodecahedrons (G.=3·46 Pirsson) at Morelos, Mexico (see p. 1035).

*Pyrope* occurs in serpentine (from peridotyte), a serpentine conglomerate, and in the sands of the region, near Meronitz, Třziblitz, and Podsedlitz, in Bohemia, where the variety used as a gem is obtained; also at Zöblitz and Greifendorf in Saxony; the valley of Krems (Křemže) near Budweis in Bohemia, in a serpentine rock; in the Vosges; Elie in Fife, Scotland, the "Elie rubies;" in the diamond diggings of South Africa, as at Kimberley, see p. 5 ("Cape rubies"); reported from Burma. *Almandite* is common in granite, gneiss, eclogyte, etc., in many localities in Saxony, Silesia, etc.; at Eppenreuth near Hof, Bavaria (in eclogyte); in dodecahedrons 3 to 4 inches through at Falun in Sweden, in hyacinth-red or brown crystals in the Zillerthal and Oetzthal, Tyrol. Precious garnet comes in fine crystals from Ceylon, Pegu, Brazil, and Greenland; also from the Sarwar mines in Rajputana and at Kakoria in Jaipur in British India. *Spessartite* is from Aschaffenburg in the Spessart, Bavaria; in the white feldspar of the granite of Elba; at St. Marcel, Piedmont; in pegmatyte at Vilate near Chanteloube, Haute-Vienne; at Broddbo, near Falun, in Sweden; Ilefeld in the Harz; in the whetstone slates of the Ardennes at Viel Salm, Ottrez, Salm-Chateau, Belgium; in Ross-shire and other points in Scotland. (Cf. Heddle, l.c.)

Among the varieties of the calcium-iron garnet, *andradite*, the beautiful green *demantoid* or "Uralian emerald" occurs in transparent greenish rolled pebbles, also in crystals, in the gold washings of Nizhni-Tagilsk in the Ural: also in the stream Bobrovka, 10 versts S.W. from Poldnevaya in the Sisersk on the west slope of the Ural; first found in loose pieces, later in a serpentine rock, embedded in fibrous serpentine; green crystals occur at Schwarzenberg, Saxony; brown to green crystals at Morawitza and Dognacska; emerald-green at Dobschau; in the Ala valley, Piedmont, the yellow to greenish *topazolite*, with its characteristic vicinal hexoctahedron (ζ). *Allochroite*, an apple-green and yellowish variety, of different shades, occurs at Zermatt, in geodes of crystals in chlorite schist; brilliant black crystals (*melanite*) and also brown, at Vesuvius on Mte. Somma; and in a volcanic tufa at Frascati near Rome; in Baden at the Kaiserstuhl; Pic d'Espada and that of Ereslids near Barèges in the Hautes-Pyrénées (*Pyreneite*). *Aplome* occurs in yellowish and brownish green crystals at Schwarzenberg in Saxony, and on the borders of the Lena in Siberia; brown to black crystals, highly modified, in the Pfitschthal, Tyrol; other localities are Långban in Sweden, Pitkäranta in Finland, Arendal in Norway, whence very large dodecahedral crystals are obtained. *Uvarovite* is found at Saranovskaya near Bisersk, also in the vicinity of Kyshtymsk, Ural, lining cavities or fissures in chromic iron; at Hanle, in Rupshu in the western Himalayas; at Jordansmühl, Silesia; Pic Posets near Vénasque in the Pyrenees on chromite. It is named after the Russian Count Uvarov.

Near Cauterets, in the Hautes-Pyrénées, large crystals of brown garnet have a nucleus, easily separable, of dull green crystallized vesuvianite; the containing rock is a compact gray limestone.

In N. America, in *Maine*, beautiful yellow crystals or cinnamon-stone (with vesuvianite) at Parsonsfield, Phippsburg, and Rumford; manganesian garnet at Phippsburg, as well as fine yellow garnet; in mica slate near the bridge at Windham, with staurolite; in granite veins at Streaked Mountain, along with beryl; in large reddish brown crystals at Buckfield, on the estates of Mr. Waterman and Mr. Lowe; handsome red garnets at Brunswick. In *N. Hamp.*, at Hanover, small clear crystals in syenitic gneiss; blood-red dodecahedrons at Franconia, in geodes in massive garnet, with calcite and magnetic iron; at Haverhill, in chlorite, some 1½ in.; at Warren, beautiful cinnamon garnets with green pyroxene; at Unity, on the estate of J. Neal, with actinolite and magnetite, and at Lisbon, near Mink Pond, in mica slate with staurolite; at Grafton, ¼ to 1 in. in diameter. In *Vermont*, at New Fane, large crystals in chlorite slate; also at Cabot and Cavendish. In *Mass.*, at Carlisle, geodes of transparent cinnamon-brown crystals similar to figure 4, with scapolite in limestone; also in gneiss at Brookfield and Brimfield; in crystals at Bedford, Chesterfield, with the Cummington cyanite, and at the beryl locality of Barre; fine dark red or nearly black trapezohedral crystals at Russell, sometimes very large; red garnets at Chester. In *Conn.*, trapezohedrons, ¼ to 1 in., in mica slate, at Reading and Monroe; dodecahedrons at Southbury; at Haddam, crystals of manganesian garnet, often 2 in. through, with chrysoberyl; at Lyme, large blackish brown crystals in limestone; near New Haven, at Mill Rock in trap at junction with sandstone in pale yellow brown crystals (f. 6) resembling topazolite, also melanite (anal. 10) at East Rock on faces of trap in rosettes of dodecahedrons with magnetite, etc; manganesian garnet at Branchville.

In *N. York*, in mica slate, in Dover, Dutchess Co., small; at Roger's Rock, crystallized and massive, and colophonite of yellow, brown, and red colors, abundant; brown crystals at Crown Point, Essex Co.; colophonite as a large vein in gneiss at Willsboro, Essex Co., with wollastonite and green coccolite, and also at Lewis, 10 m. south of Keeseville; in Middletown, Delaware Co., large brown cryst.; a cinnamon variety, crystallized and massive, at Amity; on the Croton aqueduct, near Yonkers, in small rounded crystals, and a beautiful massive variety—the latter, when polished, forms a beautiful gem; oil-green dodecahedrons at the magnetite iron mine, Brewster, Putnam Co.; a large garnet weighing nearly 10 lbs. and with a maximum diameter of 6 inches was found in an excavation in New York City, in West 35th Street, in 1885. In *N. Jersey*, at Franklin, black, brown, yellow, red, and green dodecahedral garnets; also near the Franklin furnace polyadelphite. In *Penn.*, in Chester Co., at Pennsbury, fine dark brown crystals with polished faces, in granite; near Knauertown, at Keims' mine, in handsome lustrous crystals; at Chester, brown; in Concord, on Green's Creek, resembling pyrope; in Leiperville, red; at Mineral Hill, fine brown; at Warren, black; at Avondale quarry, fine hessonite; uvarovite at Woods' chrome mine, Lancaster Co. In *Delaware*, cinnamon-stone in trapezohedrons, at Dickson's quarry, 7 m. from Wilmington. In *Virginia*, beautiful transparent spessartite, used as a gem, at the mica mines at Amelia Court House. In *N. Carolina*, fine cinnamon-stone at Bakersville; red garnets in the gold washings of Burke, McDowell, and Alexander counties; also mined near Morgantown and Warlich, Burke Co., to be used as "emery," and as "garnet-paper;" a garnet-rock at Burnsville, Yancey Co. In *Kentucky*, fine pyrope in the peridotyte of Ellis Co. In *Arkansas*, at Magnet Cove, a titaniferous melanite with schorlomite. Large dodecahedral crystals entirely altered to chlorite occur at the Spurr Mt. iron mine, Lake Superior (Pumpelly).

In *Colorado*, at Nathrop, fine spessartite crystals in lithophyses in rhyolyte with quartz and topaz. In large dodecahedral crystals up to 14½ lbs. in weight at Ruby Mt., Salida, Chaffee Co., the exterior is usually green from a layer of a chlorite (see p. 660) due to alteration. In *Nevada*, small but fine red garnets in Ruby Valley, Elko Co.; at Black Cañon, Colorado R.; almandite in White Pine Co. In *Arizona*, yellow-green crystals in the Gila cañon; pyrope on the Colorado River in the western part of the territory. *New Mexico*. fine pyrope on the Navajo reservation associated with chrysolite and a chrome-pyroxene. In *California*, green with copper ore, Hope Valley, El Dorado Co., on Rogers' claim; also with copper ore in Los Angeles Co., in Mt. Meadows; uvarovite, in crystals on chromite, at New Idria; uvarovite in serpentine with chromite on the American river below Towle's station on the Central Pacific R.R. Common garnets at many points. Fine crystals (f. 4) of ideal symmetry of a rich red color and an inch or more in diameter occur in the mica schists at Fort Wrangell, mouth of the Stickeen R., in *Alaska*.

In *Canada*, at Marmora, dark red; at Grenville, a cinnamon-stone; an emerald-green chrome-garnet at Orford, Quebec, in granular masses and druses of minute transparent dodecahedral crystals, with millerite and calcite; and in the same vicinity large cinnamon-red and yellowish crystals of garnet along with pyroxene; fine colorless to pale olive-green, or brownish crystals, at Wakefield, Ottawa Co., Quebec, with white pyroxene, honey-yellow vesuvianite, etc., also others bright green carrying chromium; dark red garnet in the townships of Villeneuve (spessartite) and Templeton; pale yellow at N. Elmsby.

In jewelry, the lighter clear garnets are often called hyacinth. The yellowish is the *Jacinta la bella;* a yellowish crimson, the *Guarnaccino;* and another very similar, *Vermeille*, or *Hyacinth-Garnet;* the red, with a violet tinge, *Rubino-di-rocca*, and also *Grenat Syrian* (from Syriam in Pegu), and probably the *Amethystizontes* of Pliny. The deep and clear red, like Burgundy wine in shade, is the true *precious garnet*, which is either pyrope or almandite. The ancient name ἄνθραξ, meaning *a burning coal*, alludes to the internal fire-like color and reflection, and was applied also to some ruby. The Latin name *carbunculus*, from *carbo, coal*, has the same signification.

**Alt.**—Garnets containing ferrous iron often become rusty and disintegrated through the oxidation of the iron, and sometimes are altered, more or less completely, to *limonite, magnetite*, or *hematite*. The action of waters containing traces of carbon dioxide and carbonates and silicates in solution results in the same changes nearly as with pyroxene, producing at different times a loss, or alteration, of bases, or by a further change and the addition of water, *steatite*, *serpentine, chlorite.* The lime in the lime garnets may be taken up by the carbonic acid of the waters; and if magnesia is combined with the carbonic acid, it may take the place of the lime, and thus give rise to a *serpentine* or *steatite* pseudomorph, or to a *chlorite,* if the iron partly remains. Alkaline carbonates seldom produce the changes, for alkaline pseudomorphs are rare. An excess of silica is to be expected in analyses, according to Bischof, since part of the bases is often lost through incipient change. Quartz also occurs with the form of garnet.

The common iron-aluminium garnet is especially liable to alteration, and besides the changes noted above, pseudomorphs of scapolite, mica, oligoclase, epidote, amphibole have been noted (cf. Cathrein, below). The calcium-iron garnet yields pseudomorphs of epidote, chlorite, serpentine, orthoclase.

The magnesium-aluminium garnet, pyrope, is also frequently altered, forming chlorite, serpentine, and various more or less definite substances. Schrauf's *kelyphite* (Vh. G. Reichs., 244, 1879, Zs. Kr., **6**, 359, 1882) forms a zone about a nucleus of pyrope (hence from *κέλυφος, a nut shell*) at Krems, Bohemia. Its composition is given by the analysis below, but Lasaulx (l. c.) has shown that it is not a homogeneous substance.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | |
|---|---|---|---|---|---|---|---|---|---|
| *Kelyphite* | G.=3·064 | 40·41 | 13·35 | 2·47 | 7·02 | 0·31 | 27·40 | 5·05 | ign. 2·21, $Cr_2O_3$ 1·75=99·97 |

On the alteration of garnet, see Blum, Pseudomorphosen, Roth, Ch. Geologie, **1**; also the following: Helland, Pogg., **145**, 480, 1872; Saualpe, Niedzwiedski, Min. Mitth., 162, 1872; Lsx., Ber. nied. Ges., July 3, 1882; serpentine region near Budweis, Bohemia, Schrauf, Zs. Kr., **6**, 321, 1882, and Lsx., **8**, 303, 1883; altered garnets in amphibolyte, Tyrol, Cathrein, Zs. Kr., **10**, 433, 1885; Lake Superior, crystals altered to chlorite, Pumpelly, Am. J. Sc., **10**, 17, 1875; L. Superior and Colorado, Penfield and F. L. Sperry, Am. J. Sc., **32**, 307, 1886.

For the analyses of the various kinds of "chlorite" produced by the alteration of garnet, *e.g.* that of L. Superior, Salida, Col., see under the CHLORITE GROUP, p. 660.

**Artif.**—Obtained artificially with difficulty, except the manganesian variety, spessartite, which has been formed by Gorgeu from fusion of the constituents in magnesium chloride; also by Bourgeois with arborescent crystallites of hausmannite. The fusion of garnet ordinarily results in the separation into such compounds as pyroxene, melilite, monticellite, scapolite, anorthite. Melanite with nephelite has been formed, however, from fusion by Fouqué and Lévy. Also early reported that melanite garnets have been obtained in a glass proceeding from the fusion of vesuvianite (Klaproth) and of a melanite from Frascati (by Kobell). Miller mentions the occurrence of garnet in crystals as a furnace product. Cf. Bourgeois, Ann. Ch. Phys., **29**, 458, 1883, and Reprod. Min., 121, 1884; Doelter, Jb. Min., **1**, 158, 1884; Fouqué & Lévy, Bull. Soc. Min., **2**, 105, 1879, also Synth. Min., 121, 1882; Gorgeu, Bull. Soc. Min., **6**, 283, 1883.

TRAUTWINITE *E. Goldsmith,* Proc. Ac. Philad., pp. 9, 348, 365, 1873. An impure uvarovite (Genth) occurring with chromite from Monterey Co., Cal.

**371. SCHORLOMITE.** *Shepard,* Am. J. Sc., **2**, 251, 1846. Ferrotitanite *Whitney,* J. Nat. Hist. Boston, **6**, 45, 1849. Schorlamit *Rg.*

Iwaarit *Kutorga,* 1851. *N. Nd.*, Verz. Finl. Min., 1852. Ivaarite.

Isometric, in trapezohedrons and dodecahedrons (?). Usually massive, without cleavage.

Fracture conchoidal. H. = 7–7·5. G. = 3·81–3·88. Luster vitreous. Color black, sometimes tarnished blue, and with pavonine tints. Streak grayish black. Optically isotropic like garnet, Dx.

**Comp.**—Probably analogous to garnet, $3CaO.(Fe,Ti)_2O_3.3(Si,Ti)O_2$.

Cf. Rg., Min. Ch., Erg., 201, 1886, Koenig, Proc. Acad. Philad., 355, 1886.

| 4. | " " | 3·876 | 25·80 | 12·46 | 23·20 | 0·46[a] | 31·40 | 1·22 | $Ti_2O_3$ 4·44, $Al_2O_3$ 1·00 = 99·98 |

[a] MnO.

The mineral was first correctly described and analyzed by Whitney, l. c. Shepard made it a hydrous silicate of iron sesquioxide, yttria, and perhaps thoria. Koenig showed that it could be referred to the Garnet Group, an idea earlier suggested by Rg. and others.

**Pyr., etc.**—B.B. fuses quietly at 3 to a black glass. Reactions for iron with the fluxes. Fused with salt of phosphorus on charcoal, with tin, in the inner flame, gives a violet bead. Gelatinizes with hydrochloric acid, the solution becoming violet when boiled with metallic tin (titanium).

**Obs.**—In small masses with elæolite and brookite in the Ozark Mts., Magnet Cove, Arkansas. It occurs intimately associated with black garnet forming parts of garnet crystals and probably has itself the same form. A titaniferous garnet resembling it occurs in the Kaiserstuhl, near Oberschaffhausen, in phonolyte. Cf. Knop, l. c. and analyses, p. 444. Named from a resemblance to schorl (black tourmaline).

IVAARITE *N. Nordenskiöld*, Beskr. Finl. Min., 101, 1855. Has the characters of schorlomite, and like it is found with elæolite. It occurs both massive and in garnet-like crystals, is lustrous black and opaque, with adamantine luster. H. = 6·0, and G. = 3·67–3·69. The mineral is stated on the basis of an unpublished analysis of Thoreld to have the percentage composition (calculated): $SiO_2$ 29·15, $TiO_2$ 18·98, $Fe_2O_3$ 25·26, CaO 26·61 = 100, which corresponds very closely to schorlomite. B.B. fuses to a black glass. From Ivaara in Kuusamo, Finland.

---

## MONOCLINIC SPECIES RELATED TO THE FOREGOING.

Partschinite and Agricolite have respectively the composition of spessartite and eulytite. Both species need further examination.

**372. PARTSCHINITE.** Partschin *Haid.*, Ber., **3**, 440, 1847, Ber. Ak. Wien, **12**, 480, 1854.

Monoclinic. In small dull crystals somewhat resembling augite.

**Forms:** *a* (100, *i-ī*), *c* (001, *O*), *m* (110, *I*), *e* (011, 1-ì), *p* ($\bar{1}12$, ½). Angles (meas. Foetterle) *mm'''* = 88° 8', *ac* = 52° 16', *ee'* = 64°, also (calc.) *cp* = 53° 8', *pp'* = 76° 34'.

Fracture subconchoidal. H. = 6·5–7. G. = 4·006 Hauer. Luster a little greasy, feeble. Color yellowish, reddish. Subtranslucent.

**Comp.**—$(Mn,Fe)_3Al_2Si_3O_{12}$ like spessartite.

**Anal.**—1, 2, Hauer. Another incomplete analysis gave 46·72 p. c. $SiO_2$.

| $SiO_2$ | $Al_2O_3$ | FeO | MnO | CaO | $H_2O$ |
|---|---|---|---|---|---|
| 35·28 | 19·03 | 14·38 | 29·11 | [1·82] | 0·38 = 100 |
| 34·89 | 18·95 | 13·86 | 29·34 | 2·77 | |

**Obs.**—In very small dull crystals and rounded fragments, in the auriferous sands of Oláhpian, Transylvania; attention was early called to them by Breithaupt.

**373. AGRICOLITE.** *Frenzel*, Jb. Min., 791, 947, 1873; 686, 1874.

Monoclinic, Groth. $\beta = 70°$. In globular or semi-globular forms, with radiated or fibrous structure. Also in indistinct groups of crystals. Soft, brittle, heavy. Luster adamantine, greasy. Colorless to wine-yellow, hair-brown.

**Comp.**—As for eulytite, $Bi_4Si_3O_{12}$.

**Anal.**—Frenzel, l. c.

$SiO_2$ 16·67 $Bi_2O_3$ 81·82 $Fe_2O_3$ 0·90 = 99·39

**Obs.**—Occurs at Johanngeorgenstadt on quartz, associated with native bismuth, cloanthite, bismite; also at the mine Neuglück, Schneeberg.

Includes, according to Frenzel, the *arsenwismuth* of Breithaupt. Arsenik-Wismuth *Wern.* Breith. Letzt. Min. Syst., 23, 62, Hoffm., **4**, 65, 1817. Formerly included with eulytite.

Named for the Saxon mineralogist, Georg Agricola (1490–1555).

## 5. Chrysolite Group. $R_2SiO_4$. Orthorhombic.

| | | | |
|---|---|---|---|
| 374. | Monticellite | $CaMgSiO_4$ | $\breve{a} : \bar{b} : \dot{c} = 0·4337 : 1 : 0·5758$ |
| 375. | Forsterite | $Mg_2SiO_4$ | $0·4656 : 1 : 0·5865$ |
| | Boltonite | | |
| 376. | Chrysolite | $(Mg,Fe)_2SiO_4$ | |
| | Hyalosiderite | | |
| 376A. | Hortonolite | $(Fe,Mg,Mn)_2SiO_4$ | |
| 376B. | Titan-Olivine | | |
| 377. | Fayalite | $Fe_2SiO_4$ | $0·4584 : 1 : 0·5793$ |
| 378. | Knebelite | $(Fe,Mn)_2SiO_4$ | |
| 379. | Tephroite | $Mn_2SiO_4$ | $0·4600 : 1 : 0·5939$ |
| 379A. | Roepperite | $(Fe,Mn,Zn)_2SiO_4$ | |

In form the species of the Chrysolite Group, $R_2SiO_4$, are closely related in angle to Chrysoberyl, $BeAl_2O_4$; also somewhat less closely to the species of the Diaspore Group, $H_2Al_2O_4$, etc. Cf. Brögger, Zs. Kr., **18**, 377, 1890.

---

**374. MONTICELLITE.** *Brooke*, Phil. Mag., **10**, 265, 1831. Batrachit *Breith.*, Char., **307**, 1832. Sacchit [misprint for Scacchit?] *N. Nordenskiöld,* Atom. Ch. Min. Syst., 94, 1848.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·43375 : 1 : 0·57576$ Rath[1].
$100 \wedge 110 = 23° 27'$, $001 \wedge 101 = 53° 0\frac{1}{2}'$, $001 \wedge 011 = 29° 55\frac{5}{6}'$.

**Forms**[1]: *m* (110, *I*) *d* (101, 1-ĭ) *k* (021, 2-ĭ) *f* (121, 2-2̆)

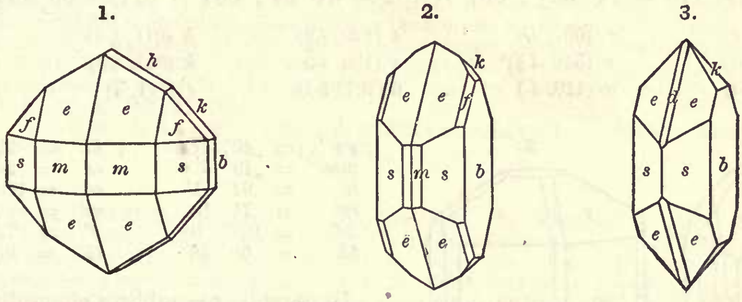
| *dd'* = 106° 1' | *ee'* = 98° 0' | *ff''* = 120° 43' | *ff'''* = 69° 26' |



1, Vesuvius, Rath. 2, Monzoni, Id. 3, Magnet Cove, Pirsson.

Crystals like chrysolite in habit (f. 1–3). Also in embedded crystalline grains and cleavable massive.

Cleavage: *b* distinct. Fracture subconchoidal to uneven. Brittle. H=5–5·5. G. = 3·03–3·25. Luster vitreous, slightly resinous in the massive variety. Colorless, yellowish gray, pale greenish gray, and whitish. Streak uncolored. Transparent to translucent.

**Var.**—(1) *Monticellite,* in colorless to yellowish gray crystals; the original from Vesuvius; G. = 3·119–3·245.

(2) *Batrachite,* cleavable massive, of a pale greenish gray color, or whitish; G. = 3·033, Breith.

**Comp., Var.**—$CaMgSiO_4$ or $CaO.MgO.SiO_2$ = Silica 38·5, magnesia 25·6, lime 35·9 = 100. Iron replaces part of the magnesium.

**Anal.**—1, Rg., Pogg., **109**, 569, 1860. 2, Id., ib., **51**, 446, 1840. 3, Ratn, ib., **155**, 32, 1875. 4, Genth, after deducting 4·7 p. c. apatite, Am. J. Sc., **41**, ——, 1891.

|---|---|---|---|---|---|---|---|---|---|
| 1. *Monticellite* | G. = 3·119 | | 37·89 | 5·61 | — | 22·04 | 34·92 | — | = 100·46 |
| 2. *Batrachite* | | | 37·69 | 2·99 | — | 21·79 | 35·45 | 1·27 | = 99·19 |
| 3. " | G. = 3·054 | $\frac{2}{2}$ | 38·25 | 4·30 | — | 23·05 | 34·75 | — | = 100·35 (ign. 1·31) |
| 4. Magnet Cove | G. = 3·108 | $\frac{2}{2}$ | 35·14 | 5·25 | 1·17 | 21·65 | 34·20 | 2·40 | $Al_2O_3$ 0·19 = 100 |

A chrysolite from the paleopicryte of Dillenburg, Nassau, gave Öbbeke: $SiO_2$ 42·53, MnO 6·48, MgO 35·68, CaO 14·09 = 98·78, Jb. Min., 845, 1877.

**Pyr., etc.**—B.B. rounded only on the edges. Soluble in dilute hydrochloric acid to a clear solution, which on evaporation gelatinizes.

**Obs.**—Occurs in crystals embedded in granular limestone with mica and augite, on Mte. Somma; very rare, most so-called monticellite being simply chrysolite. In small masses (*batrachite*) containing calcite and black spinel at the Toal dei Rizzoni, on the south side of Mte. Monzoni in the Tyrol. Also on the Pesmeda Alp in the same region.

Monticellite also occurs in crystals (f. 3 and anal. 4), and in grains embedded in calcite, at Magnet Cove, Arkansas; the crystals have a pale yellowish gray color and are of considerable size, up to 1 inch in length.

*Monticellite* was named after the Italian mineralogist, T. Monticelli (1759–1846); *Batrachite* from *βάτραχος*, *frog*, in allusion to the color.

**Alt.**—The crystals from Tyrol are often altered to serpentine (anal. 1), also in part consisting of an aggregate of minute fassaite crystals (anal. 2). There is a remarkable similarity in form, as noted by Rath, between the form of the original fassaite of the locality and the altered monticellite. Cf. Rath, l. c.

| | | $SiO_2$ | $Al_2O_3$ | FeO | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. *Serpentine* | G. = 2·617 | 41·31 | 1·34 | 5·73 | 6·47 | 33·08 | 12·35 | = 100·28 |

**Pyr., etc.**—B.B. unaltered and infusible. Boltonite gives traces of moisture in the closed tube and becomes colorless. Decomposed by hydrochloric acid with separation of gelatinous silica.

**Obs.**—*Forsterite* occurs in implanted crystals, with spinel and augite in ejected masses on Mte. Somma, Vesuvius; also in the Albani Mts. at the crater of Baccano, with wollastonite, garnet, spinel, etc.; with serpentine at Snarum, at Norway; in a bluish calcite at the Nikolaye-Maximilian mine, Zlatoust, Ural; in the limestone of the Schelinge Matte, Kaiserstuhl, in grains of a dull yellow color.

*Boltonite* is disseminated through a whitish crystalline limestone, at Bolton, Mass.; also at Roxbury and Littleton, Mass.; its embedded masses or crystals are often over an inch through, and rectangular in section. Part of the boltonite is altered, and then softer and hydrous, with the composition of villarsite, see under chrysolite, beyond.

*Forsterite* was named by Lévy after Mr. J. Forster, founder of the Heuland cabinet.

**Artif.**—Artificial magnesium chrysolite has been made by Ebelmen, by fusing together in a porcelain furnace a mixture of silica and magnesia, with potassium carbonate, or boric acid. Ann. Ch. Phys., **33**, 56, 1851. Also later by Hautefeuille by fusing a mixture of silica, magnesia, and magnesium chloride, ibid., **4**, 129, 1869; again by Lechartier similarly, but using calcium chloride, C. R., **67**, 44, 1868.

**Ref.**—[1] Jb. Min., **1**, 23, 1887. [2] Mlr., 318, 1852; also Lévy, l. c. [3] Hbg., Min. Not., **1**, 21, 1856. [4] Dx., N. R., 81, 1867, Min., **2**, ix, 1874.

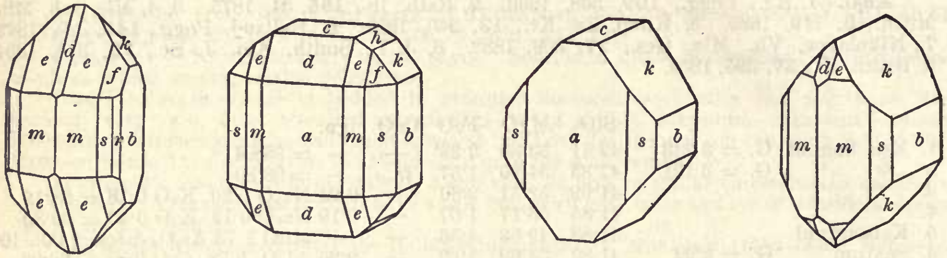
1. 2. 3. 4.

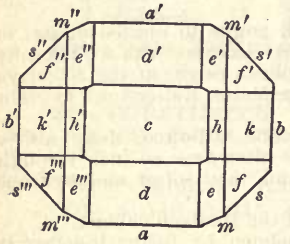


Figs. 1, Vesuvius, Rath. 2, *Oriental chrysolite,* Rose. 4, *Hyalosiderite,* Bauer.

Twins rare: (1) tw. pl. *h* (011)[5] with $c\underline{c}$ = 60° 47′, penetration-twins, sometimes repeated forming stellate trillings, similar to those of chrysoberyl; (2) tw. pl. *w* (012)[6] the vertical axes crossing at an angle of about 30° since $c\underline{c}$ = 32° 41′. Crystals often flattened ∥ *a* or *b*, less commonly elongated ∥ $\dot{c}$. Massive and compact, or granular; usually in embedded grains.

Cleavage; *b* rather distinct; *a* less so. Fracture conchoidal. Brittle. H. = 6·5–7. G. = 3·27–3·37, increasing with the amount of iron; up to 3·57 for hyalosiderite. Luster vitreous. Color green—commonly olive-green, sometimes brownish, grayish red, grayish green, becoming yellowish brown or red by oxidation of the iron. Streak usually uncolored, rarely yellowish. Transparent to translucent.

5.



Optically +. Double refraction strong. Ax. pl. ∥ *c*. Bx ⊥ *a*. Dispersion $\rho < v$, weak. Axial angles, Dx.[7]

$\alpha = 1{\cdot}661$ $\beta = 1{\cdot}678$ $\gamma = 1{\cdot}697$ for yellow (Na) ∴ $2V_y = 87° 46'$

$2H_{a.r} = 105° 58'$, $2H_{a.y} = 106° 21'$, $2H_{a.bl} = 107° 14'$, ∴ $2V_y = 88° 54'$, $2V_{bl} = 90°$ approx.
$2H_{o.r} = 108° 30'$, $2H_{o.y} = 108° 20'$, $2H_{o.bl} = 107° 57'$

**Var.**—1. *Precious.* Of a pale yellowish green color, and transparent. G. = 3·441, 3·351. Occasionally seen in masses as large as "a turkey's egg," but usually much smaller. It has long been brought from the Levant for jewelry, but the exact locality is not known.

2. *Common; Olivine* of Werner. Dark yellowish green to olive- or bottle-green. G. = 3·26–3·40; fr. Etna. Commonly disseminated in crystals or grains in basic igneous rocks, basalt and basaltic lavas, etc.

*Glinkite* is pale-green chrysolite from talcose schist; G. = 3·39–3·43 Herm.

3. *Hyalosiderite.* A highly ferruginous variety, anal. 32. It has $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}46815 : 1 : 0{\cdot}58996$, and $mm''' = 50° 10'$, $kk' = 99° 26'$, Bauer[8].

**Comp.**—$(Mg,Fe)_2SiO_4$ or $2(Mg,Fe)O.SiO_2$. The ratio of Mg : Fe varies widely, from 16 : 1, 12 : 1, etc., to 2 : 1 in hyalosiderite, and hence passing from fosterite on the one side to fayalite on the other. No sharp line can be drawn on either side. Titanium dioxide is sometimes present replacing silica; also tin and nickel in small quantities. Percentage composition, as follows:

| | $SiO_2$ | MgO | FeO | |
|---|---|---|---|---|
| Mg : Fe = 9 . 1 | 41·0 | 49·2 | 9·8 | = 100 |
| " = 5 : 1 | 39·8 | 44·3 | 15·9 | = 100 |
| " = 3 : 1 | 38·5 | 38·5 | 23·0 | = 100 |
| " = 2 : 1 | 37·2 | 33·1 | 29·7 | = 100 |

An olivine from the paleopicryte of the Schwarze Stein, Nassau, contains 14 p. c. CaO as analyzed by Oebbeke, see p. 450.

**Pyr., etc.**—B.B. whitens, but is infusible in most cases; hyalosiderite and other varieties rich in iron fuse to a black magnetic globule; some kinds turn red upon heating. With the fluxes gives reactions for iron. Some varieties give reactions for titanium and manganese. Decomposed by hydrochloric and sulphuric acids with separation of gelatinous silica.

**Obs.**—A common constituent of some eruptive rocks, especially those of a basic character where it is associated with augite, bronzite, hypersthene, also a triclinic feldspar (as labradorite), magnetite, etc. Usually in embedded grains or less commonly distinct crystals. Distinct crystals and varieties rich in iron are more common in basalt, basaltic lavas, and the immediately related rocks; also in peridotyte, dunyte, picryte; commonly in grains in olivine-diabase, olivine-gabbro, olivine-noryte. Further, not uncommon in granular limestone and dolomite, but usually varieties low in iron; sometimes an accessory constituent in hornblendic or pyroxenic crystalline schists; occasionally in ore deposits.

6.

Chrysolite chondrule from the Knyahinya meteorite (×10 diam.).

In grains, rarely crystals, embedded in some meteoric irons, especially in the siderolites or "Pallasites." In the Pallas Iron, the chrysolite is abundant and in large yellow grains, which when carefully extracted show large numbers of crystalline facets over the rounded surface (cf. Kk., l. c.); through the interior there are numerous hollow canals ∥ $\dot{c}$. The Estherville, Iowa, the Kiowa, Kansas, and the Atacama meteorites are others in which chrysolite is similarly prominent. Also present in meteoric stones, frequently in spherical forms, or chondrules, sometimes made up of a multitude of grains with like (or unlike) optical orientation inclosing glass between (f. 6).

Among the more prominent localities are: Vesuvius in lava and on Monte Somma in ejected masses, with augite, mica, etc., where fosterite also occurs, and more commonly; the crystals are sometimes associated in parallel position with clinohumite. Observed in the so-called sanidine bombs at the Laacher See, but not common; at Forstberg near Mayen in the Eifel and forming the mass of "olivine bombs" in the Dreiser Weiher near Daun in the same region; at Expailly in Haute-Loire; at Unkel, on the Rhine, crystals several inches long; at Kapfenstein in Lower Styria, in spheroidal masses; at Sasbach and Ihringen in the Kaiserstuhl, near Freiburg, Baden, in basalt, a variety containing much iron (*hyalosiderite*). In Sweden, with ore-deposits, as at Långban, Pajsberg, Persberg, etc. In serpentine at Snarum, Norway, in large crystals, themselves altered to the same mineral. In talcose schist, found near Kyshtymsk, N. of Miask, and near Sysersk in the Ural, in greenish embedded nodules (*glinkite*, anal. 26). Common in the volcanic rocks of Sicily, Hecla, the Sandwich Islands, the Azores, the Canaries, and Cape Verde Islands.

In the U. S., in Thetford and Norwich, Vermont, in boulders of coarsely cryst. basalt, the crystals or masses several inches through. In olivine-gabbro of Waterville, in the White Mts., (anal. 30), New Hampshire; at Webster, in Jackson Co., N. C., along with serpentine, pyrosclerite, and chromite; with chromite in Loudon Co., Va.; in Lancaster Co., Pa., at Wood's mine, with serpentine and chromite (Genth); near Media, Delaware Co., Pa., with bronzite and chromite. In small clear olive-green grains with garnet at some points in Arizona and New Mexico, locally called Job's tears because of their pitted surface.

In basalt in Canada, near Montreal, at Rougemont and Mounts Royal and Montarville, and in eruptive rocks at other points.

Chrysolite is named from χρυσός, *gold*, and λίθος. The hyalosiderite, from ὕαλος, *glass*, and σίδηρος, *iron*.

The *chrysolithus* of Pliny was probably our topaz; and his *topaz* our *chrysolite*. But Pliny's statement that "topazos" is the largest of all the precious stones, and that a statue 4 cubits high was made of it, shows that he confounded together different stones, since solid chrysolite crystals are never as large as some topaz crystals, and two inches is an extraordinary magnitude. The hardness mentioned, that it yields to the action of the file and wears with use, is right, and seems to prove that true chrysolite was included under the name of *topazion*. It came from an island in the Red Sea, and was very highly valued. It is stated by Diodorus Siculus to have resembled glass, but to have had a remarkable golden appearance, especially conspicuous at night (King).

**Alt.**—Alteration of chrysolite often takes place through the oxidation of the iron; the mineral becomes brownish or reddish brown and iridescent. The process may end in leaving the cavity of the crystal filled with limonite or red oxide of iron.

A very common kind of alteration is to the hydrous magnesium silicate, serpentine, with the partial removal of the iron or its separation in the form of grains of magnetite, also as iron sesquioxide; this change has often taken place on a large scale. See further under serpentine, p. 671. A change to anthophyllite and to actinolite has been noted (Becke). Deposits of a hydrous nickel silicate, near genthite, in Douglas Co., Oregon, are shown by Clarke to be probably derived from a nickeliferous chrysolite (anal. 3); a similar occurrence has been noted in North Carolina. See genthite. Chrysolite also occurs altered to amphibole, under certain conditions, in the older crystalline rocks, a zone of which with fibers normal to the outline surrounds a nucleus of the original mineral. Becke has given the name *pilite* to needles of colorless amphibole formed from chrysolite and enclosing also some serpentine, chlorite, magnetite, etc., Min. Mitth., **5**, 164, 1882.

*Limbilite*, *chusite*, and *sideroclepte* of Saussure (J. Phys., 341, 1794), all from Limburg in the Kaiserstuhl, Breisgau, have been regarded as chrysolite more or less altered, but this is doubtful. Cf. Rosenbusch, Jb. Min., 169, 1872.

**Artif.**—Chrysolite and the related minerals of the group have often been observed in slags, cf. Mlr., Min., 319, 1852, also Lasp., Zs. Kr., **7**, 494, 1883 (literature given); Meunier, C. R., **93**, 737, 1881, and especially Vogt, Ak. H. Stockh., Bih., **9** (1), 45, 1884, Arch. Math. Nat., **30**, 8, 1889.

VILLARSITE *Dufrenoy*, C. R., **14**, 697, 1842, Ann. Mines, **1**, 387, 1842. Serpentin aus d. Malenkerthal *Fellenberg*, J. pr. Ch., **101**, 38, 1867.

An altered chrysolite, occurring in pseudomorphous crystals, often trillings, also in rounded grains. Analyses.—1, 2, Dufrenoy, l. c., and Min., **4**, 343, 1859. 3, Fellenberg, l. c.

| | | $SiO_2$ | FeO | MnO | MgO | CaO | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. Traversella | G. = 2·975 | 39·61 | 3·59 | 2·42 | 47·37 | 0·53 | 0·46 | 5·80 | = 99·78 |
| 2. Forez | | 40·52 | 6·25 | — | 43·75 | 1·70 | 0·72 | 6·21 | = 99·15 |
| 3. Malenkerthal | G. = 2·99 | $\frac{2}{2}$ 41·72 | 7·96 | — | 42·15 | — | — | 5·55 | CrO NiO 0·75, [$Al_2O_3$ 3·19 = 101·30 |

Anal. 1 is of the original villarsite from Traversella, where it is associated with mica, quartz, and dodecahedral magnetite; 2, of grains from the granite of Forez and Morvan, France. Grains in the interior of the serpentine pseudomorphs of Snarum have sometimes a similar composition. The mineral from Pirlo in the Malenkerthal, of the Grisons, constitutes the base of a serpentine-like rock, which is slightly crystalline in texture, somewhat slaty, feeble luster, and between blackish gray and dark green in color.

On the optical properties of villarsite see Dx., Min., **1**, 95, 1862, and Lcx., Bull. Soc. Min., **10**, 144, 1887. Named after the mineralogist, Villars, who published a Natural History of Dauphiny.

MATRICITE *N. O. Holst*, G. För. Förh., **2**, 528, 1875. In crystalline masses with concentric, fine fibrous structure. Fracture splintery to uneven. Feel greasy. H. = 3–4. G. = 2·53. Luster pearly. Color gray, often with a greenish tinge. Streak white. Subtranslucent to opaque. Analysis (after the deduction of 28·36 p. c. $CaCO_3$ mechanically mixed):

| $SiO_2$ | MgO | CaO | $Al_2O_3$ | FeO | MnO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 33·99 | 37·96 | 5·64 | 1·33 | 1·82 | 0·47 | 0·98 | 17·81 | = 100 |

B.B. infusible. Yields water in the closed tube. Decomposed by acids with separation of silica, but does not gelatinize. Occurs intimately mixed with calcite and associated with spodiosite, at the Krangrufva in Wermland, Sweden.

FERRITE *Wallace Young*, quoted by Heddle, Min. Mag., **5**, 28, 1882. *Heddle*, ibid., and **7**, 134, 1887. An alteration product of chrysolite in the doleryte between Gleniffar and Boyleston near Glasgow, Scotland. It retains the form in some cases, is soft, deep red to chocolate-brown in color, with cleavage prominent ‖ *a* and *b*. Analysis, Heddle, of the air-dried mineral (loss at 100°, 3·83 p. c.): $SiO_2$ 13·02, $Al_2O_3$ 13·16, $Fe_2O_3$ 53·47, FeO 4·51, MnO 0·15, MgO 6·63, CaO 0·75, $H_2O$ 8·39 = 100·08.

376A. **Hortonolite** *G. J. Brush*, Am. J. Sc., **48**, 17, 1869, *John M. Blake*, ibid., p. 20. In crystals and crystalline masses. Forms: *b* (010, *i*-ĭ), *c* (001, *O*), *m* (110, *I*); *d* (101, 1-ĭ): *k* (021, 2-ĭ); *e* (111, 1), *g* (212, 1-$\bar{2}$). Crystals flattened ‖ *b*, with *d* prominent. Measured angles; *bm* = 65°, ∴ *mm‴* = 50°; *bk* = 40° 45′, ∴ *kk′* = 98° 30′ Blake.

Cleavage: *a* (100), *c* (001). Fracture uneven. H. = 6·5. G. = 3·91. Luster vitreous to resinous. Color yellow to dark yellowish green on the fresh fracture, but black and dull on the surface. Translucent.

Composition, $(Fe,Mg)_2SiO_4$, or intermediate between chrysolite and fayalite, but containing also manganese and hence near some knebelite, p. 457. Anal.—G. J. Brush, l. c., on material purified by an electro-magnet.

$SiO_2$ 33·59, FeO 44·37, MnO 4·35, MgO 16·68, CaO *tr.*, $K_2O$ 0·39, ign. 0·26 = 99·64

B.B. fuses at 4. Reacts for iron and manganese with the fluxes. Decomposed by hydrochloric acid with gelatinization.

Occurs intimately associated with magnetite, also embedded in calcite at an iron mine at Monroe, Orange Co., N. Y. It is named after Mr. Silas R. Horton.

NEOCHRYSOLITE *A. Scacchi*, Rend. Accad. Napoli, Oct. 14, 1876. In small, black, crystalline plates ‖ *b*, also thick tabular ‖ *a*, crystallographically identical with chrysolite. Cf. E. Scc., Zs. Kr., **15**, 293, 1889. Peculiar in containing a considerable amount of manganese, but not yet analyzed. Found in the cavities of the lava of 1631, with sodalite and orthoclase, at the Cupa di Sabataniello, Vesuvius.

376B. **Titan-Olivine** *Damour*, Bull. Soc. Min., **2**, 15, 1879. Péridot titanifère *Id.*, Ann. Mines, **8**, 90, 1855. A variety of chrysolite characterized chemically by the presence of titanium, and physically by its deep yellow or red color and strong pleochroism. Occurs in imperfect crystals or grains, having the angles of ordinary chrysolite, but showing some unusual and uncertain forms, Dx. (Min., **1**, 35, 1862). Sections ⊥ Bx (= 𝔞) show twinning, sometimes polysynthetic with 𝔟 inclined 20° to the trace of the twinning plane symmetrically in each half. Indices: $\alpha = 1{\cdot}669$, $\beta = 1{\cdot}678$, $\gamma = 1{\cdot}702$, $2H_{a.y} = 72° 20'$. $\therefore$ $2V_y = 62° 18'$. Color brownish red. Pleochroism strong: 𝔠 (= 𝔟) bright yellow, 𝔞 deep reddish yellow. Absorption 𝔞 > 𝔟 = 𝔠. It is suggested that the form may be monoclinic similar to clinohumite, to which it bears a certain resemblance, but it is more probably like ordinary chrysolite. Cf. Lcx., who gives the above optical determinations, Bull. Soc. Min., **13**, 15, 1890.

Analyses.—1, 2, Dmr., Ann. Mines, **8**, 90, 1855. 3, Id., Bull. Soc. Min., **2**, 15 1879.

1, Obsidian Cliff; 2, Lake of the Woods, Yellowstone Park, Pfd. 3, Lipari, Id.

In minute crystals, tabular ∥ *a*. Also massive.

Cleavage: *b* distinct, *a* less so. Fracture imperfectly conchoidal. Brittle. H. = 6·5. G. = 4–4·14; 4·138 Fayal; 4·006 Ireland, Delesse. Luster metalloidal, somewhat resinous on the fracture. Color of crystals light yellow, transparent; becoming opaque and dark brown to black and often iridescent on the surface by oxidation. Ax. pl. ∥ *c*. Bx ⊥ *a*.

**Comp.**—Ferrous orthosilicate, $Fe_2SiO_4$ or $2FeO.SiO_2$ = Silica 29·4, iron protoxide 70·6 = 100.

**Anal.**—1, Rg., Min. Ch., 425, 1875. 2, Delesse, Bull. G. Fr., **10**, 571, 1853. 3, Gooch, Am. J. Sc., **30**, 58, 1885. Also 5th Ed., p. 259.

| | $SiO_2$ | FeO | MnO | MgO | CaO | |
|---|---|---|---|---|---|---|
| 1. Fayal | 29·25 | 66·01 | | — | 0·45 | CuO 1·33, $Al_2O_3$ 3·57 = 100·61 |
| 2. Slavcarrach G. = 3·885 | 29·50 | 63·54 | 5·07 | 0·30 | — | = 98·41 |
| 3. Yellowstone | 32·41 | 65·49 | 2·10 | — | — | = 100 |

The crystals analyzed by Gooch were coated with iron oxide; 14·92 $Fe_2O_3$, 7·02 quartz have been deducted and the analysis calculated to 100.

**Pyr., etc.**—Fuses readily to a black magnetic globule. Gelatinizes with acids

**Obs.**—From the Mourne Mts., Ireland, on Slavcarrach, near Bryansford, in pegmatyte; forms nodules in volcanic rocks at Fayal, one of the Azores.

In lithophyses in rhyolite at Obsidian Cliff and other localities in the Yellowstone Park with quartz and a glassy feldspar (anorthoclase, anal. 17, p. 325)[3]; similarly in the obsidian of Lipari (Iddings and Penfield, Am. J. Sc., **40**. 75, 1890). Probably also in similar association in the obsidian of the Cerro de las Navajas, Mexico (Rose, Pogg., **10**, 323, 1827; Iddings, l. c.). Also from Colorado at Cheyenne Mt. Probably with the hafnefiordite of Iceland.[2]

**Artif.**—Crystalline slags having the composition of fayalite are not uncommon. See references under chrysolite, p. 454, also ref. [1] below; further Bull. Soc. Min., **7**, 61, 1884.

Among the various artificial chrysolites is also one having the composition $(Ca,Fe)_2SiO_4$. Vogt (ref. on p. 454) describes crystals, and an analysis by Kruhs gave: $SiO_2$ 34·30, FeO 25·64, CaO 33·72, MnO 0·86, MgO 4·68, $Al_2O_3$ 0·78 = 99·98. Cf. Jackson, Am. J. Sc., **19**, 358, 1855.

**Ref.**—[1] Yellowstone Park, Am. J. Sc., **30**, 59, 1885. Cf. Bauer, Jb. Min., **1**, 1, 1887. [2] Iceland, Dx., Min., **2**, p. x, 1874. [3] Iddings, Obsidian Cliff, 7th Ann. Rep., U. S. G. Surv., p. 270, 1888.

**378 KNEBELITE.** Knebelit *Döbereiner*, Schw. J., **21**, 49, 1817. Igelströmit *Weibull*, G. För. Förh., **6**, 500, 1883; Eisenknebelit *Id.*, Min. Mitth., **7**. 120. 1885.

Orthorhombic. Usually crystalline massive.

Cleavage: *m* distinct; *a*, *c* indistinct. Fracture subconchoidal to uneven. Brittle. H. = 6·5. G. = 3·9–4·17; 4·122 Erdmann. Luster glistening, greasy. Color gray, spotted dirty-white, red, brown, yellow, and green; also grayish black to black. Translucent to opaque.

Optically −. Ax. pl. ∥ $c$. Bx ⊥ $a$. Dispersion $\rho > v$. Ax. angle = 63° 45′ (in glass) Dx. For igelströmite 59° 12′ Weibull.

**Comp.**—$(Fe,Mn,Mg)_2SiO_4$ or $2(Fe,Mn,Mg)O.SiO_2$. The relation between the iron, manganese and magnesium varies widely.

**Var.**—1. *Ordinary.* Ratio of Fe : Mn nearly = 1 : 1, which requires: Silica 29·6, iron protoxide 35·5, manganese protoxide 34·9 = 100. In crystalline masses, showing cleavage.

2. *Igelströmite. Eisenknebelit.* Contains about 10 p. c. more FeO and less MnO than ordinary knebelite. A variety (anal. 5) from the rock called eulysyte contains still more iron, and approximates toward hortonolite (p. 455) and hyalosiderite (p. 452).

**Anal.**—1, Pisani, Dx. Min., **2**, p. xi, 1874. 2. Weibull. Min. Mitth., **7**, 121, 1885. 3, Id., G. För. Förh., **6**, 500, 1883. 4, Id., ibid., **7**, 263, 1884. 5, Erdmann, Öfv. Ak. Stockh., **6**, 111, 1849.

**Pyr.**, **etc.**—According to Döbereiner, unaltered B.B., but Erdmann's mineral fused easily to a lusterless magnetic bead, and gave with the fluxes reactions for iron and manganese. Decomposed readily by hydrochloric acid with separation of gelatinous silica.

**Obs.**—The original mineral analyzed by Döbereiner was from an unknown locality, but G. Suckow (Kenng., Ueb. Min., 93, 1855) states, on the authority of Knebel, that it was found in granite near Ilmenau. The Dannemora mineral is grayish black to black in large masses, light gray on the thin edges, and is stated to cleave parallel to a prism of about 65°. Also from the Vester-Silfberg mine in the Norrbärke parish, Dalekarlia, and the Hillängs mine, 4 miles to the southwest.

Erdmann's mineral was from the chrysolitic rock called by him eulysyte from the region of Tunaberg, Södermanland, Sweden; it was dark yellow to reddish brown in color, and was intimately mingled with diallage and a brown garnet.

Named after Major von Knebel.

**379. TEPHROITE.** Tephroit *Breith*, Char., 278, 1823; 212, 329, 1832. Tefroit *Swed*. Picrotephroite.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·46004 : 1 : 0·59389 Hj. Sjögren[1].

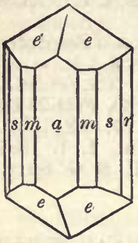
100 ∧ 110 = 24° 42¼′, 001 ∧ 101 = 52° 14¼′, 001 ∧ 011 = 30° 42⅓′.

**Forms**[2]: *a* (100, $i\text{-}\bar{i}$), *x* (10·9·0, $i\text{-}\frac{10}{9}$), *m* (110, $I$), *s* (120, $i\text{-}\breve{2}$), *h* (011, $1\text{-}\breve{i}$), *e* (111, 1), *f* (121, $2\text{-}\breve{2}$). *l* (131, $3\text{-}\breve{3}$).

*mm‴* = 49° 24′ *ae* = *42° 1′ *ee″* = 109° 44′ *ee‴* = 39° 58′
*ss′* = 94° 46′ *ee′* = 95° 58′ *ff″* = 120° 38′ *ff‴* = 72° 4′
*as* = *42° 37′ *ff′* = 79° 29′ *ll″* = 131° 7′ *ll‴* = 94° 59′
*hh′* = 61° 25′ *ll′* = 64° 35′

Crystals rare. Usually crystalline massive.

Cleavage distinct in two directions at right angles. Fracture subconchoidal. Brittle. H.=5·5–6. G.=4–4·12. Luster vitreous to greasy. Color grayish flesh-red, reddish brown, and rose-red, to ash-gray, smoky-gray. Streak pale gray. Darkens on exposure to brown and black. Translucent to subtranslucent.



Pajsberg, Flink.

Pleochroism distinct: $\mathfrak{c}$ (= $\breve{a}$) greenish blue, $\mathfrak{b}$ (= $\breve{c}$) reddish, $\mathfrak{a}$ (= $b$) brownish red. Absorption $\mathfrak{b} > \mathfrak{c} > \mathfrak{a}$. Optically −. Ax. pl. ∥ $c$. Bx ⊥ $b$. Axial angles, Dx. and Flink:

$$2H_{a.r} = 84^\circ\ 41' \quad 2H_{a.bl} = 82^\circ\ 59' \quad \therefore 2E_r = 161^\circ\ 48' \quad 2E_{bl} = 156^\circ\ 35'$$
$$2H_{a.y} = 81^\circ\ 4' \quad 2H_{o.y} = 112^\circ\ 16' \quad \therefore 2V_{a.y} = 76^\circ\ 6'$$

**Comp.**—Manganese orthosilicate, $Mn_2SiO_4$ or $2MnO.SiO_2$ = Silica 29·8, manganese protoxide 70·2 = 100. Magnesium is usually present, and in picrotephroite to considerable amount. Also in small quantity iron, and sometimes zinc, though the zinc may be in part due to zincite (Brush).

**Anal.**—1, G. J. Brush, Am. J. Sc., **37**, 66, 1864 (the original tephroite of Breithaupt). 2, Collier, ibid. 3, Hague, ibid. 4, Mixter, ib., **46**, 231. 1868. 5, G. C. Stone, Sch. **Pyr., etc.**—B.B. fuses at 3·5 to a black scoria. Gelatinizes in hydrochloric acid without evolving chlorine. With the fluxes gives reactions for manganese and iron. The magnesian variety fuses at 4 (anal. 2) to 6 (anal. 3).

**Obs.**—Found at Sterling Hill in the town of Sparta, Sussex Co., N. J., with zincite, willemite, and franklinite, in cleavable masses; at Franklin Furnace in the same region, similarly associated; also at Pajsberg in Wermland, Sweden. along with rhodonite and other manganesian minerals; at the Sjögrufva, with hausmannite; at Långban. Wermland (*picrotephroite*) with jacobsite, diopside, etc.

The name *tephroite* is from *τεφρός, ash-colored.* Breithaupt's original specimen was from the collection of H. Heyer at Dresden.

**Ref.**—[1] Långban, G. För. Förh., **6**, 539, 1883. Flink, Pajsberg, Ak. H. Stockh., Bihang, **13** (2), No. 7, 64, 1888. Flink calculates: $\breve{a} : \bar{b} : \breve{c} := 0{\cdot}4621 : 1 : 0{\cdot}5914$. [2] Dx., Ann. Mines, **2**, 339, 1862, N. R., 99, 1867. Also Flink, l. c.

HYDROTEPHROITE. Hydrotefroit. *L. J. Igelström*, Öfv. Ak. Stockh., **27**, 605, 1865. A hydrous tephroite from Pajsberg, which has a pale reddish color, a colorless streak, and H. = 4; gelatinizes with acids and yields water. Analysis: $SiO_2$ 28·46, $Mn_2O_3$ 0·49, MnO 53·44, MgO 11 89, CaO FeO *tr.*, $H_2O$ 5·85 = 100·13, and corresponding to $(Mn,Mg)_2SiO_4 + \frac{2}{3}H_2O$. It may be an altered tephroite.

EPIGENITE *L. J. Igelström*, G. För. Förh., **11**, 393, 1889. NEOTESITE *Id.*, Jb. Min., **1**, 257, 1890. Near hydrotephroite and apparently also derived from tephroite. Occurs in small bladed masses embedded in tephroite. Cleavage: distinct. H. = 5–5·5. Color brownish red, resembling orthoclase or some rhodonite. Streak pale red. Composition $(Mn,Mg)SiO_4.H_2O$. Analysis: Igelström, l. c.

$SiO_2$ 29·50 MnO 40·60 FeO *tr.* MgO 20·05 $H_2O$ 9·85 = 100

B.B. fuses rather easily to a black bead. Decomposed by acids without gelatinization.

Occurs at the manganese mine, the Sjögrufva, in the Grythytte parish, Örebro, Sweden, immediately associated with gray tephroite, calcite, etc., in an ore carrying hausmannite.

*A black silicate of manganese* from Klapperud, Dalekarlia, having a submetallic luster and yellowish brown streak, afforded Klaproth (Beitr., 4, 137): $SiO_2$ 25·0, MnO 55·8, $H_2O$ 13·0=93·8 = $Mn_2SiO_4 + 2H_2O$, agreeing with the tephroite, excepting the water. Klaproth obtained 60 p. c. of $MnO,Mn_2O_3$, whence the above is deduced by Berzelius.

**379A. Rœpperite.** Iron-manganese-zinc chrysolite *Rœpper*, Am. J. Sc., **50**, 35, 1870. *Rœpperite G. J. Brush*, Dana's Min., App. I, p. 13, 1872. Stirlingite *Kenngott*, Jb. Min., 188, 1872.

Orthorhombic. In large coarse crystals resembling chrysolite, with *a* (100), *b* (010), *c* (001), *m* (110), *d* (101), *k* (021), *e* (111), *ω* (211)?. Angles: *mm‴* = 50°, *dd′* = 103°.

Cleavage: *b*, *c* distinct; *a* splintery. H. = 5·5–6. G. = 3·95–4·08. Luster vitreous to greasy. Color when fresh pale yellow, as weathered dark green to black, mottled. Translucent in thin splinters. Streak yellow to reddish gray. Slightly magnetic.

Composition: $(Fe,Mn,Zn,Mg)_2SiO_4$, and hence near some kinds of tephroite, p. 458. Anal.—1–3, W. T. Rœpper, l. c.

| | $SiO_2$ | FeO | MnO | ZnO | MgO | |
|---|---|---|---|---|---|---|
| 1. *Crystals* | 30·76 | 33·78 | 16·25 | 10·96 | 7·60 | = 99·35 |
| 2. " | 30·23 | 35·52 | 16·91 | 10·68 | 5·63 | insol. 1·04 = 100·01 |
| 3. *Massive* | $\frac{2}{2}$ 30·54 | 34·78 | 17·74 | 9·48 | 6·09 | insol. 2·02 = 100·65 |

B.B. fuses with difficulty on the thin edges to a black slag. With the fluxes reacts for iron, manganese, and silica; on charcoal with soda gives a zinc coating. Gelatinizes with acids readily and completely, leaving sometimes a bright green residue of spinel.

Occurs at Sterling Hill, Sussex Co., N. J., with willemite, franklinite, jeffersonite, and spinel; also found at Franklin Furnace with gahnite.

A zinc chrysolite (Zinkfayalit *Germ.*) has been noted as a furnace product by Stelzner at Freiberg. It occurs in the slags in foliated aggregates of tabular crystals, rectangular in form, together with a zink spinel. An analysis of material consisting chiefly of these aggregates gave: $SiO_2$ 28·45, ZnO 18·55, FeO 41·98, $SnO_2$ 0·75, PbO 2·50, CuO 0·60, CaO 3·00, MgO 0·84, BaO 1·80, $Al_2O_3$ 1·31, S 1·70 = 101·48, deduct (O = S) 0·85 = 100·63. Jb. Min., **1**, 170, 1882.

---

## 6. Phenacite Group. $R_2SiO_4$. Rhombohedral.

**380. Trimerite** $Mn_2SiO_4.Be_2SiO_4$ Pseudo-hexagonal $\dot{c} = 0·7233$

Triclinic $\left\{ \begin{array}{l} \breve{a} : \bar{b} : \dot{c} = 0·5773 : 1 : 0·5425 \\ \alpha = \beta = \gamma = 90° \end{array} \right.$

---

| | | | | $rr'$ | $\dot{c}$ |
|---|---|---|---|---|---|
| **381.** | **Willemite** | $Zn_2SiO_4$ | | 64° 30′ | 0·6775 |
| | Troostite | $(Zn,Mn)_2SiO_4$ | | | |
| **382.** | **Phenacite** | $Be_2SiO_4$ | Tetartohedral | 63° 24′ | 0·6611 |

As shown by Brögger, the pseudo-hexagonal species, Trimerite, connects the Phenacite Group proper with the Chrysolite Group; in composition it is intermediate between Tephroite and Phenacite.

---

| | | | | $rr'$ | $\dot{c}$ |
|---|---|---|---|---|---|
| **383.** | **Dioptase** | $H_2CuSiO_4$ | Tetartohedral | 54° 5′ | 0·5342 |
| **384.** | **Friedelite** | $H_7(MnCl)Mn_4(SiO_4)_4$ | | 56° 17′ | 0·5624 |
| **385.** | **Pyrosmalite** | $H_7((Fe,Mn)Cl)(Fe,Mn)_4(SiO_4)_4$ | | 53° 49′ | 0·5308 |

The three species Dioptase, Friedelite, Pyrosmalite are very near to each other in form, as shown in the above axial ratios; they further approximate closely to the species of the Phenacite Group proper, with which they are further connected by the tetartohedrism of Dioptase.

They are also closely related among themselves in composition, since they are all acid ortho-silicates, and have the general formula $H_2RSiO_4 = H_8R_4(SiO_4)_4$, where (*e.g.* for Friedelite) in the latter form the place of one hydrogen atom is taken by the univalent radical (MnCl).

### 380. TRIMERITE. *G. Flink*, Zs. Kr., 18, 361, 1890.

Triclinic, pseudo-hexagonal. In thick tabular prismatic crystals hexagonal in form and angle. Axis $\dot{c} = 0{\cdot}7233$; $0001 \wedge 10\bar{1}1 = 39° 52'$ Flink[1].

**Forms:** $c$ ($0001$, $O$), $a$ ($11\bar{2}0$, $i$-2); $m$ ($10\bar{1}0$, $I$); $s$ ($33\bar{6}8$, $\frac{3}{4}$-2), $p$ ($33\bar{6}4$, $\frac{3}{2}$-2), $o$ ($12{\cdot}3{\cdot}\bar{15}{\cdot}8$, $\frac{15}{8}$-$\frac{5}{4}$).

Angles: $cs = 28° 29'$, $cp = {}^*47° 20'$, $pp' = 43° 8\frac{1}{2}'$.

The fundamental form assumed above shows the relation to phenacite. If $p$ be made $10\bar{1}1$, the forms, taken in the above order, become: $c$ ($0001$), $m$ ($10\bar{1}0$), $a$ ($11\bar{2}0$), $s$ ($10\bar{1}2$), $p$ ($10\bar{1}1$), $o$ ($21\bar{3}2$). The pyramid $o$ is present according to pyramidal hemihedrism.

Optically trimerite is shown by Brögger[2] to be triclinic with a prismatic angle of 60°. On this basis (if $m = 110$, $p = 111$) the axial ratio is $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}57735 : 1 : 0{\cdot}54248$; $\alpha=\beta=\gamma=90°$. See further the optical relations (Bgr.) explained below.

Cleavage: basal, distinct. Fracture conchoidal. Brittle. H.=6–7. G.=3·474 Bgr. Luster vitreous, brilliant. Color salmon-pink, pale yellowish red to nearly colorless in small crystals. Transparent to translucent.

A basal section shows strong double refraction, with composition of three individuals, the position of each corresponding to a revolution of 120° about the normal to the basal plane. There are also embedded lamellæ parallel in position. The ax. pl. is inclined 20° to the adjacent edge $c/m$. The ax. plane and $Bx_a$ are nearly $\perp c$, but in the lamellæ, seen also in sections ∥ $a$ ($11\bar{2}0$), a variation of 2½° on one side to 4° on the other is noted. Optical character $-$. Refractive indices:

| | | |
|---|---|---|
| $\alpha_r = 1{\cdot}7119$ Li | $\beta_r = \frac{2}{2}\,1{\cdot}7173$ | $\gamma_r = 1{\cdot}7220$ |
| $\alpha_y = 1{\cdot}7148$ Na | $\beta_y = \frac{2}{2}\,1{\cdot}7202$ | $\gamma_y = 1{\cdot}7253$ |
| $\alpha_{gr} = 1{\cdot}7196$ Tl | $\beta_{gr} = \frac{2}{2}\,1{\cdot}7254$ | $\gamma_{gr} = 1{\cdot}7290$ |
| $2H_{a.y} = 101° 12'$ | $2H_{o.y} = 120° 1'$ | $2V_y = 83° 29'$ |

**Comp.**—$(Mn,Ca)_2SiO_4.Be_2SiO_4$. If Mn : Ca = 2 : 1, the percentage composition is: Silica 39·8, glucina 16·6, manganese protoxide 31·3, lime 12·3 = 100. Iron also replaces part of the manganese.

**Anal.**—Flink, l. c.

$SiO_2$ 39·77 BeO 17·08 MnO 26·86 FeO 3·87 CaO 12·44 MgO 0·61 = 100·63

**Pyr.**—B.B. fusible with difficulty in thin splinters forming a black slag: gives the usual reactions for manganese and iron. Very slightly attacked by dilute hydrochloric acid, but readily decomposed by strong acid when pulverized, with the separation of flocculent silica.

**Obs.**—Of rare occurrence at the Harstig mine, Wermland, Sweden; it is found embedded in calcite; the crystals, sometimes coated with a web of actinolite needles, are implanted upon a rock consisting of a fine granular mixture of magnetite, grayish green pyroxene, garnet, etc. The largest crystal found was 12 mm. broad and 8 mm. thick.

Named from τριμερής, *in three parts*, in allusion to its optical structure.

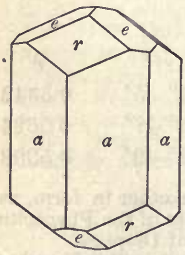
**Ref.**—[1] L. c. [2] Ibid., p. 371 and 377.

---

### 381. WILLEMITE. Siliceous Oxide of Zinc, Silicate of Zinc (fr. N. Jersey), *Vanuxem & Keating*, J. Ac. Philad., 4, 8, 1824. Willemite (fr. Moresnet) *Lévy*, Jb. Min., 71, 1830; Ann. Mines, 4, 513, 1843. Williamsite, Wilhelmite, Villemite, *alt. orthogr.* Anhydrous Silicate of Zinc. Hebetin (fr. Moresnet) *Breith.*, Char., 130, 1832. Troostite (fr. N. J.) *Shepard*, Min., 1st part, 154, 1832. Tephrowillemite *Koenig*, Proc. Ac. Philad., 187, 1889.

Rhombohedral. Axis $\dot{c} = 0{\cdot}6775$; $0001 \wedge 10\bar{1}1 = 38° 2\frac{1}{6}'$ E. S. D.[1]

1.



New Jersey.

**Forms**[2]**:** Moresnet $c$ ($0001$. $O$), $m$ ($10\bar{1}0$, $I$), $p$ ($30\bar{3}4$, $\frac{3}{4}$); for N. Jersey $a$ ($11\bar{2}0$, $i$-2), $r$ ($10\bar{1}1$, $R$), $e$ ($01\bar{1}2$, $-\frac{1}{2}$), $x$ ($21\bar{3}1$, $,1^3$).

| | | | |
|---|---|---|---|
| $cp = 30° 24'$ | $pp' = 51° 59'$ | $ax = 27° 51'$ | $ae'' = 90° 0'$ |
| $cr = 38° 2'$ | $rr' = {}^*64° 30'$ | $ar = 57° 45'$ | $mx = 29° 54'$ |
| $ce = 21° 22'$ | $ee' = 36° 47'$ | | |

In hexagonal prisms, sometimes long and slender, again short and stout. Also massive and in disseminated grains; fibrous.

Cleavage: $c$ easy, Moresnet; difficult, N. J.; $a$ easy, N. J. Fracture conchoidal to uneven. Brittle. H.= 5·5. G.= 3·89–4·18. Luster vitreo-resinous, rather weak. Color white or greenish yellow, when purest; apple-green, flesh-red, grayish white, yellowish brown; often dark brown when impure. Streak uncolored. Transparent to opaque. Optically +. Double refraction strong.

**Var.**—The crystals of Moresnet and New Jersey differ in occurring forms as above described. The latter are often quite large, of flesh-red or gray color, opaque, and pass under the name of *troostite;* they commonly contain manganese in considerable amount; this is also true of the clear honey-yellow or apple-green crystals in the form of slender hexagonal prisms, and further of the massive forms. *Tephrowillemite* is simply a kind of troostite, anal. 13; it has a brownish-gray color.

A white granular variety from the Trotter mine, Franklin, is nearly pure zinc silicate Clarke obtained: $SiO_2$ 27·41, ZnO 68·86, MnO (FeO) undet., ign. 0·25 = 96·52, Bull. **60**, U. S. G. Surv., p. 130.

**Comp.**—Zinc orthosilicate, $Zn_2SiO_4$ or $2ZnO.SiO_2$ = Silica 27·0, zinc oxide 73·0 = 100. Manganese often replaces a considerable part of the zinc, and iron is also present in small amount.

**Pyr., etc.**—B.B. in the forceps glows and fuses with difficulty to a white enamel; the varieties from New Jersey fuse from 3·5 to 4. The powdered mineral on charcoal in R.F. gives a coating, yellow while hot and white on cooling, which, moistened with solution of cobalt, and treated in O.F., is colored bright green. With soda the coating is more readily obtained. Decomposed by hydrochloric acid with separation of gelatinous silica. The N. J. variety phosphoresces with a green light when in the dark after being struck with a hammer.

**Obs.**—From Altenberg near Moresnet, between Liège and Aix-la-Chapelle, in crystals and massive, the crystals but a few millimeters in length; also at Stolberg, near Aix-la-Chapelle; at Musartut, Tunugdliarfik, in Greenland. In New Jersey at Mine Hill, Franklin Furnace, and at Sterling Hill near Ogdensburg, two miles distant, in such quantity as to constitute an important ore of zinc. It occurs intimately mixed with zincite and franklinite, and is found massive of a great variety of colors, from white to pale honey-yellow and light green to dark ash-gray and flesh-red; sometimes in reddish crystals (*troostite*) six inches long and an inch or more thick, embedded in franklinite and also in calcite; rarely in slender transparent prisms of a delicate apple-green color. Rare at the Merritt mine, Socorro Co., New Mexico, with mimetite, wulfenite, etc.

Named by Lévy after William I., King of the Netherlands.

**Artif.**—Obtained crystallized by Gorgeu (Bull. Soc. Min., **10**, 38, 1887) by heating one part of hydrated silica with 30 parts of an intimate mixture of sodium sulphate and $\frac{1}{2}$ to 1 equivalent of zinc sulphate. The fused mass treated in boiling water left characteristic hexagonal crystals with G. = 4·25 and consisting of: $SiO_2$ 26·4, ZnO 73·6.

Observed in furnace slag obtained from lead ores carrying zinc, in minute bright yellow crystals; the mass of the slag consisted of ferrous orthosilicate, fayalite. See Hutchings, Geol. Mag., **7**, 31, 1890. Cf. also Schulze and Stelzner, who describe the occurrence of a hexagonal zinc silicate in slender prismatic crystals, or radiating aggregates embedded in a semi-crystalline ground-mass with zinc spinel and tridymite. Jb. Min., **1**, 150, 1881.

**Ref.**—[1] Franklin Furnace willemite, contact goniometer; Lévy gives $pp' = 51° 30'$. [2] Cf. Dx., Min., **1**, 43, 1862, he adds $03\bar{3}2$ deduced from Breithaupt's figure (Min., **3**, 478, 1847), which is like fig. 1, and probably gives *r* above. Arzruni describes supposed twins from Altenberg with tw. pl. $\frac{3}{5}$-2 $(3 \cdot 3 \cdot \breve{6} \cdot 10)$, Pogg., **152**, 281, 1874.

**382. PHENACITE.** Phenakit *N. v. Nordenskiöld*, Ak. H. Stockh., 160, 1833, Pogg., **31**, 57, 1834.

Rhombohedral; tetartohedral. Axis $\dot{c} = 0{\cdot}66107$; $0001 \wedge 10\bar{1}1 = 37° 21' 21''$ Rose–Koksharov[1].

**Pyr., etc.**—Alone remains unaltered; with borax fuses with extreme slowness, unless pulverized, to a transparent glass. With soda affords a white enamel; with more, intumesces and becomes infusible. Dull blue with cobalt solution.

**Obs.**—Occurs (in prismatic crystals) in mica schist at the emerald and chrysoberyl mine of Takovaya, 85 versts E. of Ekaterinburg, where the crystals are sometimes nearly 4 inches across, and one found weighs 1½ lbs.; also in small rhombohedral crystals on the east side of the Ilmen Mts., 5 versts N. of Miask, with topaz and green feldspar; also in highly modified crystals with quartz, in limonite, near Framont in the Vosges Mts.; in Switzerland with hematite at Reckingen in the Valais, with adularia, hematite (Eisenrosen), quartz. Also at the Cerro del Mercado, Durango, Mexico; part of the so-called phenacite from here is only apatite, but the occurrence has been recently substantiated by Khrushchov (anal. 3); according to him the crystals occur in a quartz porphyry and also loose embedded in clay.

In Colorado, in flat rhombohedral crystals with topaz on amazonstone, also embedded in it, at Topaz Butte, near Florissant, 16 miles from Pike's Peak; also in crystals often prismatic and sometimes an inch across on quartz and beryl at Mt. Antero, Chaffee County. In New Hampshire, in lenticular crystals with topaz on Bald Face Mt., North Chatham, a few miles west of Stoneham, Me. (Kunz). Also reported as occurring at the mica mines of Amelia Court House, Virginia (Yeates).

Named from φέναξ, *a deceiver*, in allusion to its having been mistaken for quartz.

**Artif.**—Obtained by Ebelmen in minute hexagonal prisms by fusion of $SiO_2$ and BeO with borax, cf. Mld., C. R., **105**, 1260, 1887.

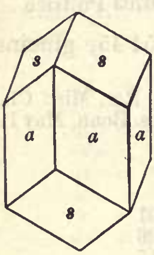
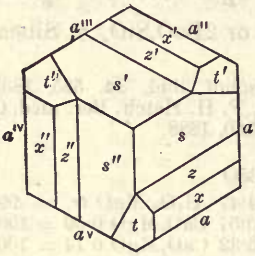
Twins[7]: tw. pl. *r*, as geniculated twins. Commonly in prismatic crystals, *a*, with *s* (02$\bar{2}$1), fig. 1. Faces in zone *a s* striated ‖ edge *a*/*s*. The hemi-scalenohedrons, or rhombohedrons of the third series, sometimes characteristically developed as on the edge *a s* (f. 2), but often indistinctly indicated. Also indistinct crystalline aggregates; massive.

Cleavage: *r* perfect. Fracture conchoidal to uneven. Brittle. H. = 5. G. = 3·28–3·35. Luster vitreous. Color emerald-green. Streak green. Transparent to subtranslucent. Optically positive. Double refraction strong. Refractive indices: $\omega = 1·667$, $\epsilon = 1·723$ Mlr.[8] Pyroelectric.

1.



2.



**Comp.**—$H_2CuSiO_4$ or $H_2O.CuO.SiO_2$ = Silica 38·2, cupric oxide 50·4, water 11·4 = 100. Loses water only at a red heat, the hydrogen consequently basic (Rg.).

Tschermak writes the formula $(CuOH)HSiO_3$.

**Anal.**—1, 2, Damour, Ann. Ch. Phys., **10**, 485, 1844; earlier Hess, Pogg., **16**, 360, 1829.

| | $SiO_2$ | CuO | $H_2O$ |
|---|---|---|---|
| 1. | 36·47 | 50·10 | 11·40 $Fe_2O_3$ 0·42, $CaCO_3$ 0·35 = 98·74 |
| 2. | 38·93 | 49·51 | 11·27 = 99·71 |

Groth assumes that chrysocolla is merely dioptase mingled with amorphous silica and other impurities. There seems little doubt, however, notwithstanding the impurity of much of the material analyzed, that chrysocolla deserves to be recognized as a definite hydrous species chiefly amorphous in structure. See further p. 699.

**Pyr., etc.**—In the closed tube blackens and yields water. B.B. decrepitates, colors the flame emerald-green, but is infusible. With the fluxes gives the reactions for copper. With soda and charcoal a globule of metallic copper. Gelatinizes with hydrochloric acid.

**Obs.**—Dioptase occurs in druses of well defined crystals on quartz, occupying seams in a compact limestone west of the hill of Altyn-Tübe in the Kirghese Steppes. In the gold washings at several points in Siberia, as on the R. Malaya in Transbaikal. At Rezbánya, Hungary on a bluish clay, or on wulfenite and calamine. From Copiapo, Chili, on quartz with other copper ores, also on limonite, crystals terminated by *r* (Rath), also crusts. G. = 3·325 Bauer. In fine crystals at the Mine Mindouli, two leagues east of Comba, between Bouanza and Brazzaville in the French Congo State, associated with hyaline silica and chrysocolla (Jannettaz, Bull. Soc. Min., **13**, 159, 1890).

At the copper mines of Clifton, Graham Co., Arizona, in brilliant crystals lining cavities in "mahogany ore" consisting of limonite and copper oxide; also 100 miles west, near Riverside P. O., Pinal Co.

Named by Haüy *dioptase*, from *διά, through*, and *ὄπτομαι, to see*, because the cleavage directions were distinguishable on looking through the crystal.

Named *Achirite* after Achir Mahméd, a Bucharian merchant, living at the fortress of Semipalatinsk, who had procured it in the region where it occurred, and who furnished the specimens that were taken in 1785 by Mr. Bogdanov to St. Petersburg. Although first named by Hermann, his description was not given to the St. Petersburg Academy before 1800, and the volume containing it was not published until 1802, a year after the appearance of Haüy's work.

**Ref.**—[1] Breith., Schweigg. J., **62**, 221, 1831, confirmed by Koksharov, Min., **6**, 285, 1870, both on cleavage forms. [2] Haüy, l. c., 1801. [3] Breith., l. c., he gives for *o*, $-\frac{12}{7}^{\frac{10}{9}}$ (*so* = 2° 52′), for *u*, $-2^{\frac{7}{8}}$ (*su* = 3° 22′), which symbols do not agree with the angles; the symbols given above were calculated by Websky. Kenngott suggests others slightly different.

[4] Lévy, Heuland, **3**, 92, 1837. [5] Credner. Jb. Min., 404, 1839; he gives no angles. [6] Websky Pogg., **69**. 543, 1846; corrects Breithaupt. [7] Kenng., Min. Unt., 93, 1850; review of preceding, the position of *k*, *g*, *l*, is uncertain; ξ may be the same as Websky's doubtful *v*; see, too, Hausm. Handb.. **2**, 746, 1847; *α*, *β* were observed as complete scalenohedrons. [8] Mlr., Phil. Mag., **21**, 278, 1842.

**384. FRIEDELITE.** *Bertrand*, C. R., **82**, 1167, 1876; Zs. Kryst., **1**, 86, 1877.

Rhombohedral. Axis $\dot{c} = 0·5624$; $0001 \wedge 10\bar{1}1 = {}^*33°$ Bertrand.

**Forms:** *c* (0001, *O*), *m* ($10\bar{1}0$, *I*). *r* ($10\bar{1}1$, *R*). Angles: *cr* = 33°, *rr′* = 56° 17′.

Crystals commonly tabular ‖ *c*; faces *m*, *r* often striated ‖ edge *m*/*r*. Also massive, with saccharoidal structure and distinct cleavage, passing into close compact forms with indistinct cleavage.

Cleavage: *c* perfect. H. = 4–5. G. = 3·07. Color rose-red. Powder pale rose. Transparent to translucent. Optically −. Double refraction strong.

**Comp.**—$H_7(MnCl)Mn_4Si_4O_{16}$ as written by Groth. Percentage composition: Silica 35·1, manganese protoxide 51·7 (or MnO 46·5, Mn 4·0), chlorine 5·2, water 9·2 = 101·2, deduct (O = 2Cl) 1·2 = 100.

**Anal.**—Gorgeu, Bull. Soc. Min., **7**, 3, 58, 1884.

$SiO_2$ 34·45 MnO 48·25 MgO 1·20 CaO 0·40 Mn 2·60 Cl 3·40 $H_2O$ 9·60 = 99·90

In an earlier analysis by Bertrand (l. c.) the chlorine was overlooked. The material used by Gorgeu was not entirely pure. Cf. Friedel, ib., p. 71.

**Pyr.**—B.B. fuses easily to a black glass. Gives off water in the closed tube on strong ignition. Reaction for manganese with the fluxes. Dissolves in hydrochloric acid, forming a jelly.

**Obs.**—Associated with rhodochrosite and alabandite at the manganese mine of Adervielle, vallée du Louron, Hautes Pyrénées. Named after the French chemist and mineralogist Ch. Friedel. See also p. 1035.

**385. PYROSMALITE.** Pirodmalit *Hausm.*, Moll's Efem., **4**, 390, 1808. Wesentlicher Bestandtheil Salzsaures Eisenoxyd, *id.*, ib. (fr. blowpipe trials of Gahn, its discoverer). Pyrosmalit *Karst.*, Tab., 103, 1808; *Hausm.*, Handb., 1068, 1813. Fer muriaté *H.*, 1812, Lucas Tabl., **2**, 418, 1813.

Rhombohedral. Axis $\dot{c} = 0·5308$; $0001 \wedge 10\bar{1}1 = 31°\ 30\tfrac{1}{4}'$ A. E. Nordenskiöld[1].

**Forms:** *c* (0001, *O*); *m* ($10\bar{1}0$, *I*); *r* ($10\bar{1}1$, 1), *z* ($01\bar{1}1$, − 1); *σ* ($20\bar{2}1$, 2), *s* ($02\bar{2}1$, − 2).

Angles: *cr* = 31° 30′, *cσ* = 50° 48′, *mr* = 58° 30′, *rr′* = 53° 49′, *rz* = 30° 17½′, *σs* = 45° 35, *σσ′* = 84° 18′.

Crystals thick prismatic or tabular in habit, usually with *m*, *r*, *z*, hence apparently hexagonal. Also massive, foliated.

Cleavage: *c* perfect; *m* imperfect. Fracture uneven, rather splintery. Somewhat brittle. H. = 4–4·5. G. = 3·06–3·19. Luster of *c* pearly; of other planes, less so. Color blackish green to pale liver-brown, passing into gray and pistachio-green; usually brown externally, and light greenish yellow internally. Streak paler than color. Optically −. Double refraction strong.

**Comp.**—$H_7((Fe,Mn)Cl)(Fe,Mn)_4Si_4O_{16}$ = Silica 34·9, iron protoxide 26·2, manganese protoxide 25·8, chlorine 5·1, water 9·2 = 101·2, deduct (O = 2Cl) 1·2 = 100. Here Fe : Mn = 1 : 1.

**Anal.**—1, Lang, J. pr. Ch., **83**, 424, 1861. Also Wöhler, Lieb. Ann., **156**, 85, 1870. 2, Ludwig, Min. Mitth., 211, 1875. 3, Engström, G. För. Förh., **3**, 116, 1876. 4, Gorgeu, Bull. Soc. Min., **7**, 58, 1884.

| | | | $SiO_2$ | FeO | MnO | CaO | MgO | $H_2O$ | Cl | | |

[a] $Fe_2O_3$ 2·92.

**Pyr., etc.**—In the closed tube yields water, which reacts acid. B.B. fuses at 2–2·5 to a black magnetic glass. With the fluxes gives reactions for iron and manganese. A bead of salt of phosphorus, previously saturated with oxide of copper, when fused with the pulverized mineral imparts a beautiful azure color to the flame (chlorine). Decomposed by hydrochloric acid, with separation of silica.

**Obs.**—Pyrosmalite occurs at Bjelkegruva, one of the iron mines of Nordmark in Wermland, Sweden, where it is associated with calcite, pyroxene, apophyllite, and magnetite. A hexagonal prism, in the museum at Stockholm, is nearly an inch in diameter and one and a quarter inches long, and weighs five and a half ounces. Also from the Kogrufva in Nordmark and at the iron mines at Dannemora in foliated masses with a green pyroxene.

Named from πῦρ, *fire*, ὀσμή, *odor*, in allusion to the odor when heated.

**Ref.**—Öfv. Ak. Stockh., **27**, 562, 1870. The rhombohedral character of the crystals may be assumed on the basis of the isomorphism with friedelite.

## 7. Scapolite Group. Tetragonal.

| | | |
|---|---|---|
| 386. | **Meionite** | ċ = 0·4393 |
| 387. | **Wernerite** | ċ = 0·4384 |
| 388. | **Mizzonite** | ċ = 0·4424 |
| | Dipyre | |
| 389. | **Marialite** | ċ = 0·4417 |

---

| | | |
|---|---|---|
| 390. | **Sarcolite** | ½ċ = 0·4437 |

The species of the SCAPOLITE GROUP are tetragonal in crystallization, with nearly the same axial ratio, and further they are characterized by pyramidal hemihedrism. They are white or grayish white in color, except when impure, and then rarely of dark color. Hardness = 5–6·5; G. = 2·5–2·8. In composition they are silicates of aluminium with calcium and sodium in varying amounts; chlorine is also often present, sometimes only in traces. Iron, magnesia, potash are not present unless by reason of inclusions or of alteration, which last cause also explains the carbon dioxide often found in analysis.

The Scapolites are analogous to the Feldspars in that they form a series with a gradual variation in composition, the amount of silica increasing with the increase of the alkali, soda, being 40 p. c. in meionite and 64 p. c. in marialite. A corresponding increase is observed also in the amount of chlorine present. Furthermore there is also a gradual change in specific gravity, in the strength of the double refraction, and in resistance to acids, from the easily decomposed meionite, with G. = 2·72, to marialite, which is only slightly attacked and has G. = 2·63.

Tschermak[1] has shown that the variation in composition may be explained by the assumption of two fundamental end compounds, viz.:

| | | |
|---|---|---|
| Meionite | $Ca_4Al_6Si_6O_{25}$ | Me |
| Marialite | $Na_4Al_3Si_9O_{24}Cl$ | Ma |

By the isomorphous combination of these compounds the composition of the species recognized may be explained. These species are: Meionite, Wernerite or Common Scapolite, Mizzonite (and Dipyre), Marialite. The limits of each are explained in the following pages; it is to be noticed, however, that no sharp line can be drawn between them, and a single locality in some cases has afforded specimens having widely different composition.

Lacroix, who has given an exhaustive memoir on the scapolite rocks of many different localities (Bull. Soc. Min., **12**, 83–360, 1889), shows that optically the series is characterized by the decrease in the strength of the double refraction in passing from meionite to marialite. In the table below, quoted from him (p. 357), group I includes the compounds from Me to $Me_2Ma_1$; II from $Me_2Ma_1$ to $Me_1Ma_3$; III from $Me_1Ma_3$ to Ma.

| I. | $\omega_y$ | $\epsilon_y$ | $\omega-\epsilon$ |

| II. | $\omega_y$ | $\epsilon_y$ | $\omega-\epsilon$ |
|---|---|---|---|
| Ersby | 1·570 | 1·547 | 0·023 |
| Arendal, Dx. | 1·566 | 1·545 | 0·021 |
| Pargas | 1·567 | 1·550 | 0·017 |
| III. | | | |
| Pyrenees, Dx., *Dipyre* | 1·558 | 1·543 | 0·015 |
| Pierrepont | 1·562 | 1·546 | 0·016 |

The Scapolites occur (1) in volcanic rocks, as in ejected masses on Mte. Somma (meionite); (2) in crystalline limestone, often as the direct result of contact metamorphism; (3) crystalline schists, augite-gneiss, etc.; (4) as an alteration product of a plagioclase feldspar sometimes on an extensive scale as with amphibole in the "gefleckter Gabbro" (Brögger and Reusch, Zs. G. Ges., **27**, 646, 1875) in connection with the apatite deposits of Ödegaarden near Bamle, Norway. Cf. Lcx., l.c., who has developed this subject at length; also Michel-Lévy, Bull Soc. Min., **1**, 43, 79, 1878; Judd, Min. Mag., 8, 186, 1889.

Meionite was the first species of the Scapolite group distinctly recognized. It is, however, probable that scapolite was included with lamellar pyroxene under the name of *White Schörl-Spar* (Skörlspat) by Cronstedt, who mentions Pargas, in Finland, as one of its localities. The names *Wernerite* and *Scapolite* were both introduced by d'Andrada (of Portugal) in the same article (Scherer's J., **4**, 35, 38, 1800), and applied to specimens from the same region in Norway. Wernerite is the *first* of the two in the article. Haüy used the names *Wernerite* and *Scapolite* (supposing the species distinct) in his Traité of 1801, but in his Mineralogical Course for 1804 or 1805 arbitrarily set aside the latter for *Paranthine.* Monteiro, a friend of d'Andrada's, and speaking in his behalf, protested in 1809 (J. Phys., **68**, 177) against the change, and after arguing that wernerite and scapolite were identical, both on chemical and crystallographic grounds, urged the adoption of the name *Wernerite* for the species. In the following pages the name Scapolite is retained for the group, so that the minerals may all be called *scapolites*, as those of the feldspar group are called feldspars; and the name Wernerite is applied to the most prominent division of the old species, including the common scapolite from many localities. In the fifth edition the compounds intermediate between meionite and wernerite were called paranthite, and those between wernerite and mizzonite were called ekebergite.

**Ref.**—[1] Ber. Ak. Wien, **88** (1), 1142, 1883, Min. Mitth., **7**, 400, 1886. Rammelsberg has also discussed the same subject recently, see Ber. Ak. Berlin, 589, 1885. Early papers on the composition of the species are those by Wolff, Inaug. Diss., Berlin, 1843; Rath, Pogg., **90**, 82, 288, 1863.

---

**386. MEIONITE.** Hyacinte blanche de la Somma *de Lisle,* Crist., **2**, 289, 290, Pl. IV, f. 118, 1783. Meionite *H.*, Tr., **2**, 1801. Mionite *Century Dictionary,* 1890.

[a] Often simply = loss on ignition.

Sipöcz found in Vesuvian meionite 0·74 p. c. Cl, 0·22 $SO_3$, Tsch., l. c.

Paranthite (paranthine), the name given in the 5th Ed. to the compounds between the Vesuvian meionite and wernerite (*e.g.*, anals. 4–7) is Haüy's name (as already noted) derived from *παρανθεῖν*, *to wither*, because it readily loses its luster.

**Pyr., etc.**—B.B. fuses with intumescence at 3 to a white blebby glass. Decomposed by acid without gelatinizing (Rath). Gmelin states it to be fusible with difficulty on the edges, and both Gmelin and Kobell state that it gelatinizes with hydrochloric acid. An examination of a specimen received from Scacchi fully confirms Rath's conclusions.

**Obs.**—Occurs in small crystals in cavities, usually in limestone blocks, on Monte Somma; the cavities are often lined with green mica. Also in ejected masses with sanidine, magnetite, titanite, augite, apatite at the Laacher See.

*Ersbyite* is from Ersby near Pargas, Finland. A variety of scapolite from Bolton, Mass., *Nuttalite* (see p. 469) is near ersbyite in composition.

Named by Haüy from *μεῖον*, *less*, the pyramid being less acute than that of vesuvianite.

**Ref.**—[1] Min. Russl., **2**, 105; Pogg., Erg., **3**, 478, 1851. Cf. also Rg., **94**, 434, 1855; Dx., Min., **1**, 221, 1862; Rath, ib., **119**, 262, 1863; Brezina, Min. Mitth., 16, 1872.

**Artif.**—Attempts to form meionite by fusion have resulted in obtaining an orthosilicate corresponding in composition to $Na_2O.5CaO.4Al_2O_3.9SiO_2$, but characterized by positive optical character. With a mixture of $6CaO.4Al_2O_3.9SiO_2$, anorthite was formed. By fusing a labradorite glass with white marble, anorthite and a tetragonal mineral with negative character was obtained. Bourgeois, Bull. Soc. Min., **5**, 15, 1882, Reprod. Min., 132, 1884.

Doelter states that his synthetic experiments (unpubl.) prove the existence of a tetragonal mineral, corresponding to meionite, having the composition $CaAl_2(SiO_4)_2$. Allg. Chem. Min., p. 258, 1890.

### 387. WERNERITE.

**387. WERNERITE.** Wernerite (fr. Norway) *d'Andrada*, J. Phys., **51**, 244, 1800, Scherer's J., **4**, 35, 1800. Scapolite (fr. Norway) *d'Andrada*, ib., 246, and ib., 38, 1800. | *ee″* | = 47° 21′ |  |  |  |  |  |  |

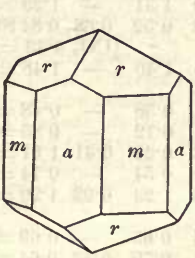
Crystals usually coarse, with rough uneven faces and often very large. The pyramidal hemihedrism sometimes shown (f. 3) in the development of the planes *z* (311) and $z_,$ (131). Also massive, granular, or with a faint fibrous appearance; sometimes columnar.

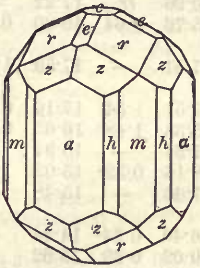
Cleavage: *a* and *m* rather distinct, but interrupted. Fracture subconchoidal. Brittle. H. = 5–6. G. = 2·66–2·73. Luster vitreous to pearly externally, inclining to resinous; cleavage and cross-fracture surface vitreous. Color white, gray, bluish, greenish, and reddish, usually light; streak uncolored. Transparent to faintly subtranslucent. Optically –. Double refraction weak. Indices:

Arendal $\omega_r = 1·566$ $\epsilon_r = 1·545$. See also p. 466.

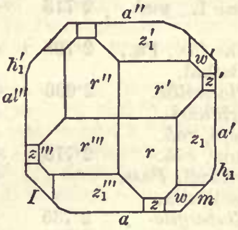
1.



2.



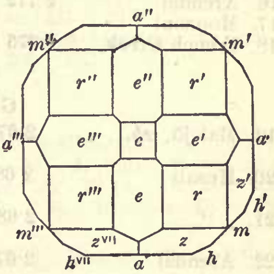
3.



Figs. 1, Common form. 2, 4, Grasse Lake, N. Y., Hovey. 3, Hirwensalo, Finland, Nd.

**Var.**—1. *Ordinary*. In crystals, white to gray, grayish green, brownish, and rarely, from impurity, nearly black. The prisms are sometimes several inches thick.

4.



*Nuttallite* (named after T. Nuttall) is white to smoky brown scapolite from Bolton, Mass. It has been shown to vary widely in composition; some kinds approach meionite, p. 467, and it is sometimes much altered. The crystals and massive variety of Chelmsford, Mass., of gray, greenish, and reddish shades of color, have been called *Chelmsfordite*.

*Passauite* or Porzellanspath is from Obernzell near Passau, Bavaria. Fuchs made the prisms probably about 92°, and so also did Schafhäutl. But Des Cloizeaux found that it was uniaxial and negative, and hence must be tetragonal in crystallization. Its colors are white to yellowish, bluish, and grayish white. The crystals are coarse, and irregularly grouped or single.

*Ontariolite* of *Shepard* is a glassy scapolite from Galway, Peterborough Co., Ontario; often black from inclusions, probably of graphite. It may prove, as suggested by Shepard, to belong with mizzonite and dipyre. G. = 2·608. Shepard's analysis gives $SiO_2$ 48·65 to 51·30, etc., but has little value because of the impurity of the material.

2. *Massive*. *Glaucolite* is of pale violet-blue, bluish, indigo-blue, to greenish gray colors, sometimes resembling cancrinite, but having the cleavage of scapolite. It is from near R. Sliudianka, near L. Baikal, Siberia, where it occurs in veins in granite The pink scapolite of Bolton is similar. Named from γλαυκός, *greenish gray* or *sea green*.

The so-called glaucolite of Weibye, from Norway, has been shown by Brögger to be sodalite (see p. 429), and a so-called glaucolite from L. Baikal also proved to be sodalite.

**Comp., Var.**—Intermediate between meionite and marialite and corresponding to a molecular combination of these in a ratio 3 : 1 to 1 : 2. The silica varies from 46 to 54 p. c., and as its amount increases the soda and chlorine also increase. Scapolites with silica from 54 p. c. to 60 p. c. are classed with mizzonite; they correspond to Me : Ma from 1 : 2 to 1 : 3 and upwards.

The percentage composition, for the simple compounds of Me : Ma, is as follows:

| Me : Ma | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | Cl | | |
|---|---|---|---|---|---|---|---|
| 3 : 1 | 46·10 | 30·48 | 19·10 | 3·54 | 1·01 | = | 100·23 |
| 2 : 1 | 48·03 | 29·16 | 17·04 | 4·76 | 1·35 | = | 100·34 |
| 1 : 1 | 51·90 | 26·47 | 12·90 | 7·15 | 2·04 | = | 100·45 |
| 1 : 2 | 55·85 | 23·73 | 8·67 | 9·62 | 2·75 | = | 100·62 |
| 1 : 3 | 57·85 | 22·35 | 6·53 | 10·87 | 3·10 | = | 100·70 |

The oxygen-equivalent of the chlorine is to be deducted.

[a] $Fe_2O_3$.
[b] Usually simply ignition and hence perhaps = $H_2O$ + Cl.

F. D. Adams, who first called attention to the common occurrence of chlorine in scapolites, shows that it is present in many varieties and in amounts varying up to 1·47, 2·01, 2·41 p. c. in scapolites from Ripon; also 2·01 p. c. in a specimen from Kragerö; 1·78 in one from Trumbull, Conn., etc., Am. J. Sc., **17**, 315, 1879.

**Pyr., etc.**—B.B. fuses easily with intumescence to a white blebby glass. Imperfectly decomposed by hydrochloric acid.

**Obs.**—Occurs in metamorphic rocks, and most abundantly in granular limestone near its junction with the associated granitic or allied rock; sometimes in beds of magnetite accompanying limestone. It is often associated with light-colored pyroxene, amphibole, garnet, and also with apatite, titanite, zircon; amphibole is a less common associate than pyroxene, but in some cases has resulted from the alteration of pyroxene. The scapolite of Pargas, Finland, is in limestone; that of Arendal in Norway, and Malsjö in Wermland, occurs with magnetite in limestone.

The *passauite* is from Obernzell, near Passau, in Bavaria.

In *Vermont*, at Marlborough, massive. In *Mass.*, at Bolton and Boxborough, in crystals, sometimes large; at Chelmsford; Littleton; Chester; Carlisle; Westfield, massive; at Parsonsfield and Raymond, near Dr. Swett's house, crystals, with yellow garnet. In *Conn.*, at Monroe, white and nearly fibrous; a stone quarry at Paugatuck, Stonington, massive. In *N. York*, at Two Ponds in Orange Co., reddish white crystals with pyroxene, titanite, zircon, one crystal 10 in. long and 5 in diameter; at Fall Hill, Monroe, of white and bluish colors, massive, with lamellar pyroxene; in Warwick of the same county, near Amity, milk-white crystals with pyroxene, titanite, graphite; 5 m. S. of Warwick, and 2 m. N. of Edenville, near Greenwood Furnace, are other good localities; in Essex Co., perfect crystals and massive nearly fibrous, white and greenish white, abundant near Kirby's graphite mine, 4 m. N. E. of Alexandria, in Ticonderoga, associated with pyroxene; at Crown Point; in Lewis Co., in fine crystals, white, bluish, and dark gray, presenting the play of light not unusual with this variety; edges of the crystals often rounded; Grasse Lake, Jefferson Co., in fine crystals; at Gouverneur, in limestone, also at Macomb, St. Lawrence Co. In *N. Jersey*, at Franklin and Newton, and 3 m. W. of Attleborough, crystallized, in limestone; also at Vernon, Franklin, and Sparta a scapolite rock with pyroxene, amphibole, orthoclase, also titanite. In *Penn.*, at the Elizabeth mine, French Creek, Chester Co., in cavities of a brownish gray garnet with magnetite, pyrite, and remains of the hessonite from which it was probably formed.

In *Canada*, at G. Calumet Id., massive lilac colored; at Hunterstown, in large crystals, with titanite; at Grenville, with pyroxene; Templeton; Bedford; Portland and Wakefield, Ottawa Co.; Algona, Renfrew Co. Scapolite rocks occur at several points, in part a "scapolite diorite" like that of Norway, chiefly in the Laurentian, as at Arnprior on the Ottawa R.; L. Mazinaw, Addington Co.; Robertsville mine, Frontenac Co.; McDougal, Parry Sound; it is associated with crystalline limestone, also amphibolytes and diorytes (Adams & Lawson, Can. Rec. Sc., **3**, 185, 1888).

**Alt.**—The scapolites as a class are especially liable to alteration, and the products are numerous and varied. The introduction of water, or of carbon dioxide, is a common change. By the substitution of potash, the mineral passes to the state of *pinite* and *potash mica*. By the acquisition of iron it passes in some cases to *epidote*. By the introduction of magnesia, it may pass to *steatite;* or of magnesia and potash, to a *magnesia mica*. By a loss of bases, the proportion of silica left increases; and by a loss of silica also (which may become opal in its separation), the mineral passes to a *kaolin*-like compound, a common result of its alteration. Moreover, silica may remain, and the altered crystal become by additions a siliceous pseudomorph, as occurs at Pargas. Various alteration-products are more particularly mentioned on p. 473.

**Ref.**—[1] Arendal, quoted by Tschermak. The angles as given by Koksharov are the same as for meionite; the variation is in any case small. [2] Cf. Mlr., Min., 382, 1852.

## 388. MIZZONITE. *A. Scacchi*, Pogg., Erg., **3**, 478, 1852.

DIPYRE. Schorl blanchâtre de Mauléon (Pyrenees) (discovered by Gillet-Laumont in 1786), Leucolite, *Delameth.*, Sciagr., **1**, 289, **2**, 401, 1792. Dipyre *H.*, Tr., **3**, 1801. Riponite *Tschermak*, Ber. Ak. Wien, **88** (1), 1142, 1883.

Tetragonal. Axis $\dot{c} = 0·44235$; $001 \wedge 101 = 23° 51\frac{3}{4}'$, Scacchi-Koksharov[1].

**Forms:** *c* (001, *O*), *a* (100, *i-i*), *m* (110, *I*), *h* (210, *i*-2), *e* (101, 1-*i*), *r* (111, 1).

Angles: *ee'* = 33° 15', *ee''* = 47° 43½', *rr'* = *44° 3', *cr* = 32° 2', *ar* = 67° 58½'.

In small prismatic crystals, with *m* prominent. Prismatic faces vertically striated. Sometimes acicular.

Cleavage *a*, *m*. H. = 5·5–6. G. = 2·623 Rath. Luster vitreous. Colorless to white. Transparent to translucent. Refractive indices (see also p. 466):

| | | |
|---|---|---|
| Pouzac, *Dipyre* | $\omega_r = 1·558$ | $\epsilon_r = 1·543$ Dx. |
| | $\omega_y = 1·5673$ | $\epsilon_y = 1·5416$ Lattermann. |

**Var.**—*Mizzonite* occurs in clear crystals in ejected masses on Mte Somma.

*Dipyre* occurs in elongated square prisms, often slender, sometimes large and coarse, in limestone and crystalline schists, chiefly from the Pyrenees. *Couseranite* is the same mineral and from the same region, but as originally analyzed in a more or less altered form, see anal. below.

*Prehnitoid*, named from its resemblance to prehnite, is from Sweden.

**Comp.**—Intermediate between meionite and marialite and corresponding to a molecular combination varying from Me : Ma = 1 : 2 to Me : Ma = 1 : 3. For percentage composition, see p. 469.

**Anal.**—1, Rath, Pogg., **119**, 254, 1863. 2, Adams, Am. J. Sc., **17**, 315, 1879. 3, Damour, L'Institut, 16, 1862. 4, Schulze, quoted by Gdt., Jb. Min., Beil., **1**, 226, 1881. 5, Delesse, C. [a] $Fe_2O_3$. [b] 0·72 hygroscopic. [c] MnO. [d] Ign.

**Pyr., etc.**—B.B. fuses easily, but with less intumescence than meionite. Only slightly acted upon by hydrochloric acid.

**Obs.**—*Mizzonite* occurs in trachytic bombs on Mte. Somma; the rock is gray and consists chiefly of sanidine and dark green augite; the mizzonite occurs in cavities, sometimes with calcite. Named from μείζων, *greater*, the axis of the prism being a little longer than in meionite.

*Dipyre* and *couseranite* are from various points, chiefly in the Hautes-Pyrénées, in granular limestone; at Pouzac, near Bagnères-de-Bigorre, with a white uniaxial mica; near Libarens, about a mile and a half from Mauléon, with mica or talc; at the baths of Aulus in the Dept. of Ariège; in a black schist on the right bank of the Lés, near Luzenac, Ariège; in the vicinity of Loutrin, near Angoumer, in blocks of granular limestone, with pyrite, titanite (see more particularly, Frossard, Bull. Soc. Min., **13**, 321, 1890); also at Biarritz and elsewhere in the Basses-Pyrénées. The *prehnitoid* is from a locality between Kongsberg and Solberg in Sweden. with coarsely crystallized hornblende; its hardness is stated by Blomstrand to be 7, and G. = 2 50. The scapolite associated with amphibole in the "geflecter Gabbro" or scapolite-dioryte of the apatite deposits near Bamle, Norway, is near dipyre in composition (see anal. 8 and p. 467) A scapolite belonging here occurs at the Llanca mine, district La Higuera, Coquimbo, Chili. According to Arzruni, dipyre (*rr'''* = 63° 49') occurs in saccharoidal limestone at Canaan, Ct.

*Riponite* (anal. 2) is from the township of Ripon, Ottawa Co.. Quebec, Canada.

The name *dipyre*, from δίς, *twice*, and πῦρ, *fire*, alludes to the two effects of heat, *fusion* and *phosphorescence*. *Prehnitoid* refers to a resemblance to *prehnite*.

**Alt.**—Dipyre undergoes very easy alteration, much easier than wernerite, and this it probably owes to the large percentage of soda. At all the localities the mineral occurs to a large extent in a crumbling state. Some of it appears to be changed to a greenish chlorite.

*Couseranite* is an altered form of dipyre. It occurs in the same region, and the dipyre may be seen passing into couseranite. Its square prisms are usually rough or rounded externally, and bluish black or grayish black to deep black in color, but sometimes whitish and blackish on the same specimen. It is often soft and fragile. Charpentier's mineral came from the department of Ariège (formerly Couserans). Analyses: 1, Dufrénoy, Ann. Mines, **4**, 327, 1828. 2, Pisani, Dx., Min., **1**, 234, 1862.

| | | $SiO_2$ | $Al_2O_3$ | FeO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 2·69 | $\frac{2}{2}$ 52·37 | 24·02 | — | 1·40 | 11·85 | 3·96 | 5·52 | — = 99·12 |
| 2. | | 58·33 | 20·20 | 1·90 | 7·20 | 0·99 | 0·76 | 8·82 | 2·35 = 100·55 |

Pisani's analysis was made on large square prisms from Pouzac. It has the composition of agalmatolite. Both of the analyses indicate the alteration by the amount of potash present.

**Ref.**—[1] On mizzonite, Somma, Scc. *rr'* = 44° 4', Kk. *rr'* = 44° 2', Min. Russl., **2**, 108, 1854; on dipyre from Pouzac, *rr'* = 44° 17', *er* = 22° 10', Dx., Bull. Soc. Min., **12**, 9, 1889.

**389. MARIALITE.** *Rath*, Zs. G. Ges., **18**, 635, 1866. [Not Marialite of Ryllo.]

Tetragonal. In crystals with *c* (001), *a* (100), *m* (110), *h* (210), *e* (101), *r* (111); angles near mizzonite, *rr'* = 44°.

H. = 5·5–6. G. = 2·566. Luster vitreous. Colorless, or white. Transparent to translucent.

**Comp.**—Approximating to the pure marialite of Tschermak, $Na_4Al_3Si_9O_{24}Cl$ = Silica 63·9, alumina 18·1, soda 14·7, chlorine 4·2 = 100·9, deduct (O = 2Cl) 0·9 = 100. The marialite of Rath corresponds closely to Me : Ma = 1 : 4.

**Anal.**—1, Rath, l. c., after deducting 4·5 p. c. magnetite: the specific gravity of the material analyzed was 2·626, or 2·566 correcting for admixed magnetite (G. = 5·18). 2, Rg., Min. Ch., Erg., 216, 1886.

| 2. | 61·40 | 19·63 | 4·10 | *undet.* | — | 4·00 | |

**Pyr., etc.**—Like those of mizzonite.

**Obs.**—From a volcanic rock called piperno, occurring at Pianura, near Naples.

**Altered Scapolites.** The following are the characters of different altered scapolites. Analyses are given below and on pp. 322, 323, 5th Ed.

Atheriastite *Weibye,* Pogg., **79**, 302, 1850. Like scapolite in form; color greenish; opaque. From Arendal, with black garnet and keilhauite. Contains 7 p. c. water.

Stroganovite *Herm.,* J. pr. Ch., **34**, 178, 1845. Has the form of scapolite (Kk., Min. Russl., **3**, 95). Color yellowish to light oil-green; luster greasy; translucent; H.=5·5, G.=2·79. B.B. fuses easily with intumescence. From the R. Sliudianka near L. Baikal in Eastern Siberia. The analysis afforded 6·4 p. c. $CO_2$, corresponding to 11·4 p. c. of $CaCO_3$.

Algerite *Hunt,* Am. J. Sc., **8**, 103, 1849. Occurs in slender square prisms, sometimes 2 or 3 in. long, embedded in calcite. Yellowish to gray and usually dull. Brittle. H. = 3–3·5; some crystals more altered, 2·5. G. = 2·697–2·712 Hunt; 2·78 Crossley. From Franklin, Sussex Co., N. J. The varying results of analyses, and the presence of calcium carbonate, of magnesia, and the relations to known examples of altered scapolite, confirm the view derived from the form and appearances, that algerite is an altered scapolite, and related to *pinite.*

Wilsonite *Hunt,* Logan's Rep. Can., 1853, 1863, Am. J. Sc., **19**, 428, 1855. A massive mineral from Bathurst, Canada, affording square prisms by cleavage, and having H. = 3·5, G. = 2·765–2·776; luster vitreous, a little pearly on cleavage surfaces; color reddish white, rose-red, and peach-blossom red. According to Chapman (Am. J. Sc., **20**, 269, 1855) its crystallization and other characters are essentially those of scapolite. It is associated with apatite, calcite, and pyroxene. Hunt in Rep. G. Can., 1863, makes it a variety of gieseckite. Occurs also in northern N. York.

**Anal.**—1, Weibye & Berlin, Poff. **79**, 302, 1850. 2, Hermann, J. pr. Ch., **34**, 177, 1845; anal. as given by Rg., Min. Ch., 718, 1860, after deducting $CaCO_3$ (6·40 $CO_2$). 3, Crossley, Dana Min., 680, 1850. 4. Hunt, Rep. G. Canada, p. 483, 1863.

| | $SiO_2$ | $Al_2O_3$ | FeO | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. *Atheriastite* | 38·00 | 24·10 | 5·60[a] | 22·64 | 2·80 | — | — | 6·95 | = 100·09 |
| 2 *Stroganovite* | 43·35 | 30·52 | 0·95[b] | 21·59 | — | 3·74 | — | — | = 100·15 |
| 3. *Algerite* | 49·96 | 24·41 | 1·48[b] | — | 5·18 | — | 9·97 | 5·06 | $CaCO_3$ [4·21 = 100·27 |
| 4. *Wilsonite* | $\frac{2}{2}$ 47·60 | 31·20 | — | 0·95 | 4·19 | 0·88 | 9·30 | 5·43 | = 99·55 |

[a] Incl. 0·78 MnO. [b] $Fe_2O_3$

Terenite *Emmons,* Rep. G. N. Y., 152, 1837. Has the form of scapolite, with H. = 2; G. = 2·53; luster a little pearly; color yellowish white or greenish; and is from a small vein in limestone at Antwerp, N. Y. It has not been analyzed, but is probably near algerite or wilsonite. The Pinitartiger Scapolit of *Schumacher* (Verz., 98, 1801), from Arendal, is probably similar to the algerite and other *pinite* pseudomorphs. It is described as occurring in crystals and massive, of a white, greenish, and other shades, and B.B. fusing easily. His *Talkartiger Scapolit,* from Arendal, appears to have been a *steatitic* pseudomorph, it being B.B. infusible.

*Mica from Arendal, Norway* (*Micarelle* of Abildgaard). The mica occurs embedded in quartz, and has, according to Rath, the form of 8-sided crystals of scapolite, 6 in. long. The crystals are covered with mica externally, and within consist throughout of an aggregation of the same mica. Cf. Wichmann, Zs. G. Ges., **26**, 701, 1874.

Gabbronite *Schumacher,* Verzeichn., 1801; Gabronite. Referred here by Sæmann, who observes that there are, in the École des Mines at Paris, crystals of it of the form of scapolite; Schumacher describes it as bluish gray, inclining to leek-green; also grayish mountain-green. luster feeble; fracture smooth like that of flint; G. = 2·947; having some resemblance to gabbro. The bluish gray variety from the Kenlig mine near Arendal, with black hornblende and calcite, and the other from Fredriksvärn, Norway, in syenite. Brögger refers the mineral to elæolite (p. 425).

Pseudo-Scapolite *N. Nordenskiöld,* Bidrag Finl. Min., 66, 1820. Wernerite altered to pyroxene. The crystals are large and contain crystals of pyroxene, which are most abundant toward the exterior; from Simonsby, near Pargas.

Paralogite *N. Nordensk.,* Bull. Soc. Moscow, **30**, 221, 1857. Has the form and angles of scapolite (Kk., Min. Russl., **3**, 187), and is probably altered wernerite. Colors white, bluish, reddish blue; G. = 2·665. The crystals, after action of acids, are full of worm-like holes, owing to the separation of the calcium carbonate present. From the lapis-lazuli locality in the L. Baikal region.

*Steatitic* pseudomorphs occur at Newton, N. J., and Arendal in Norway. A *siliceous* scapolite of Pargas, of a gray color, in limestone, contains 92·71 p. c. of silica. *Albite* is announced by Tschermak as occurring pseudomorphous after scapolite.

The passauite is the source, by its alteration, of a large bed of porcelain earth or kaolin. Part of the kaolin has the prismatic form of the passauite. Opal occurs in the kaolin as one result of the alteration

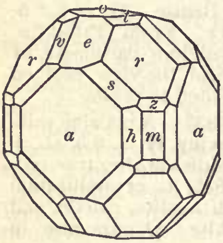
**390. SARCOLITE.** Sarcolite *Dr. Thompson* (of Naples), 1807. [Not Sarcolite du Vicentin (= Gmelinite) *Faujas, Vauq.*, Ann. Mus., **9**, 249, 1807, **11**, 42.] Analcime carnea *Mont. & Cov.*, Min. Vesuv., 1825.

Tetragonal; with pyramidal hemihedrism. Axis $\dot{c}$ = 0·88737; 001 ∧ 101 = 41° 35′ Brooke[1].

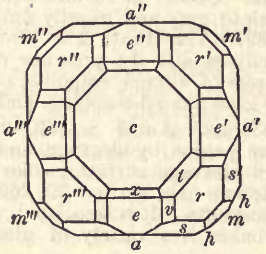
**Forms**[2]: *c* (001, *O*); *a* (100, *i-i*), *m* (110, *I*), *h* (210, *i*-2); *e* (101, 1-*i*); *t* (113, ⅓), *r* (111, 1), *z* (331, 3)[3]; *v* (313, 1-3), *s* (311, 3-3).

*ce* = 41° 35′ *cz* = 75° 7½′ *ee′* = 83° 10′ *ar* = 56° 26′
*ct* = 22° 42′ *cv* = 43° 5′ *rr′* = 67° 9′ *av* = 77° 31½′
*cr* = *51° 27′ *cs* = 70° 23′ *as* = 26° 40′ *ss′* = 49° 50′

1.



2.



1, 2, Mte. Somma. 1, Hbg.[3]; 2, Rath[4].

In small crystals, resembling the cubo-octahedron of the isometric system; often highly modified and sometimes hemihedral in the planes *v*, *s*.

Fracture conchoidal. Very brittle. H. = 6. G. = 2·545 Brooke; 2·932 Rg. Luster vitreous. Color flesh-red to rose-red, reddish white. Transparent to subtransparent. Optically +. Double refraction strong.

**Comp.**—An orthosilicate of aluminium, calcium, and sodium, $R_3Al_2Si_3O_{12}$ or $3RO.Al_2O_3.3SiO_2$, with R = Ca : $Na_2$ = 9 : 1, hence: Silica 39·9, alumina 22·6, lime 33·4, soda 4·1 = 100. The formula is analogous to that of the Garnet Group.

**Anal.**—Rg., Pogg., **109**, 570, 1860; earlier Scacchi, 5th Ed., p. 318.

$SiO_2$ $\frac{8}{3}$ 40·51 $Al_2O_3$ 21·54 CaO 32·36 $Na_2O$ 3·30 $K_2O$ 1·20 = 98·91

**Pyr., etc.**—B.B. fuses to a white enamel. With acids gelatinizes.

**Obs.**—Of rare occurrence in the ejected masses on Monte Somma, Vesuvius.

Named from σάρξ, *flesh*, and λίθος, *stone*, in allusion to the color.

**Ref.**—[1] Made cubic by Haüy, and early confounded with analcite, but shown to be tetragonal by Brooke, Phil. Mag., **10**, 189, 1831. Cf. also Mlr., Min., 381, 1852; Kk., who gives *ce* = 41° 30½′, Min. Russl., **2**, 109, 1854; Rg., *ce* = 41° 33′, l. c. [2] See Mlr., l. c. [3] Hbg., Min. Not., **1**, 14, 1856. [4] Ber. nied. Ges., p. 134, June 6, 1887.

---

## 8. Melilite Group. Tetragonal.

| | | | |
|---|---|---|---|
| 391. | Melilite | $Na_2(Ca,Mg)_{11}(Al,Fe)_4(SiO_4)_9$ | $\dot{c}$ = 0·4548 |
| | Åkermanite (artif.) | $Ca_4Si_3O_{10}$? | $\dot{c}$ = 0·45 approx. |
| 392. | Gehlenite | $Ca_3(AlO)_2(SiO_4)_2$ | $\dot{c}$ = 0·4001 |

---

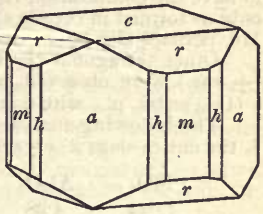
**391. MELILITE.** Mélilite *Delameth.*, T. T., **2**. 273, 1796; *Fl. Bellevue* (its discov. in 1790), J. Phys., **51**, 456, 1800. Humboldtilite *Mont. & Cov.*, Prodr., 375, 1822. Somervillite *Brooke*, Ed. J. Sc., **1**, 185, 1824. Zurlite *Ramondini*, Breislak Inst. Geol. **3**, 210, 1818. Mellilite.

Tetragonal. Axis $\dot{c}$ = 0·45483; 001 ∧ 101 = 24° 27½′ Des Cloizeaux[1].

**Forms**[1]: *c* (001, *O*); *a* (100, *i-i*), *m* (110, *I*), *h* (310, *i*-3); *r* (111, 1).

Angles: *ah* = 18° 26′, *rr′* = 44° 59′, *rr″* = *65° 30′, *ar* = 67° 30½′, *cr* = 32° 45′.

Cruciform twins rare, the vertical axes only slightly inclined or crossing nearly at right angles. Usually in short square prisms (*a*) or octagonal prisms (*a*, *m*), also in tetragonal tables.



Cleavage: *c* distinct; *a* indistinct. Fracture conchoidal to uneven. Brittle. H. = 5. G. = 2·9–3·10. Luster vitreous, inclining to resinous on a surface of fracture. Color white or pale yellow, honey-yellow, greenish yellow, reddish brown, brown. Translucent and in thin laminæ transparent; also opaque. Pleochroism distinct in yellow varieties. Sometimes exhibits optical anomalies. Optically −; also, in part, apparently isotropic or + (Vogt). Double refraction weak. Indices:

*Humboldtilite* $\omega_r = 1{\cdot}6312$ $\omega_y = 1{\cdot}6339$ $\epsilon_r = 1{\cdot}6262$ $\epsilon_y = 1{\cdot}6291$ Henniger[2].

**Comp.**—Perhaps $\overset{\text{II}}{R}_{12}\overset{\text{III}}{R}_4Si_9O_{36}$ or $Na_2(Ca,Mg)_{11}(Al,Fe)_4Si_9O_{36}$ for melilite (Rg.), but uncertain since the analyses fail to agree. If Ca : Mg = 8 : 3, and Al : Fe = 1 : 1, the percentage composition is: Silica 37·7, alumina 7·1, iron sesquioxide 11·2, lime 31·3, magnesia 8·4, soda 4·3 = 100. Potassium is also present. Groth writes the formula $(Ca,Mg)_6(Al,Fe)_2Si_5O_{19}$.

**Anal.**—1, Kbl., Schw. J., **64**, 293, 1832. 2–4, Damour, Ann. Ch. Phys., **10**, 59, 1844. 5, Schulze (on 0·38 gr.), Jb. Min., Beil., **2**, 383, 1883.

[a] FeO.

**Pyr., etc.**—B.B. fuses at 3 to a yellowish or greenish glass. With the fluxes reacts for iron. Decomposed by hydrochloric acid with gelatinization.

**Obs.**—*Humboldtilite* occurs in cavernous blocks on Monte Somma with greenish mica, also apatite, augite; the crystals are often rather large, and covered with a calcareous coating; less common in transparent lustrous crystals with nephelite, sarcolite, and sparingly, apatite, wollastonite, lining cavities in an augitic rock.

*Melilite* of yellow and brownish colors, is found at Capo di Bove, near Rome, in leucitophyre with nephelite, phillipsite, gismondite, magnetite, and small black crystals of augite and hornblende. *Somervillite*, which Des Cloizeaux has shown to have the angles of this species, is found at Vesuvius in dull yellow crystals.

Melilite[3] is not uncommon in certain basic eruptive rocks, as the *melilite-basalts* of Hochbohl near Owen in Württemberg, of the Schwabian Alb, of Görlitz, the Erzgebirge; also in the nephelite basalts of the Hegau, of Oahu, Sandwich Islands, etc.; perovskite is a common associate. It usually appears in square, octagonal or rounded tables, which are lath-shaped for sections ⊥ *c*, and they show either fine striations or peculiar peg-shaped or spear-shaped inclusions to which the name "Pflockstructur" was given by Stelzner.

*Zurlite* occurs in opaque square or octagonal prisms in calcareous blocks on Monte Somma with humboldtilite; color whitish or asparagus-green; H. about 6; G. = 3·27; B.B. infusible; soluble in nitric acid. It is impure humboldtilite (Scacchi, Jb. Min., 261, 1853). Named after Sign. Zurlo. Melilite is named from μέλι, *honey*, in allusion to the color.

**Artif.**—Common in furnace slags, having been observed in square prisms at Russel's Hall, Tipton, Dowles, Wicks, etc., in England and Wales, near St. Etienne in France, near Charlevoi in Belgium, Königshütte in Upper Silesia, Mägdesprung in the Harz, and Easton, Pa. Cf. Percy, Rep. Brit. Assoc., 351, 1846; also Vogt, Ak. H. Stockh., Bihang, **9** (1), 105, 1884–85.

Obtained from fusion by Fouqué and Lévy in square prisms, Bull. Soc. Min., **2**, 108, 1879. Also by Bourgeois, who has obtained a series of compounds ($2RO.\frac{1}{2}R_2O_3.3SiO_2$) in part colorless, also ferriferous and again manganesian, the last of a violet tint with distinct dichroism, Ann. Ch. Phys., **29**, 450, 1883, and Reprod. Min., 122, 1884. Vogt has described a series of melilites from slags varying in optical character from the usual negative, through forms sensibly isotropic, to others which are positive, like åkermanite, p. 476.

**Ref.**—[1] Dx., Min., p. 215, 1862, he makes *r* = 221. [2] Rosenbusch, Mikr. Phys., 323, 1885. [3] Cf. Zirkel, Basaltgesteine, 77, 1870; also Stelzner, Jb. Min., Beil., **2**, 369, 1883.

**Åkermanite** *I. H. L. Vogt*, Ak. H. Stockh., Bihang, **9** (1), 126, 1884–85; Arch. Math. Nat., **13**, 310, 1890. A tetragonal species isomorphous with melilite and gehlenite. Inferred to have the composition $R_4Si_3O_{10}$ or $4RO.3SiO_2$ ; R = Ca chiefly, with also Mg,Mn,Fe. Known only as formed in certain slags on rapid cooling. Obtained in thin tabular crystals. Cleavage: 110, perhaps also 001. Optically uniaxial and +.

Other tetragonal crystals, also optically +, intermediate between åkermanite and melilite (+ var.) were observed, in part twins crossing at an angle of 48½°, and hence corresponding to *e* (101) as tw. pl., with $\dot{c}$ = 0·45. Named for the Swedish metallurgist, Richard Åkerman.

The following analyses by Damm (quoted by Vogt) belong to a compound near åkermanite, 1, the entire slag; 2, crystals separated from the slag.

| $SiO_2$ | $Al_2O_3$ | FeO | MnO | CaO | MgO | |
|---|---|---|---|---|---|---|
| 42·44 | 4·38 | 0·30 | 9·21 | 28·37 | 11·87 | $CaS_2$ 1·89 = 98·46 |
| 43·17 | 3·43 | *tr.* | 5·85 | 37·89 | 9·0[a] | = 99·34 |

[a] Approx.

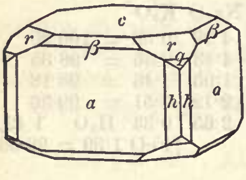
**392. GEHLENITE.** Gehlenit *Fuchs*, Schw. J., **15**, 377, 1815. Stylobat *Breith.*, Leonh. Taschenb., **10**, 600, 1816, Hoffm. Min., **4** b, 109, 1817.

Tetragonal. Axis $\dot{c}$ = 0·40006; 001 ∧ 101 = 21° 48¼′ Des Cloizeaux[1].

**Forms:** *c* (001, *O*); *a* (100, *i i*), *h* (310, *i*-3); *β* (703, $\frac{7}{3}$-*i*)?; *r* (111, 1), *s* (887, $\frac{8}{7}$), *q* (221, 2).

**Angles:** *cβ* = 43° 2′ *cr* = *29° 30′, *cs* = 32° 53′, *cq* = 48° 32′, *rr′* = 40° 45′, *ss′* = 45° 9′, *qq′* = 63° 59½′.

Crystals usually short square prisms; sometimes tabular; often resembling cubo-octahedrons.



Monzoni, Dx.

Cleavage: *c* imperfect; *a* in traces. Fracture uneven to splintery. Brittle. H. = 5·5–6. G. = 2·9–3·07. Luster resinous, inclining to vitreous. Color different shades of grayish green to liver-brown; none bright. Faintly subtranslucent to opaque. Streak white to grayish white. Optically negative. Double refraction weak.

**Comp.**—$Ca_3Al_2Si_2O_{10}$ or $3CaO.Al_2O_3.2SiO_2$ = Silica 30·9, alumina 26·2, lime 42·9 = 100.

Some ferric iron, replacing the aluminium, is present and some magnesium replacing the calcium.

The formula may be written (Groth) as a basic orthosilicate, $Ca_3(AlO)_2(SiO_4)_2$.

**Anal.**—1, Rg., Min. Ch., 732, 1860. 2, Dmr., Ann. Ch. Phys., **10**, 66, 1844. 3, Lemberg, Zs. G. Ges., **24**. 248, 1872. 4, 5, Kuhn, Lieb. Ann., **59**, 371, 1846. 6, 7, Janovsky, Ber. Ak. Wien, **69** (1), 28, 1874. The material of anal. 6 contained some vesuvianite.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CaO | MgO | ign. | |
|---|---|---|---|---|---|---|---|---|---|
| 1. Monzoni | | 29·78 | 22·02 | 3·22 | 1·63 | 37·90 | 3·88 | [1·38] | MnO 0·19 = 100 |
| 2. " | | 31·60 | 19·80 | 5·97 | — | 38·11 | 2·20 | 1·53 | $Na_2O$ 0·33 = 99·54 |
| 3. " | | 30·01 | 21·33 | 3·56 | — | 36·74 | 3·77 | 4·72 | = 100·13 |

**Pyr., etc.**—B.B. thin splinters fuse with difficulty (F. = 5·7, Kbl.) to a gray glass. With borax fuses slowly to a glass colored by iron. Gelatinizes with hydrochloric acid, yielding a solution containing both protoxide and sesquioxide of iron.

**Obs.**—Gehlenite is found at Mount Monzoni, in the Fassathal, in isolated or aggregated crystals, invested by calcite, formed as a contact mineral in limestone; also in the Fleimsthal; in rolled pebbles at Orawitza in the Banat inclosing grains of vesuvianite, Zeph., Ber. Ak. Wien, **69** (1), 26, 1874.

Named by Fuchs after his colleague, Gehlen.

**Alt.**—Gehlenite occurs altered to steatite, also to fassaite, and to grossular garnet (see below). A pseudomorph from Monzoni gave Lemberg (l. c.):

$SiO_2$ 28·75 $Al_2O_3$ 17·83 $Fe_2O_3$ 3·41 MgO 29·60 CaO 4·76 ign 15·93 = 100·28

An alteration product, inclosing the Orawitza gehlenite, of a red to brown color, H. = 3·5 amorphous, gave Janovsky:

G. = 1·87 Vrba $SiO_2$ 29·12 $Al_2O_3$ 31·46 $Fe_2O_3$ 8·86 $H_2O$ 30·56 = 100

Pseudomorphs after gehlenite from Monzoni have been described by Cathrein, consisting (1) of fassaite, and (2) of grossularite, Min. Mitth., **8**, 408, 412, 1887. Anal.—Cathrein:

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CaO | MgO | ign. | |
|---|---|---|---|---|---|---|---|---|
| 1. *Fassaite* | 44·22 | 12·37 | 3·83 | 1·14 | 27·31 | 11·26 | 0·73 | = 100·86 |
| 2. *Grossularite* | 39·64 | 16·47 | 4·62 | 1·13 | 31·52 | 5·72 | 1·04 | = 100·14 |

**Artif.**—Not unfrequent among furnace scoria, in thin square tables, or 8-sided prisms, with cleavage parallel to the lateral planes of a square prism. Has been observed at Dawes' furnace, Oldbury in England, and at Holzhausen in Hesse. Also similarly at McVille, Armstrong, Penn. Diller, Am. J. Sc., **37**, 220, 1889. See also Vogt, ref. under åkermanite, p. 476.

Obtained by Bourgeois from fusion, in minute square prisms optically uniaxial and negative, compounds of various composition were obtained, but especially the pure $Ca_3Al_2Si_2O_{10}$, Ann. Ch. Phys., **29**, 448, 1883; Reprod. Min., 122, 1884.

**Ref.**—[1] Min., **1**, p. 214, 1862.

CACOCLASITE *H. C. Lewis*, Proc. Acad. Philad., Nov. 26, 1883, Amer. Nat., **18**, 416, 1884. A pseudomorphous mineral occurring with spinel, pyroxene, graphite, pyrrhotite, embedded in a blue calcite at Wakefield, Ottawa Co., Quebec. In square prisms or resembling cubo-octahedrons, with forms: *c* (001), *a* (100), *m* (110), *l* (201), *q* (221), *u* (211), *s* (621); apparently hemihedral in the zirconoid planes, but forms and angles somewhat uncertain. Approximate angle $cq = 50\frac{1}{2}°$, which gives $\dot{c} = 0·429$. No cleavage. H. = 5–6. G. = 3·053. Luster vitreous to resinous; surface of crystals shining and glazed as if vitrified. Color white or grayish white. Under the microscope is resolved into an amorphous ground-mass, a colorless mineral (tetragonal?), and grains of calcite.

Anal.—1, R. Haines (deducting calcite), quoted by Lewis. 2, 3, Genth, Am. J. Sc., **38**, 200, 1889.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | $P_2O_5$ | $CO_2$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 3·057 | 36·74 | 19·79 | 1·33 | 38·16 | 0·77 | 0·32 | 0·17 | 0·23 | 2·49 | — | = 100 |
| 2. | 3·337 | 31·52 | 17·34 | 0·51 | 40·95 | *tr.* | *tr.* | *tr.* | 1·04 | 2·19 | 6·73 | = 100·28 |
| 3. | 3·222 | 32 67 | 19·63 | 0·39 | 36·38 | 0·49 | 0·31 | 0·20 | 2·28 | 3·36 | 4·25 | = 99·96 |

Genth concludes that the material of anal. 2 contains: quartz 23·04 p. c., apatite 5·05, calcite 15·20; of anal. 3, quartz 11·63, apatite 7·74, calcite 9·66.

B.B. fuses with intumescence at 3. Hardly soluble in acids, but gelatinizes after fusion. Named from κακός, *bad*, κλάσις, *fracture*, in allusion to the want of cleavage, which, however, in a pseudomorph is not significant. The similarity to gehlenite in occurrence is worth noting, and the apparent relation to sarcolite in forms and in angle is also to be noted.

## 9. Vesuvianite Group. Tetragonal.

**393. Vesuvianite** $H_4Ca_{12}(Al,Fe)_6Si_{10}O_{43}$? $\dot{c} = 0·5372$

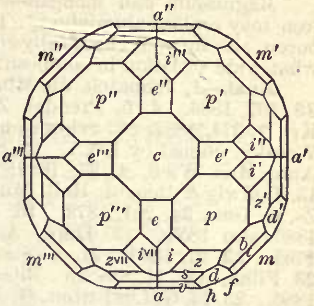
Crystals commonly prismatic, often terminated by *c*, or by *c* and *p* alone; sometimes the prism wanting and the form a low pyramid; again sharp pyramidal, *t* (331), or terminated by the zirconoid *s* (311). Also massive; columnar, straight and divergent, or irregular; granular massive; cryptocrystalline.

Cleavage: *m* not very distinct; *a* and *c* still less so. Sometimes a lamellar structure ∥ *c*, and a tendency to scale off in thin layers often observed on all the faces of a crystal. Fracture subconchoidal to uneven. Brittle. H. = 6·5. G. = 3·35–3·45. Luster vitreous; often inclining to resinous. Color brown to green, and the latter frequently bright and clear; occasionally sulphur yellow, and also pale blue. Streak white. Subtransparent to faintly subtranslucent. Dichroism not usually strong: for $\omega$, colorless or yellowish; for $\epsilon$, reddish, yellowish, or greenish.

12.



12, Vesuvius, after Haidinger.

Optically −; also + rarely, as for viluite, Prendel. Double refraction very weak. Sometimes abnormally biaxial[8]. Color, optical character and refractive power often variable in successive concentric layers of the same crystal. Indices:

Ala, *green cryst.*, $\omega_y = 1{\cdot}719$–$1{\cdot}722$ $\epsilon_y = 1{\cdot}718$–$1{\cdot}720$ Dx.[9]
" $\omega_y = 1{\cdot}7235$ $\epsilon_y = 1{\cdot}7226$ Osann[9]

A division of a basal section into four diagonal biaxial sectors is very common.

An Ala vesuvianite gave Brezina: $2E_r = 62° 25'$. $2E_y = 62° 47'$. Klocke found the central portion of a section uniaxial, while the whole was divided into four biaxial sectors, the ax. plane normal to the edge, and the angle increasing toward the edge, the maximum axial angles being $2E_r = 28° 43'$ Li, $2E_y = 30° 32'$ Na, $2E_{gr} = 32° 30'$ Tl. Pressure served to diminish the axial angle in the sectors to which its direction was parallel, but increased it in the others. Variation of the axial angle with change of temperature has been shown by Doelter.

Sections of viluite ∥ *m* (Prendel) had normal extinction ∥ and ⊥ *c*. but consisted of two parts, A and B, each shaped like an hour-glass (A with axis ∥ and B ⊥ *c*). Sections ∥ *c* showed within the substance A, with feeble double refraction, nearly uniaxial; without, B, in parallel zones, with strong double refraction and an axial angle of 30° to 35°, the ax. plane parallel on each side to the outline of the crystal (*m* and *a*). Both parts were optically +. Upon heating to 200°–300°, the middle portion became uniaxial, and the axial angle of the exterior zones diminished to 10° when near a red heat; the change was permanent after long heating and sudden cooling. Further the parts A were found to be pyroelectrically + (on cooling), the parts B were −.

For the part A, G. = 3·290–3·295; for B, G. = 3·320–3·324. The highest value of G. obtained was 3·331. Separate analyses of the parts A and B of the crystals whose entire composition is given beyond (anal. 4, 5), gave nearly identical results, a slight apparent difference only in the amounts of $Fe_2O_3$ and FeO being shown.

**Var.**—1. *Ordinary.* Common color green, of various shades, to brown. Crystals usually short stout square prisms, also pyramidal. Sometimes massive, compact, and somewhat resembing jadeite, for which it has been mistaken (see below).

The mineral from Gökum in Finland has been called *Gahnite, Loboite, Gökumite*, and that from Frugård, *Frugårdite.* The last is in brown and green crystals, with G. = 3·349, Nd. *Jevreinovite*, which also is from Frugård, in the parish of Mäntzälä, is but little magnesian or not at all so; it occurs in pale brown to colorless crystals; G. = 3·39. *Heteromerite* occurs in small oil-green prisms in the district of Zlatoust, Ural. Egeran is a subcolumnar brown variety, from Eger in Bohemia.

So-called *colophonite* from Arendal has proved to be vesuvianite, though it had been previously referred to garnet.

*Xanthite* is a yellowish brown vesuvianite, from near Amity, N. Y., the crystals not differing from those of the common variety; it contains 2·80 p. c. MnO. A manganesian variety, from St. Marcel, Piedmont, has a sulphur to honey-yellow color. The *mangan-vesuvianite* (mangan-idocrase) from Jordansmühl contains 3·2 p. c. MnO (anal. 9), and that from Pajsberg contains 12·5 p. c. MnO (anal. 23).

2. *Cyprine.* Pale sky-blue or greenish blue; owing its color to a trace of copper, whence the name; from Tellemarken, Norway (anal. 26).

**Comp.**—A basic calcium-aluminium silicate, but of uncertain formula. The analysis of Ludwig-Renard gives $H_4Ca_{12}(Al,Fe)_6Si_{10}O_{43}$ or $H(OH)_3Ca_{12}(Al,Fe)_6(SiO_4)_{10}$.

Rammelsberg, who shows that the ratio of $\overset{\text{II}}{R} : \overset{\text{III}}{R} = 2 : 1$, while $\overset{\text{I}}{R} : \overset{\text{II}}{R}$ varies widely, regards the general formula as $4\overset{\text{I}}{R}_4SiO_4.\overset{\text{I}}{R}_6SiO_5 = \overset{\text{I}}{R}_{22}Si_5O_{21}$, which is more specially written $n\,\overset{\text{I}}{R}_{22}Si_5O_{21} + m\,(4\overset{\text{II}}{R}_{11}Si_5O_{21}.\overset{\text{III}}{R}_{22}Si_{15}O_{53})$.

Magnesium and manganese are often present and alkalies in small quantities, while ferric iron may replace aluminium. Titanium is also often present in small amount, and fluorine and boron, also further, chemically combined water. Specimens from different localities show a somewhat wide variation in composition not to be explained by simple replacement.

**Anal.**—1, Jannasch, Jb. Min., **2**, 132. 1883. 2, Id., ibid., **1**, 269, 1884 3, Rg., Zs. G. Ges., **38**, 507, 1886. 4, 5, Prendel, Zs. Ges., **24**, 201, 1872. 16, Ludwig & Renard, l. c. 17, Rg., l. c., 1873. 18, Id., l. c., 1886 (also 1855). 19, Dmr., Ann. Ch. Phys., **23**, 157, 1871. 20, G. Nordenskiöld, G. För. Förh., **12**, 27, 1890. 21, A. Stenberg, ibid., p. 28. 22, Cossa, Att. Acc. Torino, **13**, 539, 1884. 23, Flink, Ak. H. Stockh., Bihang, **12** (2), 2, p. 56, 1887. 24, Igelström, Bull. Soc. Min., **9**, 22, 1886. 25, 26, G. Lindström, G. För. Förh., **10**, 286, 1888. 27, J. Lawrence Smith, Am. J. Sc., **8**, 435, 1874. 28–37, J. H. Vogel, Inaug. Diss., Göttingen, 1888.

**Pyr., etc.**—B.B. fuses at 3 with intumescence to a greenish or brownish glass. Magnus states that the density after fusion is 2·93–2·945. With the fluxes gives reactions for iron, and some varieties a strong manganese reaction. Cyprine gives a reaction for copper with salt of phosphorus. Partially decomposed by hydrochloric acid, and completely when the mineral has been previously ignited.

**Obs.**—Vesuvianite was first found among the ancient ejections of Vesuvius and the dolomitic blocks of Monte Somma. It has since been met with most abundantly in granular limestone; also in serpentine, chlorite schist, gneiss, and related rocks; often as a contact formation. It is often associated with grossular garnet and diopside, wollastonite, also epidote, titanite.

At Vesuvius it is hair-brown to olive-green, and occurs sometimes in highly modified crystals with garnet, mica, nephelite, glassy feldspar, etc.; in the Albani Mts.; on the Mussa Alp in the Ala valley, in Piedmont, it is in transparent green or brown brilliant crystals, in chlorite schist and serpentine with diopside, ripidolite, etc. Found also at Mt. Monzoni in the Fassathal; Cziklowa in Hungary; at Orawitza and Dognaczka; Haslau near Eger in Bohemia (*egeran*); near Jordansmühl, Silesia at Gleinitz, also at Johnsberg; Zermatt with almandite; in the Pfitschthal and the Zillerthal in Tyrol; at the Achmatovsk mine, Zlatoust, Ural; on the Vilui river, near L. Baikal (sometimes called *wiluite* or viluite, like the grossular garnet from the same region); at Pajsberg, Sweden; at Gökum a variety containing manganese, also at Jakobsberg; at Arendal, "*colophonite;*" at Egg, near Christiansand; from the Hamrefjeld in the Eker parish, between Kongsberg and Drammen; in Finland at Frugård, Lupikko, etc.

A massive form, mixed with diopside, occurs on the south side of the Piz Longhin, in the Bergellthal, and in rolled masses in the bed of the stream Ordlegna near Casaccia in the Upper Engadine. At first taken for "jadeite" (Fellenberg, Jb. Min., **1**, 103, 1889), but referred to vesuvianite by Damour and positively identified by the analyses of Berwerth (anal. 12), Rammelsberg and Frenzel.

In N. America, in *Maine* at Phippsburg and Rumford, just below the falls, in crystals and massive with yellow garnet, pyroxene, etc., in limestone; at Parsonsfield, with the same minerals, abundant; at Poland and Sandford (fig. 11). In *N. Hampshire*, at Warren with cinnamon-stone. In *Mass.*, near Worcester, in a quartz rock, with garnet, but exhausted. In *N. York*, ½ m. S. of Amity, grayish and yellowish brown crystals, sometimes an inch in diameter, in granular limestone; also at the village, and a mile east of the village, of yellow, greenish yellow, and yellowish brown colors. In *New Jersey*, yellowish brown in crystals at Newton, with corundum and spinel. In *California* near San Carlos in Inyo Co., with grossularite and datolite.

In *Canada*, at Calumet Falls, Litchfield, Pontiac Co., in large brownish yellow crystals in limestone with brown tourmaline; at Grenville in calcite, in wax-yellow crystals with garnet, pyroxene, zircon; at Templeton, Ottawa Co., Quebec, in brownish red crystals in a quartzose rock, and at Wakefield, green and bright yellow, with grossular garnet.

Named *Vesuvian* by Werner, from the first known locality. Werner supposed the mineral to be exclusively volcanic; but as this idea is not expressed, the name is no more objectionable than all others derived from the names of localities. The earlier name, *Hyacinthine,* is bad, as the mineral is not the hyacinth of either ancient or modern time. Haüy's later name, *Idocrase* (subjective, like many others of his) is from εἶδος, and κρασις, *mixture* in allusion to a resemblance between the crystalline forms and those of other species. Nothing in its signification, or in anything else, makes it right to substitute this for Werner's name In English, the word *vesuvian* has the objection of being an adjective in form and use; but this is avoided by giving it the mineralogical termination above employed.

*Loboite* was named for Lobo da Silveira; *gahnite* for the Swedish chemist Gahn; *xanthite* from ξανθός, *yellow;* heteromerite from ἕτερος and μέρος in allusion to a supposed variation from the normal composition.

[a] $Li_2O$.

[b] $Mn_2O_3$.

**Alt.**—Alteration nearly as in garnet, with a far greater tendency to become hydrated. Crystals from Maine often have the exterior, though still brilliant and glassy, separating easily from the part below, and equally so, parallel to all the smaller as well as larger faces, so that a pealed crystal has as brilliant and even planes as before. Pseudomorphs include steatite, mica, clinochlore, diopside, and garnet.

**Artif.**—Not certainly obtained by artificial methods as yet, though claimed by Mitscherlich and later Daubrée. From the fusion of vesuvianite, Doelter and Hussak have obtained a mixture containing meionite, melilite, anorthite, and a calcium-chrysolite; see Doelter and Hussak, Jb. Min., **1**, 173, 1884, also Doelter, Min. Mitth., **10**, 86, 1888.

**Ref.**—[1] Piedmont, Preisschrift, 96, 1825, confirmed by Kk. Mohs-Haid. give *pp'* = 50° 31'; Zeph. shows that crystals from different localities vary somewhat widely, cf. also Kk., Min. Russl., **1**, 92, 1853. **9**, 156, 1884; Svr. Zs. Kr., **1**, 251, 1877; Mem. Acc. Linc., **4**, 101, 1887, **5**, 305, 1888; or Jb. Min., **2**, 35, 1888: ibid., **1**, 1, 1891. The variation of angle as bearing upon the crystalline system has been particularly studied by Doelter, Zs. Kr., **5**, 289, 1881.

## 10. Zircon Group. $\overset{IV}{R}SiO_4$. Tetragonal.

| | | |
|---|---|---|
| **394. Zircon** | $ZrSiO_4$ | $\dot{c}$ = 0·6404 |
| **395. Thorite** | $ThSiO_4$ | $\dot{c}$ = 0·6402 |

By some authors, Zircon and Thorite are treated as oxides and included in the RUTILE GROUP (p. 233), to which they approximate closely in form. For example, Groth doubles the formula of Rutile and writes it $TiTiO_4$, which may then be regarded as corresponding to the $ZrSiO_4$ of Zircon. A similar form belongs also to the tantalate, Tapiolite, and to the phosphate, Xenotime; further, compound groups consisting of crystals of Xenotime and Zircon in parallel position are not uncommon.

**394. ZIRCON.** *Λυγκύριον* (= Lyncurium)? *Theophr.* [Pliny knew of no stone of the name Lyncurium, **36**, 13.] Chrysolithos? pt., *Plin.*, **37**, 42; Melichrysos? ib., 45; Crateritis? ib., 56. Fig. 6, Pitcairn, N. Y., Pfd. 7, Ural, Kk. 8, N. Carolina. 9, McDowell Co., N. C. 10, Renfrew Co., Canada, Hidden. 11, Cheyenne Mt., Colorado, Hovey. 12, Govt. Tomsk, Kk.

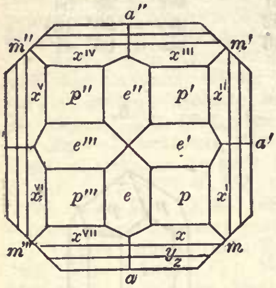
Twins[5]: tw. pl. *e* (101), geniculated twins like those of rutile and cassiterite. Commonly in square prisms, often elongated, sometimes pyramidal, *p* (111), and less often *u* (331), *e* (101); the basal plane rare. Faces of pyramids sometimes convex. Also in irregular forms and grains.

Cleavage: *m* imperfect; *p* (111) less distinct. Fracture conchoidal. Brittle.

H. = 7·5. G. = 4·68–4·70 most common, but varying widely; sometimes much lower, to 4·2, and also higher, to 4·86; density slightly increased by ignition, Church (see below). Luster adamantine. Colorless, pale yellowish, grayish, yellowish green, brownish yellow, reddish brown. Streak uncolored. Transparent to subtranslucent and opaque. Optically +. Double refraction strong. Sometimes abnormally biaxial, cf. Mld.[6] and beccarite (below); also made biaxial by heating, Madelung[6]. Also isotropic and amorphous by alteration. Indices:

Ceylon $\omega_y = 1·9239$ $\epsilon_y = 1·9682$
Miask $\omega_y = 1·9313$ $\epsilon_y = 1·9931$ Sanger[7]

13.



Saualpe, after Haidinger.

**Var.**—1. *Ordinary.* In square prisms, long or short, occasionally very large. Habit and color somewhat variable, see figs. above. Fig. 12 shows the Russian *engelhardite.*

Church (Geol. Mag., **2**, 322, 1875) gives the following determinations of the specific gravity, the numbers in parentheses being the results after prolonged ignition. All the stones were flawless except 2 (transparent but flawed) and 3 (opaque); 1 was slightly opalescent.

| | G. | | G. |
|---|---|---|---|
| 1. *Dark green, dull* | 4·02 | 6. *Brownish yellow* | 4·62 |
| 2. Fredriksvärn, *hair-brown* | 4·489 (4·633) | 7. *Brownish yellow* | 4·679 |
| 3. Henderson Co., N. C., *pale brown* | 4·54 (4·667) | 8. Ceylon, *pale green* | 4·691 |
| | | 9 *Brown* | 4·696 |
| 4. Ceylon, *greenish* | 4·579 (4·625) | 10 Mudgee, N. S. W., *deep red* | 4·705 (4·70) |
| 5. *Yellow* | 4·60 | 11. Expailly, *Jacinth* | 4·863 (4·863) |

Other determinations are as follows: Ceylon, G. = 4·183 (after ignition 4·534) Damour; Stockholm, 4·072–4·222 Svanberg; Renfrew Co., 4·552 Fletcher; Ilmen Mts., 4·599, 4·610 Svanberg; Ceylon, 4·681 id., 4·721 Cowry; Fredriksvärn, 4·2 Berlin; Madison Co., N. C., 4·607 Chandler; Litchfield, Me., 5·7 Gibbs; Grenville, Canada, 4·625–4·602 T. S. Hunt; Templeton, Canada, 4·482, 4·612 Harrington; Reading, Pa., 4·595 Wetherill; Lonedo, Italy, 4·673 Grattarola; Cheyenne Mt., Col., 4·709 Hillebrand. Further for hyacinth-red gems from New South Wales, Liversidge gives: G. = 4·697, 4·719, 4·782 for cut gems; also G. = 4·684 one uncut, weighing 2·46 grams.

*Azorite*, whose true nature has long been in question (see 5th Ed., p. 761, where its possible identity with zircon is suggested), has been proved to be zircon by Osann, who separated material enough for a quantitative analysis, see Jb. Min., **1**, 115, 1887. **1**, 126, 1888. It is in minute tetragonal pyramids, with *m* (110), *p* (110), *u* (331), colorless or of a pale greenish color. Observed in the sanidine-trachyte of São Miguel, one of the Azores; it is implanted in part upon sanidine, in part upon hornblende, and is associated with the still doubtful pyrrhite (see p. 728). Osann shows that the hardness is over 7 (not near fluorite, Teschemacher, nor 5, Schrauf), the specific gravity above 3·6. Osann's determination is confirmed by Ben-Saude (Bull. Soc. Min., **11**, 201, 1888), who gives $\dot{c} = 0·6417$; Hubbard earlier argued for the same conclusion, Ber. nied. Ges., June 7, 1886.

2. *Gem variety. Hyacinth:* the orange, reddish and brownish transparent kinds. The color is often lost on exposure to the light. For specific gravity determinations see above.

*Jargon.* The colorless and yellowish or smoky zircons of Ceylon, named in allusion to the fact that while resembling the diamond in luster, they were comparatively worthless; and thence came the name *zircon.*

**Comp.**—$ZrSiO_4$ or $ZrO_2.SiO_2$ = Silica 32·8, zirconia 67·2 = 100. A little iron ($Fe_2O_3$) is usually present.

An alterėd zircon from the pegmatyte of the Schwalbenberg has been analyzed by Woitschach (Zs. Kr., **7**, 87, 1882), as follows; cf. cyrtolite below.

| $SiO_2$ | $ZrO_2$ | $ThO_2$ | $CeO_2$ | $SnO_2$ | $Y_2O_3$ | $Fe_2O_3$ | CaO | MgO | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|
| 29·16 | 55·28 | 2·06 | *tr.* | 0·57 | 3·47 | 2·96 | 2·14 | 0·34 | 5·02 = 101·10 |

Spezia shows that the color of zircon is due to the state of oxidation of the iron, varying in O.F. and R.F., but this is not the cause of the change of density sometimes noted in ignition (see above). Att. Soc. Tosc., **12**, 37, 1876.

Sorby assumed the presence of a new element, "Jargonium," which is not confirmed by Cochran (l. c.) and others, cf. Ch. News, **20**, 7, 1869; also Proc. Roy. Soc., **17**, 511, 1869, **18**, 197, 1870. Traces of a number of elements have been spectrally identified by Linnemann, Ber. Ak. Wien, **91** (2), 1019 and **92** (2), 427, 1885 (in Ch. News, **52**, 220, etc., 1885); also the absorption lines of erbium (and didymium). The name "*polykrasilith*" (πολὺς, *many*, κράσις, *mixture*) is suggested as appropriate in view of the presence, as believed by the author, of the elements, Sn, Pb, Cu, Bi, Zr, Al, Fe, Co, Mn, Zn, Mg, U, Er, Ca, K, Na, Li.

**Pyr., etc.**—Infusible; the colorless varieties are unaltered, the red become colorless, while dark colored varieties are made white; some varieties glow and increase in density by ignition. Not perceptibly acted upon by salt of phosphorus. In powder is decomposed when fused with soda on the platinum wire, and if the product is dissolved in dilute hydrochloric acid it gives the orange color characteristic of zirconia when tested with turmeric paper. Not acted upon by acids except in fine powder with concentrated sulphuric acid. Decomposed by fusion with alkaline carbonates and bisulphates.

**Obs.**—Occurs in crystalline rocks, especially granular limestone, chloritic and other schists; gneiss, syenite; also in granite; sometimes in iron-ore beds.

*Zircon-syenite* is a coarse syenitic rock, containing crystals of zircon, with ægirite, elæolite, etc. Crystals are common in most auriferous sands. Sometimes found in volcanic rocks, probably in part as inclusions derived from older rocks. Microscopic examination shows it to be a not uncommon constituent of many crystalline rocks. Cf. Rosenb., Mikr. Phys., 310, 1886.

Found in alluvial sands in Ceylon; in the gold regions of the Ural, near Miask, Berezov, Nevyansk, etc.; at Laurvik and Hakedal in Norway; at Arendal, in the iron mines; at Hitterö; at Fredriksvärn, in zircon-syenite; in veins in the augite-syenite of the Langesund fiord; at Bilin in Bohemia; Sebnitz in Saxony; Pfitschthal in Tyrol; in lava at Niedermendig in the Eifel, in red crystals; at Expailly, near Le Puy in France; in Auvergne, in volcanic tufa; at Vesuvius with rhyacolite; with corundum, etc., at Lonedo, northern Italy; in Scotland, at Scalpay, Isle of Harris; at Strontian in Argyleshire; in the auriferous sands of the Croghan Kinshela Mtn., Ireland; in Greenland; at Santa Rosa in Antioquia, U. S. Colombia; in the gold regions of Australia, as at Mudgee, New South Wales, and many other points, especially in the auriferous gravels; also with topaz, and with cassiterite.

In N. America, in *Maine*, at Litchfield; at Mt. Mica in Paris; Greenwood; Hebron. In *Vermont*, at Middlebury. In *Conn.*, at Norwich, with sillimanite, rare; at Haddam (calyptolite) in minute crystals. In *N. York*, at Hall's mine in Moriah, Essex Co., cinnamon-red, in a vein of quartz; near the outlet of Two Ponds, Orange Co., with scapolite, pyroxene, and titanite, in crystals sometimes 1 in. in length; on Deer Hill, 1 m. S.E. of Canterbury, Orange Co., crystals abundant of a deep brownish red or black color, and occasionally 1½ in. in length; at Warwick, at the southern base of Mount Eve, chocolate-brown crystals in limestone and scapolite; near Amity, and also in Monroe and Cornwall, at several localities, of white, reddish brown, clove-brown, and black colors; at Diana in Lewis Co., in large brown crystals sometimes 2 in. long, with titanite and scapolite, rare; in St. Lawrence Co., with apatite, at Robinson's in the town of Hammond, near de Long's Mills, some of the crystals 1½ in. long and ½ in. wide, and occasionally containing a nucleus of carbonate of lime; also at Rossie; at Fine, in large prismatic crystals, of a greenish color; also at Pitcairn (f. 6); at Johnsburg, in Warren Co. In *N. Jersey*, at Franklin; at Trenton in gneiss. In *Penn.*, near Reading, in large crystals in magnetic iron ore; at Easton, in mica slate. In *N. Car.*, in the gold sands of Burke, McDowell, Polk, Rutherford, and other counties; especially abundant in Henderson Co., on the south side of the Blue Ridge near Green river, at the Freeman mine, where it occurs in a disintegrated granitic or gneissoid rock so abundantly that it has been mined in large quantities for technical purposes; up to 1889 this and the Jones mine are said to have yielded 30 *tons* of zircons (Hidden); in magnetite beds of the Unaka Mts.; also at other points. In *Colorado*, with astrophyllite, etc in the Pike's Peak region in El Paso Co.; at Cheyenne Mt., brilliant reddish brown to pink or green crystals (f. 11) in quartz often surrounded with kaolinite. In *California*, in the auriferous gravel of the north fork of the American river, and elsewhere, as at Spring valley, Cherokee, Butte Co.; Eagle Gulch and Rock Island Hill, Plumas Co.; Picayune Flat, Fresno Co.; Navarro R., Anderson valley, Mendocino Co.

In *Canada*, at Grenville, Argenteuil Co., in crystalline limestone, with wollastonite, titanite, graphite; St. Jérôme on the North River in Terrebonne Co.; Mille Isles; abundant and sometimes in very large crystals, with gigantic titanites, in the apatite deposits in Templeton and adjoining townships in Ottawa Co., Quebec; fine crystals, sometimes twins, in the Sebastopol township, Renfrew Co.; very large crystals in Brudenell township, Renfrew Co.; further in North Burgess, Lanark Co ; in syenite on Pic Island, L. Superior. The Renfrew crystals are sometimes upwards of 6 inches in length with a thickness of 2 inches or more.

The name *Hyacinth* was applied by the ancients to a bluish violet stone, regarded as our sapphire, and was derived from a flower (lily) so called of this color. [In modern mineralogy a *hyacinth-color* is reddish orange with a tinge of brown.] Intagli of zircon are common among ancient gems, and the fact that the *lyncurium* of Theophrastus was, as he says, used for engraved signets, while at the same time electric on friction, and often amber-colored, are the principal evidence that it was our zircon.

**Alt.**—Zircon is one of the least alterable of minerals, as it contains no protoxides, and only the most insoluble of dioxides. It, however, passes to a hydrous state, becoming isotropic and amorphous, and this is attended ultimately with a loss of silica and the addition of iron oxide and other impurities derived from infiltrating waters. *Auerbachite, malacon, œrstedite, tachyaphaltite, calyptolite, cyrtolite* (see beyond), are probably altered zircon.

**Artif.**—Formed in crystals by action of silicon chloride on zirconia (Daubrée); by action of silicon fluoride on zirconia, or of zirconium fluoride on quartz, beautiful transparent octahedrons resulting (Deville and Caron).

**Ref.**—[1] Preisschrift, p. 72, 1825. Kk., Min. Russl., **3**, 139, 1858, gives $pp' = 56^\circ\ 39'\ 39''$. Also Dbr., for Miask, $pp' = 56^\circ\ 39'\ 42''$; Pfitschthal, $56^\circ\ 39\ 14''$; Fredriksvärn, $56^\circ\ 39'\ 27''$; Ceylon, $56^\circ\ 40'\ 10''$, Pogg., **107**, 257, 1859.

[2] Cf. Haid., Min. Mohs., **2**, 368, 1825; also Gdt., Index, **3**, 353, 1891. Gehmacher has noted vicinal planes on the Pfitschthal zircons, Zs. Kr., **12**, 50. 1886. Cross and Hillebrand (Colorado, Am. J. Sc., **24**, 284, 1882) note a pyramid $\omega$, with $p\omega = 15^\circ\ 14'$, whence $\omega = 559$ probably, $\omega p = 15^\circ\ 27'$; they suggest the less probable symbol 14·14·25. [3] Hidden, Burgess, ib., **29**, 250, 1885. [4] Brögger, Norway, Zs. Kr., **16**, 103, 1890. [5] Hidden, Am. J. Sc., **21**, 507, 1881, Fletcher, Phil. Mag., **12**, 26, 1881. [6] Ann. Mines, **10**, 143, 1876. Cf. beccarite below and Madelung, Zs. Kr., **9**, 46, 1884. [7] Quoted by Rosenbusch, Mikr. Phys., 311, 1886.

BECCARITE *Grattarola*, Att. Soc. Tosc., **4**, 177, 1879, **7**, Proc. Verb., 82, 1890. A variety of zircon from Ceylon. Color olive-green. Optically biaxial, with apparent twinned structure; a basal section is divided into four sectors in polarized light. Form and other characters like zircon. G. = 6·54, 6·74. Analysis: $SiO_2$ 30·30, $ZrO_2$ 62·16, $Al_2O_3$ 2·52, CaO 3·62, ign. 0·32 = 98·92. Named for Dr. O. Beccari.

**Altered Zircon.**—The following tetragonal zircon-like minerals are in part, at least, altered zircon. They afford more or less water on ignition.

MALACON. Malakon *Scheerer*, Pogg., **62**, 436, 1844. $pp' = 55^\circ\ 3'$ to $55^\circ\ 20'$. H. = 6·5. G. = 3·90–3·91. Luster vitreous to subvitreous. Color brown, powder reddish brown or uncolored. From Hitterö in Norway; and Chanteloube, Haute Vienne, occurring in thin plates, over 3 to 4 mm. thick, and occasionally with crystals on their surface. Named from μαλακός, *soft*. Anal. 1–3 below.

A mineral found with columbite at Rosendal near Björkboda, Finland, has been referred to adelpholite of Nordenskiöld (p. 731), but an analysis by A. E. Nordenskiöld (anal. 7) shows that it is an altered zircon, near malacon or cyrtolite (Öfv. Ak. Stockh., **20**, 452, 1863, Pogg., **122**, 615, 1864).

TACHYAPHALTITE *Weibye*, Pogg., **88**, 160, 1853. Crystals like those of zircon, with forms *m* (110), *a* (100) and two octahedrons. H. = 5·5. G. = 3·6. Luster submetallic to vitreous. Color dark reddish brown. Streak dirty yellow. Subtranslucent. From granite veins in gneiss near Kragerö in Norway with titanite. Named from ταχύς, *quick*, and ἄφαλτος, the mineral flying readily from the gangue when struck.

ŒRSTEDITE *Forchhammer*, Pogg., **35**, 630, 1835. $pp' = 56^\circ\ 43\tfrac{1}{2}'$. H. = 5·5. G. = 3·629. Luster splendent, adamantine. Color reddish brown. From Arendal in Norway, and commonly on crystals of pyroxene. Named after H. Ch. Œrsted (1777–1851).

AUERBACHITE *Hermann*, J. pr. Ch., **73**, 209, 1858. $pp' = 57^\circ\ 17'$ and $pp^{iv} = 94^\circ\ 39'$ Kk. H. = 6·5. G. = 4·06. Luster greasy to vitreous, weak. Color brownish gray. From a siliceous schist, District of Alexandrovsk, Russia. Named after Dr. Auerbach, by whom the crystals were first studied.

Anal.—1, Scheerer, l. c. 2, Damour, Ann. Ch. Phys., **24**, 87, 1848. 3, Hermann, J. pr. Chem., **53**, 32, 1851. 4, J. P. Cooke, l. c. 5, 6, Knowlton, l. c. 7, A. E. Nordenskiöld, l. c. 8, Berlin, Pogg., **88**, 161, 1853. 9, Forchhammer, l. c. 10, Hermann, l. c.

[a] With some FeO. [b] With some $TiO_2$. [c] With trace of manganese. [d] Cerium oxides. [e] $ThO_2$.

CYRTOLITE. Malacon, Altered Zircon, *J. P. Cooke,* Am. J. Sc., **43**, 228, 1867; Cyrtolite *W. J. Knowlton,* ib., **44**, 224. Form a combination of *m* (110) and *e* (101), and resembling a rhombic dodecahedron, the pyramidal faces *e* strongly curved. H. = 5–5·5; after ignition 7–7·5 Cooke. G. = 3·98–4·04 Cooke; 3·85–3·97 Knowlton. Luster somewhat adamantine. Color brownish red; powder the same. From Rockport, Mass., in granite, with danalite and cryophyllite. Named from *κύρτος, bent.* See analyses 4–6 above.

A mineral regarded as related to cyrtolite by *Nordenskiöld* (G. För. Förh., **3**, 229, 1876) has the following characters: In tetragonal crystals, *m* (110) and *e* (101), resembling a rhombic dodecahedron. Color yellow to yellowish brown. Translucent. H. = 5·5–6. G. = 3·29. Analysis:

| $SiO_2$ | $ZrO_2$ | $Er_2O_3,Y_2O_3$ | $Ce_2O_3$ | CaO | MgO | $H_2O$ | $Al_2O_3$ | FeO | |
|---|---|---|---|---|---|---|---|---|---|
| 27·66 | 41·78 | 8·49 | 3·98 | 5·06 | 1·10 | 12·07 | *tr.* | *tr.* | = 100·14 |

Occurs with fergusonite, arrhenite, xenotime, at Ytterby, Sweden.

An analysis by Blomstrand (Ak. H. Stockh., Bihang, **12** (2), No. 10, 1886) of the same mineral from Ytterby gave:

| $SiO_2$ | $ZrO_2$ | $Y_2O_3$[a] | FeO | CaO | MgO | CuO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| $\frac{4}{4}$ 26·93 | 41·17 | 10·93 | 1·51 | 5·85 | *tr.* | 0·17 | 0·89 | 12·55 | Cerium earths *tr.* = 100 |

[a] $Y_2O_3$ = Yttrium earths.

The name *anderbergite* is proposed for the mineral, but as noted by Bäckström (Zs. Kr., **15**, 83, 1888) it is undoubtedly only a pseudomorph, and belongs with the uncertain minerals called cyrtolite.

A mineral having the external aspect of cyrtolite occurs rather abundantly in crystalline aggregates and massive, at Branchville, Conn.; also in Mitchell and Henderson counties, N. Carolina; further similarly and in large quantities in Llano Co., Texas (G. = 3·652) with gadolinite and other rare species. It has not been analyzed, and while probably altered and hydrated it seems probable that the original mineral may have been a more complex species than ordinary zircon. Cf. alvite below; also anal. by Woitschach, quoted on p. 485.

A mineral from the feldspar quarries at Alve near Arendal gave Lindström:

| $SiO_2$ | X[a] | $ZrO_2$ | PbO | $Fe_2O_3$ | $Y_2O_3$[b] | $Ce_2O_3$[c] | BeO[d] | MnO | CaO | MgO | ign. | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 26·10 | 2·78 | 32·48 | 0·45 | 5·51 | 1·03 | 3·27 | 14·73 | 0·27 | 2·44 | 1·05 | 8·84 | $UO_3$ *tr.* = 98·95 |

[a] Metallic acids. [b] Yttrium earths. [c] Cerium oxides. [d] Incl. $Al_2O_3$ in small amount.

This is called *alvite* by Nordenskiöld, who quotes the above analysis (G. För. Förh., **9**, 28, 1887). He regards the anderbergite of Blomstrand as taking the place in the pegmatyte veins of southern Norway of the alvite of the Arendal region. The original alvite was described as follows:

ALVITE *D. Forbes & T. Dahll,* Nyt Mag., 8, 228, 1855. Tetragonal. Crystals like those of zircon. H. = 5·5. G. = 3·601 Alve; 3·46 Helle. Luster greasy. Color reddish brown, becoming grayish brown by alteration. Subtranslucent to opaque. A very small portion, somewhat altered, afforded:

| $SiO_2$ | $ThO_2$? | $ZrO_2$ | $Y_2O_3$ | $Ce_2O_3$ | $Al_2O_3$,BeO | $Fe_2O_3$ | CaO | $H_2O$ | $SnO_2$,CuO | |
|---|---|---|---|---|---|---|---|---|---|---|
| 20·33 | 15·13 | 3·92 | 22·01 | 0·27 | 14·11 | 9·66 | 0·40 | 9·32 | *tr.* | = 95·15 |

Yields water B.B., but is infusible; with the fluxes reacts for iron but not for titanium. Insoluble in acids. From Helle and Narestö in Norway, with feldspar and black mica.

A mineral from the granite of Devil's Head Mt., Douglas Co., Colorado, in the Pike's Peak region has been analyzed by Hillebrand (Proc. Soc. Col., 3, 44, 1888). Occurs in tapering indistinctly crystalline forms. Color brown. G. = 3·60 (1), 3·70 (2), 3·64 (3). It is spoken of as "an ill-defined zirconium-mineral," allied to cyrtolite. Sections show the presence of limonite as impurity.

| | $SiO_2$ | $ZrO_2$[a] | $Ce_2O_3$[b] | $Er_2O_3$ | $Y_2O_3$ | $Fe_2O_3$ | MnO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ | $P_2O_5$ | F |

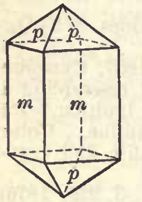
[a] Incl. $SnO_2$,$Ta_2O_5$: in 1, 0·03 $SnO_3$, 0·71 $Ta_2O_5$. [b] Incl. $ThO_2$ and $(Di,La)_2O_3$: in 2, 1·16 $ThO_2$, 0·06 $Ce_2O_3$, 0·19 $(Di,La)_2O_3$. [c] Incl. 0·11 MgO. [d] 0·13 MgO.

**395. THORITE.** Thorit *Berz.*, Ak. H. Stockh., p. 1, 1829. Orangit *Bergemann*, Pogg., **82**, 561, 1851. Uranothorite *P. Collier*, J. Am. Ch. Soc., **2**, 73, 1880. Torit.



Norway; Bgr.

Tetragonal. Axis $\dot{c}$ = 0·6402. In square prisms *m* (110, *I*), with pyramid *p* (111, 1), also the zirconoid *z* (311, 33); *pp'* = 56° 40' Breithaupt.[1] The form resembles that of zircon. Also massive and compact.

Cleavage: *m* distinct. Fracture conchoidal. Brittle. H. = 4·5–5. G. = 5·19–5·40 orangite; 4·4–4·8 thorite. Luster of surface of fresh fracture vitreous to resinous; in part greasy. Color orange-yellow, brownish yellow; also black, inclining to brown. Streak light orange to dark brown. Transparent in thin splinters to nearly opaque. Optically uniaxial, positive, when unaltered, but becoming isotropic and amorphous.

**Var.**—1. *Thorite.* As originally described, occurs in black octahedral crystals (called isometric by Dufrenoy). G. = 4 630 Berz.; 4·686 Bergemann; 4·344–4·397 Chydenius. First found on the island Lövö, opposite Brevik. Later found in large crystals near Arendal.

2. *Orangite.* In bright orange-yellow tetragonal crystals, near zircon in angle; also massive, first described from the Brevik region. G. = 5·397 Bergemann; 5·34 Krantz; 5·19 Damour; 4·888–5·205 Chydenius. Sometimes forms the kernel of a crystal externally altered to thorite. Supposed by Bergemann to contain a new metal called by him *donarium.* See p. 1050,

The zircon-like tetragonal form was first recognized by Zschau[1], and more accurate measurements were later made by Breithaupt. The identity of thorite and orangite was early proved, and later it was shown that both were undoubtedly altered hydrous forms of an anhydrous thorium silicate isomorphous with zircon.

3. *Uranothorite.* Massive. Fracture subconchoidal. H. = 5. G. = 4·126. Luster resinous to subvitreous Color dark red-brown. Streak yellow-brown. B.B. infusible. From the Champlain iron region, N. Y., exact locality unknown (anal. 5); also a similar variety from Norway. anal. 3, 4.

**Comp.**—Originally anhydrous thorium silicate, $ThSiO_4$ or $ThO_2.SiO_2$ = Silica 18·5, thorina 81·5 = 100. All analyses show water, and sometimes uranium.

**Anal.**—1, Damour, C. R., **34**, 685, 1852, Ann. Mines, **1**, 587, 1852. Also incomplete analyses by Bergemann, Chydenius. 2, Berzelius, Ak. H. Stockh., p. **1**, 1829, also Pogg., **15**, 633, 1829 (the latter with the anal. in slightly different form). 3, Lindström, G. För. Förh., **5**, 500, 1881. 4, Nordenskiöld, ib., **3**, 228, 1876. 5, Parsons, quoted by Collier, J. Am. Ch. Soc., **2**, 73, 1880.

[a] Incl. 0·28 $Mn_2O_3$. [b] Incl. 2·39 $Mn_2O_3$. [c] Incl. 0·14 $K_2O$. [d] 0·14 $K_2O$.
[e] Incl. $Y_2O_3$. [f] $K_2O$ 0·18. [g] $UO_3$.

Composition discussed by Nilson, Öfv. Ak. Stockh., **39**, No. 7, 3, 1887. Investigation of absorption-lines, didymium chiefly, also erbium, samarium, thulium, etc., Krüss and Nilson, Öfv. Ak. Stockh., **44**, 364, 1887.

**Pyr., etc.**—In the closed tube yields water; the orange variety becomes dull brown, and, on cooling, orange again. B.B. on charcoal infusible, the edges only being slightly glazed; with borax a yellowish pearl, becoming colorless on cooling; with salt of phosphorus a colorless glass, which becomes milky and greenish on cooling; with borax an orange glass when hot, which becomes grayish on cooling. A little niter being added, the orange color remains after cooling.

With hydrochloric acid easily forms a jelly before, but not after, calcination. The black thorite becomes pale brownish red when heated; and on charcoal forms a yellowish brown slag.

**Obs.**—Found by Esmark in the augite-syenite on the island Lövö, opposite Brevik in Norway; also at other points on the Langesund fiord, as Barkevik, on Haö, Sigtesö, Arö. Masses of orangite weighing several ounces have been obtained. In large black crystals at Garta, Bjellan, the island Landbö, and other points near Arendal, from whence it has been obtained in large quantities. At Linland on the Lenes fiord near Lindesnäs with alvite and magnetite, both the black thorite and orangite; also at Svenör, the reddish brown variety.

A mass of a dark red-brown color (*uranothorite*) has been found in the Champlain iron region in northern New York; exact locality unknown.

**Ref.**—[1] See Zschau, Am. J. Sc., **26**, 359, 1858; B. H. Ztg., **25**, 114, 1866; Nd., Öfv. Ak. Stockh., **27**, 554, 1870, G. För. Förh., **3**, 226, 1876.

On the optical structure of the more or less altered forms, see Bgr., Zs. Kr., **16**, 116, 1890.

CALCIOTHORITE *W. C. Brögger*, G. För. Förh., **9**, 258, 1887; Zs. Kr., **16**, 127, 1890. Massive. Fracture conchoidal. Brittle. H. = 4·5. G. = 4·114 Cleve. Luster vitreous. Color deep red, resembling almandite garnet. Translucent. Optically isotropic, amorphous.

Composition: $5ThSiO_4.2Ca_2SiO_4 + 10H_2O$. Anal.—Cleve:

| $SiO_2$ | $ThO_2$ | $Ce_2O_3$ | $Y_2O_3$ | $Al_2O_3$ | $Mn_2O_3$ | CaO | MgO | $Na_2O$ | ign. |
|---|---|---|---|---|---|---|---|---|---|
| 21·09 | 59·35 | 0·39 | 0 23 | 1·02 | 0·73 | 6·93 | 0·04 | 0·67 | 9·39 = 99·84 |

B.B. becomes white but does not fuse. Gives off water. Gelatinizes with acid.

Found in reniform masses, as large as walnuts, embedded in analcite (derived from elæolite) and in feldspar on the islands Låven and Arö in the Langesund fiord, Norway.

EUCRASITE. Eukrasit *S. R. Paijkull*, G. För. Förh., **3**, 350, 1877. Fracture uneven. Brittle. H. = 4·5–5. G. = 4·39. Luster greasy. Color blackish brown. Streak brown. Slightly translucent in thin splinters. Optically isotropic, amorphous (Bgr., Zs., **16**, 129, 1890). Analysis:

| $SiO_2$ | $ThO_2$ | $TiO_2$ | $SnO_2$? | $ZrO_2$ | $MnO_2$ | $CeO_2$ | $Ce_2O_3$ | $Y_2O_3$ | $Er_2O_3$ | $Fe_2O_3$ | CaO | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 16·20 | 35·96 | 1 27 | 1·15 | 0·60 | 2·34 | 5·48 | 8·55[a] | 4·33 | 1·62 | 6·02[b] | 4·95[c] | 2 59[d] | 9·15 = 100·21 |

[a] Incl. 2·42 $(La,Di)_2O_3$. [b] Incl. $Al_2O_3$ 1·77. [c] MgO 0·95. [d] $K_2O$ 0·11.

B.B. fusible (at 4) on the edges. The borax bead in the R. F. is violet, in the O. F. yellow. In hydrochloric acid partially soluble, with the evolution of chlorine. Completely soluble in sulphuric acid. Occurs near Barkevik, Langesund fiord, Norway. Named from εὖ, *well*, and κρᾶσις, *mixture*, because so complex in composition.

FREYALITE *Esmark; Damour*, Bull. Soc. Min., **1**, 33, 1878. Resembles some brown thorite. Scratches glass slightly. G. = 4·06–4·17. Color brown. Streak yellowish gray. Translucent in thin splinters. Luster resinous. An approximate analysis by Damour gave:

| $SiO_2$ | $ThO_2$ | $Ce_3O_4$ | $(La,Di)_2O_3$ | $Al_2O_3(ZrO_2?)$ | $Fe_2O_3$ | $Mn_3O_4$ | Alk. | $H_2O$ | ign. |
|---|---|---|---|---|---|---|---|---|---|
| 20·02 | 28·39 | 28·80 | 2·47 | 6·31 | 2·47 | 1·78 | 2·33 | 7·40 | 0·82 = 100·79 |

B B. swells up but does not fuse. In the closed tube decrepitates, gives off water, and becomes white. With salt of phosphorus in R. F. dissolves, forming an opal-like glass, which in O. F. becomes brown, and on cooling is colorless and translucent. With borax in O. F. gives a transparent brown bead, becoming almost colorless on cooling, and showing in the spectroscope an absorption band on the border of the red and orange (Di). Dissolves readily in acid, giving gelatinous silica. With hydrochloric acid chlorine is given off.

From the neighborhood of Brevik (Barkevik), Norway. Named for the Scandinavian goddess, Freya.

AUERLITE *W. E. Hidden* and *J. B. Mackintosh*, Am. J. Sc., **36**, 461, 1888.

Tetragonal. Form a square prism with pyramid, resembling zircon in habit and angles. H. = 2·5–3. G. = 4·42–4·77. Luster resinous. Color dull yellowish white to dark orange-red. Translucent to opaque.

Analysis:—

| $SiO_2$ | $P_2O_5$ | $ThO_2$ | $H_2O,CO_2$ | $Fe_2O_3$ | CaO | MgO | $Al_2O_3$($ThO_2$ *tr.*) | |
|---|---|---|---|---|---|---|---|---|
| 7·64 | 7·46 | 70·13 | 11·21 | 1·38 | 0·49 | 0·29 | 1·10 | = 99·70 |

Other trials gave: $SiO_2$ 9·25, 8·25, $P_2O_5$ 7·59, $ThO_2$ 69·23, $Fe_2O_3$ 1·42, $H_2O$ 10·7, 9·88, $CO_2$ 1·00.

This is interpreted as corresponding to a silico-phosphate of thorium, $ThO_2.(SiO_2.\frac{1}{3}P_2O_5) + 2H_2O$. It cannot be regarded as certain, however, that the phosphoric acid belongs to the original mineral, which as found is certainly more or less altered. It is to be noted, in this connection, that parallel intergrowths of zircon and auerlite are described, and others of zircon and the phosphate, xenotime, are not uncommon; also further, that silica is commonly present in the phosphate, monazite, and sometimes in small amount in xenotime. That it really belongs to the constitution of the mineral in these cases has been seriously questioned.

B.B. infusible; becomes brown on ignition, but turns orange again on cooling.

Occurs in disintegrated granite or gneiss, in Henderson Co., N. C.; the localities are the Freeman mine, Green River, and on Price land 3 miles southwest; it is associated with zircon, and sometimes implanted upon it in parallel position.

Named for Dr. Carl Auer von Welsbach.

## 11. Danburite-Topaz Group. Orthorhombic.

$$\overset{\text{II}}{R}\overset{\text{III}}{R}_2(SiO_4)_2 \text{ or } (\overset{\text{III}}{R}O)\overset{\text{III}}{R}SiO_4.$$

| | | | |
|---|---|---|---|
| 396. **Danburite** | $CaB_2(SiO_4)_2$ | | $\breve{a} : \bar{b} : \acute{c} = 0·5444 : 1 : 0·4807$ |
| 397. **Topaz** | $(Al(O,F_2))AlSiO_4$ | | $\breve{a} : \bar{b} : \acute{c} = 0·5285 : 1 : 0·4770$ |
| 398. **Andalusite** | $(AlO)AlSiO_4$ | | $\tfrac{1}{2}\bar{b} : \breve{a} : \tfrac{2}{3}\acute{c} = 0·5070 : 1 : 0·4749$ <br> or $\breve{a} : \bar{b} : \acute{c} = 0·9861 : 1 : 0·7025$ |
| 399. **Sillimanite** | $Al_2SiO_5$ | Orthorhombic | $\breve{a} : \bar{b} = 0·970 : 1$ |
| 400. **Cyanite** | $Al_2SiO_5$ | Triclinic | |

$\breve{a} : \bar{b} : \acute{c} = 0·8994 : 1 : 0·7090$; $\alpha = 90° 5\tfrac{1}{2}'$, $\beta = 101° 2'$, $\gamma = 105° 44\tfrac{1}{2}'$.

The close resemblance in angle and habit between Danburite and Topaz, and further the relation in form between Topaz and Andalusite (though less close), make it probable that Groth's formulas for the two last mentioned species, given above, should be accepted, and that they should be included with Danburite in a single group of orthosilicates. To Sillimanite the same formula as that of Andalusite probably belongs (Groth, Clarke), while Cyanite is uncertain; Groth regards it as a basic metasilicate $(AlO)_2SiO_3$ instead of a basic orthosilicate.

**396. DANBURITE.** *Shepard*, Am. J. Sc., 35, 137, 1839.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0·544444 : 1 : 0·480739$ E. S. Dana[1].

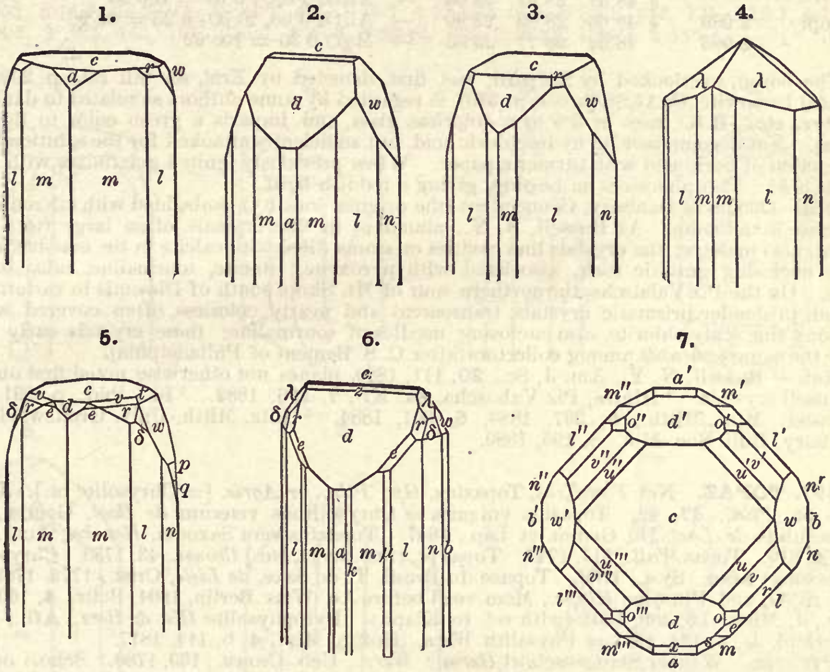
Habit prismatic, resembling topaz. Also in indistinct embedded crystals, and disseminated masses.

Cleavage: *c* very indistinct. Fracture uneven to subconchoidal. Brittle. H. = 7–7·25. G. = 2·97–3·02. Color pale wine-yellow to colorless, yellowish white, dark wine-yellow, yellowish brown. Luster vitreous to greasy, on crystal surfaces brilliant. Transparent to translucent. Streak white.



Figs. 1–3, 5–7, Russell, N. Y. 4, Switzerland, after Hintze.

Ax. pl. ‖ *c*. Optically −, and $Bx_a \perp b$ for red, yellow, green; optically +, and $Bx_a \perp a$ for blue. Ax. angles for Russell, E. S. D.[1]; for Danbury, Dx.[6]; for Switzerland, Hintze[2].

Russell:

For Li $2H_{a.r} = 100° 33'$ $2H_{o.r} = 106° 35'$ ∴ $2V_{a.r} = 87° 37'$ $\beta_r = 1·634$

Na $2H_{a.y} = 101° 30'$ $2H_{o.y} = 105° 36'$ ∴ $2V_{a.y} = 88° 23'$ $\beta_y = 1·637$

$CuSO_4$ $2H_{o.bl} = 104° 36'$ $2H_{a.bl} = 102° 13'$ ∴ $2V_{o.bl} = 90° 56'$ $\beta_{bl} = 1·646$

Danbury: $2H_r = 99° 16'–100° 30'$ $2H_y = 100° 20'–101° 2'$ $2H_{bl} = 101° 42'–102° 16'$

Switzerland:

For Li $2H_{a.r} = 101° 1'$ $2H_{o.r} = 105° 56'$ ∴ $2V_{a.r} = 88° 4'$ $\beta_r = 1·6283$

Na $2H_{a.y} = 101° 46'$ $2H_{o.y} = 105° 38'$ ∴ $2V_{a.y} = 88° 29'$ $\beta_y = 1·6342$

Tl $2H_{a.gr} = 102° 48'$ $2H_{o.gr} = 104° 44'$ ∴ $2V_{a.gr} = 89° 14'$ $\beta_{gr} = 1·6383$

$CuSO_4$ $2H_{o.bl} = 104° 18'$ $2H_{a.bl} = 103° 15'$ ∴ $2V_{o.bl} = 90° 24'$

Also measured $\beta_r = 1·6303$ $\beta_y = 1·6337$ $\beta_{gr} = 1·6366$

" " $\gamma_r = 1·6331$ $\gamma_y = 1·6363$ $\gamma_{gr} = 1·6393$

" calculated $\alpha_r = 1·6258$ $\alpha_y = 1·6317$ $\alpha_{gr} = 1·6356$

**Comp.**—$CaB_2Si_2O_8$ or $CaO.B_2O_3.2SiO_2$ = Silica 48·8, boron trioxide 28·4, lime 22·8 = 100.

The boron, overlooked by Shepard, was first detected by Erni, see 5th Ed., p. 299. The doubtful barsowite, $CaAl_2Si_2O_8$ (see p. 340), is regarded by some authors as related to danburite.

**Pyr., etc.**—B.B. fuses at 3·5 to a colorless glass, and imparts a green color to the O. F. (boron). Not decomposed by hydrochloric acid, but sufficiently attacked for the solution to give the reaction of boric acid with turmeric paper. When previously ignited gelatinizes with hydrochloric acid. Phosphoresces on heating, giving a reddish light.

**Obs.**—Occurs at Danbury, Connecticut (the original locality), embedded with microcline and oligoclase in dolomite. At Russell, N. Y., abundant in fine crystals, often large (to 4 in. in length), also massive; the crystals line cavities or seams filled with calcite in the massive mineral or the enclosing granitic rock, associated with pyroxene, titanite, tourmaline, mica, quartz, pyrite. On the Piz Valatscha, the northern spur of Mt. Skopi south of Dissentis in eastern Switzerland, in slender prismatic crystals, transparent and nearly colorless, often covered with or enclosing fine scaly chlorite, also enclosing needles of tourmaline; these crystals early passed under the name *bementite* among collectors (after C. S. Bement of Philadelphia).

Grünhut[2] adds the following vicinal planes (in addition to some included in the tabulated list above), all in the prismatic zone: 𝔪 (50·53·0), 𝔫 (25·28·0), 𝔬 (25·36·0), 𝔭 (25·41·0), 𝔮 (25·43·0), 𝔩 (25·49·0), 𝔳 (4·21·0). Cf. also Feist, Zs. Kr., **12**, 434, 1886.

The following forms, mostly rare or doubtful, have been noted on Mexican topaz[3]. That all the apparent planes observed on the curiously modified edges of these crystals deserve crystallographic symbols seems to the author very improbable; it is to be noted that in many cases *all* the pyramidal edges of a crystal show similar replacements, sometimes single, often double.

Crystals commonly prismatic, *m* predominating; or *l* (120) and the form then a nearly square prism resembling andalusite. Faces in the prismatic zone often vertically striated, and often showing vicinal planes. Sometimes apparently hemimorphic. Also firm columnar; granular, coarse, or fine.

Cleavage: *c* highly perfect; also very imperfect ∥ *d* (201) and *f* (021) as shown by the percussion figures (Mgg.[4]). Fracture subconchoidal to uneven. Brittle.

H. = 8. G. = 3·4–3·65. Luster vitreous. Color straw-yellow, wine-yellow, white, grayish, greenish, bluish, reddish. Streak uncolored. Transparent to subtranslucent.

Optically +. Ax. pl. ∥ *b*. Bx ⊥ *c*. Axial angles very variable in crystals from different localities and even in plates from the same crystal. Cf. Dx. and Mld.[6]; the latter regards topaz as pseudo-orthorhombic and monoclinic. Refractive indices and axial angles[5]:

Brazil, Dx.:

$\alpha_y = 1{\cdot}6120$ $\beta_y = 1{\cdot}6150$ $\gamma_y = 1{\cdot}6224$ $\therefore$ $2V_y = 65°\ 14'$ $2E_y = 121°\ 1'$
$\alpha_{gr} = 1{\cdot}6149$ $\beta_{gr} = 1{\cdot}6174$ $\gamma_{gr} = 1{\cdot}6236$ $\therefore$ $2V_{gr} = 65°\ 3'$ $2E_{gr} = 120°\ 49'$
Also measured (1) $2E_y = 120°\ 40'$ (2) $2E_r = 113°\ 50'$ $2E_{bl} = 112°\ 27'$
" " $2E_y = 72°, 81°\ 30', 90°$.

Again, Feussner:

$\alpha_y = 1{\cdot}61559$ $\beta_y = 1{\cdot}61808$ $\gamma_y = 1{\cdot}62510$ $\therefore$ $2V_y = 61°\ 47'$ $2E_y = 112°\ 20'$

Schneckenstein, Dx.:

$\alpha_r = 1{\cdot}61400$ $\beta_r = 1{\cdot}61644$ $\gamma_r = 1{\cdot}62320$ $\therefore$ $2V_r = 62°\ 12'$ $2E_r = 113°\ 14'$
$\alpha_{gr} = 1{\cdot}61835$ $\beta_{gr} = 1{\cdot}62071$ $\gamma_{gr} = 1{\cdot}62740$ $\therefore$ $2V_{gr} = 61°\ 37'$ $2E_{gr} = 112°\ 12'$
Measured $2E_r = 114°\ 13'$ $2E_r = 113°\ 38'$

Nerchinsk, Mühlheims:

| | $\alpha$ | $\beta$ | $\gamma$ | | 2V (calc.) | 2V (meas.) |
|---|---|---|---|---|---|---|

| Schneckenstein: | | | | | | |
| For D | 1·61549 | 1·61809 | 1·62500 | ∴ | 63° 19′ | 62° 33′ |
| Also Brazil: | | | | | | |
| For D | 1·62936 | 1·63077 | 1·63747 | ∴ | 49° 31′·3 | 49° 37′ |

**Var.**—1. *Ordinary.* In prismatic crystals usually colorless or pale yellow, less often pale blue, pink, etc. Sometimes apparently hemimorphic, though not so in fact. The color of some deep wine-yellow Russian crystals fades out on exposure to the daylight; the yellow of the Brazilian crystals is changed by heating to a pale rose-pink.

Church obtained for white flawless Brazilian crystals: G. = 3·571, 3·572, 3·585, 3·595, 3·597; wine-yellow G. = 3·539, and after ignition 3·533; sky-blue G. = 3·541.

*Physalite*, or *pyrophysalite*, is a coarse nearly opaque variety, in yellowish white large crystals from Finbo; it intumesces when heated, and hence its name from φυσαλίς, *bubble*, and πῦρ, *fire*.

2. *Pycnite.* Structure columnar, but very compact. Has been considered a distinct species on the ground of composition and crystallization (made monoclinic by Forchhammer). But Rose made out that the cleavage was the same, and the form probably the same; and Des Cloizeaux showed that the optical characters were those of topaz. Finally Rammelsberg's analysis (11) gives the same composition. Named from πυκνός, *thick*.

**Comp.**—$(Al(O,F_2))AlSiO_4$ Groth. The ratio of O : 2F = 5 : 1, whence the empirical formula $Al_{12}Si_6O_{25}F_{10}$ = Silicon 15·5, aluminium 29·9, fluorine 17·6, oxygen 36·9 = 100, or Silica 33·3, alumina 56·5, fluorine 17·6 = 107·4, deduct (O = 2F) 7·4 = 100.

The oxygen equivalent of the fluorine (= 6 to 7 p. c.) is to be deducted.

**Pyr., etc.**—B.B. infusible. Fused in the closed tube, with previously fused and pulverized salt of phosphorus, etches the glass, giving off silicon fluoride which forms a ring of $SiO_2$ above. With cobalt solution the pulverized mineral gives a fine blue on heating. Only partially attacked by sulphuric acid.

A variety of topaz from Brazil, when heated, assumes a pink or red hue, resembling the Balas ruby.

**Obs.**—Topaz usually occurs in gneiss or granite, with tourmaline, mica, and beryl, occasionally with apatite, fluorite, and cassiterite; also in talcose rock, as in Brazil, with euclase, etc., or in mica slate. With quartz, tourmaline, and lithomarge, forms the topaz rock of Werner (*topazosème*, Haüy). Less frequently it occurs in cavities in rhyolyte and similar volcanic rocks.

Topaz often contains inclusions of liquid carbon dioxide. Minute crystals of three or four different kinds, and two or three kinds of liquids, were detected by Brewster in crystals of topaz, Edinb. Trans., **10**, and later Edinb. N. Phil. J., **16**, 130, Proc. R. Soc. Edinb., **4**, 548, **5**, 95. For later observations see Hartley, J. Ch. Soc., **31**, 241, 1877: Erhard and Stelzner, Min. Mitth., **1**, 450, 1878; also Nd., Jb. Min., **1**, 242, 1886. Crystals from San Luis Potosi are sometimes red with enclosed rutile.

Fine topaz comes from the Urals, from Alabashka, not far from Mursinka in the region of Ekaterinburg; from Miask in the Ilmen Mts.; also the gold-washings on the R. Sanarka, in Govt. Orenburg; in Nerchinsk, beyond L. Baikal, in the Adun-Chalon Mts., etc., one crystal from near the river Urulga, now in the imperial cabinet at St. Petersburg, being 11⅝ in. long, 6½ in. broad; weighing 22½ lbs. av., and magnificent also in its perfect transparency and wine-yellow color. Found also in Kamshatka, of yellow, green, and blue colors; in the province of Minas Geraes, Brazil, at Ouro Preto and Villa Rica, of deep yellow color, either in veins or nests in lithomarge, or in loose crystals or pebbles; at the tin mines of Schlackenwald, Zinnwald, and Ehrenfriedersdorf, and smaller crystals at Schneckenstein and Altenberg; sky-blue crystals in Cairngorm, Aberdeenshire; the Mourne mountains, Ireland, small limpid crystals with beryl, albite and mica, in drusy cavities in granite; and St. Michael's Mount, Cornwall; on the island of Elba, in cavities in the granite of San Piero. *Physalite* occurs in crystals of great size, at Fossum, Norway; Finbo, Sweden, in a granite quarry, and at Broddbo in a boulder; one crystal from this last locality, at Stockholm, weighed eighty pounds. *Pycnite* is from the tin mine of Altenberg in Saxony; also those of Schlackenwald, Zinnwald in Bohemia, and Kongsberg in Norway.

Topaz occurs also in the Mercado Mtn., in Durango, Mexico, along with cassiterite, magnetite, and durangite; at La Paz, province of Guanajuato; at San Luis Potosi in rhyolyte, sometimes enclosing rutile. At Hauneib in Damaraland in Southwest Africa (Hintze, Zs. Kr., **15**, 505, 1889). At Mt. Bischoff, Tasmania, with tin ores; also similarly in New South Wales. In Japan in pegmatyte from Otani-yama, Province of Omi, near Kioto; at Nakatsu-gawa, Province of Mino.

In the United States, in *Maine*, at Stoneham, in albitic-granite in fine clear crystals, also in coarse crystals of great size; it is associated with beryl, columbite, fluorite, triplite, etc. In *Conn.*, at Trumbull, with fluorite and diaspore in small yellow or clear white crystals, also in others large and coarse; at Middletown rare; at Willimantic, with columbite. In *N. Car.*, at Crowder's Mountain. In *Colorado*, in fine crystals colorless or pale blue from the Pike's Peak region, sometimes implanted with phenacite upon amazonstone, also with zircon, smoky quartz, etc.; at Nathrop, Chaffee Co., in wine colored crystals with spessartite in lithophyses in rhyolyte; also similarly in minute crystals in the rhyolyte of Chalk Mt. In *Utah*, in fine transparent colorless crystals with quartz and sanidine in the rhyolyte of the Thomas Range, 40 miles north of Sevier Lake.

The name topaz is from τοπάζιος, an island in the Red Sea, as stated by Pliny. But the topaz of Pliny was not the true topaz, as it "yielded to the file." Topaz was included by Pliny and earlier writers, as well as by many later, under the name *chrysolite*.

**Alt.**—Topaz is found altered both to steatite, and kaolin or lithomarge. Alteration, especially of large opaque crystals, is not uncommon; thus in Saxony and Bohemia, at Kårarfvet, Falun, Sweden, also at Trumbull and Stoneham. The usual result is the change to damourite. Cf. Clarke and Diller, Am. J. Sc., **29**, 378, 1885. The pure Stoneham topaz gave anal. 9, above; a surrounding greenish layer (1) below, and an outside purple zone (2), Whitfield, ibid.; the final product is damourite, anal. 3; Chatard, ib., 28, 22, 1884. Cf. also Atterberg, G. För. Förh., **2**, 402, 1875.

| | | G. | $SiO_2$ | $Al_2O_3$ | F | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ | |

**Artif.**—Obtained by Friedel and Sarasin by the action of hydrofluosilicic acid on silica and alumina in the presence of water at 500°.

**Ref.**—[1] Ural, Min. Russl., **2**, 198, 1854. Note that ć of Kk. and many authors = 2ć Dana, and earlier of Mohs, Naumann, etc.; Grünhut proposed a new position to show relation to andalusite, which, however, is not to be recommended. The axial ratio varies somewhat widely for crystals from different localities, cf. Breith., Handb., **3**, 725 *et seq.*, 1847; Groth, Zs. G. Ges., **22**, 381, 1870; Grünhut, Zs. Kr., **9**, 124, 1884.

[2] See Grünhut, l. c., for list with authorities, also original observations. A recent critical summary, with literature, etc., is given by Gdt., Index, **3**, 223, 1891; cf. earlier, Rose, Reis, Ural, **2**, 80, 1842 *et al.;* Kk., l. c., also **3**, 195, 378, 1858; Mlr. Min., 353, 1852; Dx., Min., **1**, 470, 1862. Groth, Altenberg, Schlackenwald, l. c.; Btd., Framont, Zs. Kr., **1**, 297, 1877; Lasp., Saxony, Bohemia, ib., p. 347; Rath, Mt. Usually in coarse prismatic forms, the prisms nearly square in form. Massive, imperfectly columnar; sometimes radiated and granular.

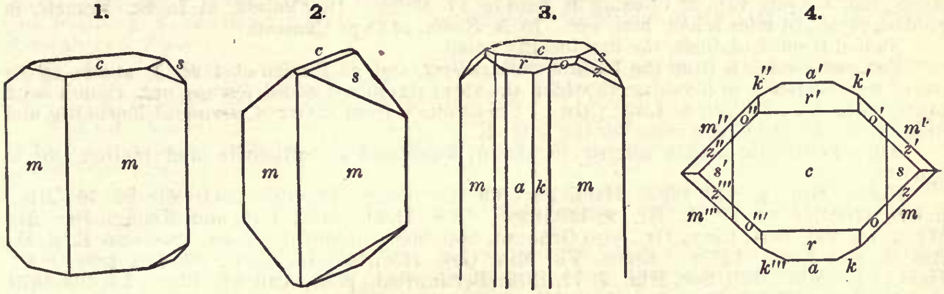
Cleavage: *m* distinct, sometimes perfect (Brazil); *a* less perfect; *b* in traces. Fracture uneven, subconchoidal. Brittle. H. = 7·5. G. = 3·16–3·20. Luster vitreous; often weak. Color whitish, rose-red, flesh-red, violet, pearl-gray, reddish-brown, olive-green. Streak uncolored. Transparent to opaque, usually subtranslucent.

Pleochroism strong in some colored varieties: $\mathfrak{c}$ (= $\breve{a}$) olive-green, $\mathfrak{b}$ (= $\bar{b}$) olive-green, $\mathfrak{a}$ (= $\acute{c}$) blood-red to rose-red. Absorption strong, $\mathfrak{a} > \mathfrak{b} > \mathfrak{c}$. Sections normal to an optic axis are idiophanous[4] or show the polarization brushes distinctly. Optically —. Ax. pl. ∥ *b*. Bx ⊥ *c*. Axial angles:

Brazil $\alpha_r = 1{\cdot}632$ $\beta_r = 1{\cdot}638$ $\gamma_r = 1{\cdot}643$ $\therefore$ $2V_r = 84° 30'$ Dx.
" $2H_{a.r} = 96° 30'$ $2H_{o.r} = 113°$ $\therefore$ $2V_r = 83° 37$ Dx $2H_a = 96° 33$ Btd.



Figs. 1, 2, Common forms. 3, 4, Upper Providence, Delaware Co., Penn.

**Var.**—1. *Ordinary.* H. = 7·5 on the basal face, if not elsewhere. Crystals coarse, square prismatic in form, often soft on the surface from incipient alteration.

2. *Chiastolite* or *Macle.* Stout crystals having the axis and angles of a different color from the rest, owing to a regular arrangement of carbonaceous impurities through the interior, and hence exhibiting a colored cross, or a tesselated appearance in a transverse section. H. = 3–7·5, varying much with the degree of impurity. The following figures show sections of some crystals. Fig. 5, by C. T. Jackson in J. Soc. N. Hist., Bost., 1, 55; figs. *a* and *b* are from opposite extremities of the same crystals; so also *c* and *d*; *e* and *f*.

5.

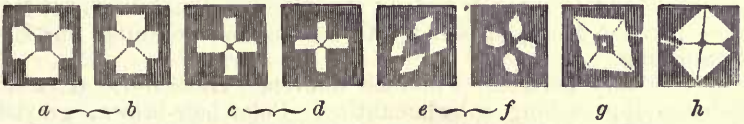


Fig. 6 shows the successive parts of a single crystal, as dissected by B. Horsford of Springfield, Mass. The forms of the white and black portions vary much. Bernhardi showed in 1807 (l. c.) that the central column sometimes widened *from the middle* toward each end.

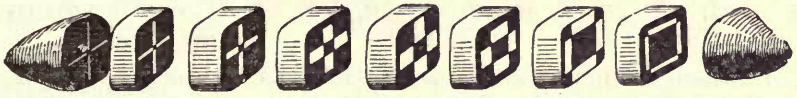
6.



**Comp.**—$Al_2SiO_5 = (AlO)AlSiO_4$ or $Al_2O_3.SiO_2$ = Silica 36·8, alumina 63·2 = 100.

A little iron is usually present; analyses see 5th Ed., p. 372. Damour obtained for the Brazilian mineral: $SiO_2$ 37·24, $Al_2O_3$ 62·07, $Fe_2O_3$ 0·61 = 99·92, Dx., Min., 1, 336, 1862.

**Pyr., etc.**—B.B. infusible. With cobalt solution gives a blue color after ignition. Not decomposed by acids. Decomposed on fusion with caustic alkalies and alkaline carbonates. See also sillimanite, p. 499.

**Obs.**—Most common in argillaceous schist, or other schists imperfectly crystalline; also in gneiss, mica schist, and related rocks; rarely in connection with serpentine. The variety chiastolite is commonly a contact mineral in clay-slates, *e.g.*, adjoining granitic dikes. Sometimes associated with sillimanite with parallel axes.

Found in Spain, in Andalusia; in the Tyrol, Lisens Alp, in large cryst. with cyanite; in Saxony, at Bräunsdorf, Robschütz, Munzig, Penig; in Moravia, at Goldenstein; Bavaria, at Wunsiedel, Lahmerwinkel. Rabenstein, etc.; Austria, at Felling, near Krems, in serpentine; France, Dept. of Var. near Hyères; Barèges in the Pyrenees; Russia, Yushakova near Mursinka in the Ural; Mankova, etc., in Nerchinsk (*chiastolite*). In Ireland at Killiney Bay, in mica schist; near Balahulish in Argyleshire; Cumberland, England. In Brazil, province of Minas Geraes. in fine crystals and as rolled pebbles.

In N. America, in *Maine*, at Mt. Abraham, Bangor, Searsmont, Camden, S. Berwick; also in fine pink crystals in quartz with pyrrhotite at Standish. *N. Hamp.*, at White Mtn. Notch; Boar's Head, near Rye; at Charleston. *Vermont*, near Bellows Falls. *Mass.*, at Westford, abundant in cryst., sometimes rose-colored; Lancaster, both varieties; Sterling, chiastolite. *Conn.*, at Litchfield and Washington, good cryst. *Penn.*, in Delaware Co., near Leiperville, large cryst.; at Marple, Upper Providence, and Springfield, good cryst.; one weighing 7½ lbs., and a group of crystals, free from the gangue, of about 60 lbs. *California*, along the Churchillas rivers, San Joaquin val., at crossing of road to Ft. Miller. In *Canada*, at L. St. Francis, in reddish cryst., in mica schist, both var. In *N. Scotia*, at Cape Canseau.

Named from Andalusia, the first locality noted.

The name *macle* is from the Latin *macula, a spot*, and, as Robien observes, it alludes to the use of the "*mascle*" in heraldry, in which the word signifies *a voided lozenge*, or a rhomb with open centre (l. c., 1751, in de Lisle, Crist.). Chiastolite is from χιάστος, *arranged diagonally*, and hence from *chi*, the Greek name for the letter X.

**Alt.**—Andalusite occurs altered to kaolin; sometimes to muscovite (and pinite); also to cyanite.

**Ref.**—[1] Min., p. 173, 1862. Haid. gave 89° 10′, Pogg., **61**, 295, 1844; Mlr. 89° 16′, Min., p. 284; Grünhut 89° 15′, Zs. Kr., **9**, 120, 1884. [2] Cf. Haid., Mlr., l. c., and Kenng., Ber. Ak. **399. SILLIMANITE** or FIBROLITE. Faserkiesel (fr. Bohemia) *Lindacker*, Mayer's Samml. phys. Aufs., **2**, 277, 1792; Bergm. J., **2**, 65, 1792. Fibrolite (fr. the Carnatic) *Bournon*, Phil. Trans., 289, 335, 1802; = Bournonite *Lucas*, Tabl., **2**, 216, 1813. Bucholzit (fr. Tyrol) *Brandes*, Schw. J., **25**, 125, 1819. Sillimanite (fr. Conn.) *Bowen*, Am. J. Sc., **8**, 113, 1824. Wörthite *Hess*, Pogg., **21**, 73, 1830. Xenolit *Nordensk.*, Act. Soc. Sc. Fenn., 1, 371, Pogg., **56**, 643, 1842. Bamlit *Erdmann*, Ak. H. Stockh., 19, 1842. Monrolite (fr. Monroe, N. Y.) *Silliman*, Am. J. Sc., **8**, 385, 1849.

Orthorhombic. Axes $\breve{a} : \bar{b} = 0{\cdot}970 : 1$. Forms: $a$ ($100$ $i$-$\bar{\imath}$), $b$ ($010$, $i$-$\breve{\imath}$), $m$ ($110$, $I$), $h$ ($230$, $i$-$\breve{\tfrac{3}{2}}$). Angles[1] $mm''' = 88° \ 15'$, $hh' = {}^*69°$. Prismatic faces striated and rounded. Commonly in long slender crystals not distinctly terminated; often in close parallel groups, passing into fibrous and columnar massive forms; sometimes radiating.

Cleavage: $b$ very perfect. Fracture uneven. H. = 6–7. G. = 3·23–3·24. Luster vitreous, approaching subadamantine. Color hair-brown, grayish brown, grayish white, grayish green, pale olive-green. Streak uncolored. Transparent to translucent.

Pleochroism sometimes distinct: $\mathfrak{c}$ dark clove-brown, $\mathfrak{b}$ light brownish, Rosenbusch. Optically +. Double refraction strong. Ax. pl. $\parallel b$. Bx $\perp c$. Dispersion $\rho > v$.

$$2E_r = 44° \qquad 2E_{gr} = 42°\text{–}43° \qquad 2E_v = 37°\text{–}38°. \qquad \beta_r = 1{\cdot}660, \text{ Dx.}$$
$$\alpha = 1{\cdot}659 \qquad \beta = 1{\cdot}661 \qquad \gamma = 1{\cdot}680, \text{ Lcx.}^2$$

**Var.**—1. *Sillimanite.* In long, slender crystals, passing into fibrous forms, with the fibers separable. G. = 3·238, Norwich, Ct., Dana; 3·232, id., Brush; 3·239, Yorktown, Norton.

Also densely compact, and in this form used for utensils and implements by prehistoric man in western Europe, and sometimes called "jade." See Damour (C. R., **61**, 318, 1865), who gives for a specimen from Haute Loire, with G. = 3·209: $SiO_2$ 37·18, $Al_2O_3$ 61·17, $Fe_2O_3$ 0·70, ign. 1·06 = 100·11. Also F. W. Clarke (Proc. U. S. Mus., **11**, 128, 1888), who gives for a specimen from Brittany, with G. = 3·147: $SiO_2$ 34·66, $Al_2O_3$ 63·24, $Fe_2O_3$ *tr.*, MgO 0·37, ign. 1·31 = 99·58. On Spanish fibrolite implements (jade), see Quiroga, abstr. in Zs. Kr., **6**, 270, 1881.

2. *Fibrolite.* Fibrous or fine columnar, firm and compact, sometimes radiated; grayish white to pale brown, and pale olive-green or greenish gray. *Bucholzite* and *monrolite* are here included; the latter is radiated columnar, and of the greenish color mentioned. G. = 3·24, fibrolite, Bournon; 3·19–3·21, id., Dmr.; 3·239, bucholzite, Chester, Pa., Erdmann; 3·04–3·1, monrolite, B. Silliman; 3·075, id., Brush.

*Bamlite*, from Bamle, Norway, resembles the monrolite, being columnar subplumose, silky; G. = 2·984, and color greenish white or bluish-green. The analysis of Erdmann gave a large excess of silica (56·90 p. c.); but L. Sæmann observes that there are minute prisms of quartz among the fibers of bamlite. A bamlite from the gneiss of Larangeiras, Brazil, with G. = 3·18, gave Dom Pedro Augusto von Sachsen-Coburg: $SiO_2$ 57·50, $Al_2O_3$ 41·50 = 99·00; this is probably also impure from the presence of quartz, Min. Mitth., **10**, 460, 1889.

*Xenolite* also resembles fibrolite closely, excepting in the high specific gravity, 3·58, which suggests an identity rather with cyanite. But the prisms are stated to have the angle 89°, which is the angle of andalusite; and Des Cloizeaux states that it is optically like fibrolite, and not like cyanite. In rolled pebbles from Peterhof, Finland, and near St. Petersburg. Named from ξένος, *stranger*. Komonen (l. c.) obtained: $SiO_2$ 47·44, $Al_2O_3$ 52·54 = 99·98.

*Wörthite* is hydrous, and is probably a somewhat altered and impure form. H. = 7·25, color white, translucent. Optically like the above. An analysis gave Hess (l. c.): $SiO_2$ 40·58, $Al_2O_3$ 53·50, MgO 1·00, $H_2O$ 4·63 = 99·71. From Peterhof with xenolite. Cf. Fischer, Vh. Ges. Freiburg, **5**, 29; Lcx.², l. c., p. 154. Named for Von Wörth, a secretary of the Russian Mineralogical Society.

**Comp.**—$Al_2SiO_5$ or $Al_2O_3.SiO_2$ = Silica 36·8, alumina 63·2 = 100; the rational formula probably $(AlO)AlSiO_4$ like andalusite (Groth).

Analyses (5th Ed., p. 374 and above) in general agree closely, but Wiik gives (Zs. Kr., **2**, 496, 1878) for sillimanite from St. Michel: $SiO_2$ 47·33 $Al_2O_3(Fe_2O_3$ *tr*) 52·21 = 99·54, yielding the orthosilicate formula $Al_4(SiO_4)_3$, like xenolite above; cf. also anal. 5, 6, 5th Ed., p. 374.

**Obs.**—Occurs in gneiss, mica schist, and related crystalline rocks, usually in slender prisms aggregated in lines, sometimes associated in parallel position with andalusite (Lcx.²); iolite is also a common associate; rarely as a contact mineral.

Observed in many localities, thus near Moldau and Schüttenhofen in Bohemia (*faserkiesel*); at Fassa in Tyrol (*bucholzite*); in the Carnatic with corundum (*fibrolite*); at Bodenmais in Bavaria; Tillenberg near Eger in Bohemia; Marschendorf in Moravia; Freiberg, Saxony; in France, in the vicinity of Issoire in boulders, and also in the canton of Paulhaguet; near Pontgibaud and other points in Auvergne; in the Dept. Basse-Loire near Nantes and elsewhere. In gneiss in Aberdeenshire, Scotland; Sievenberg, Heteroland, South Africa. Greenish gray sillimanite in quartz-forms rolled masses in the diamantiferous sands of Diamantina, Minas Geraes, Brazil.

In the United States, in *Massachusetts*, at Worcester. In *Connecticut*, at the falls of the Yantic, near Norwich, with zircon, monazite, and corundum; at Willimantic; at Chester, near Saybrook (*sillimanite*); at Humphreysville. In *N. York*, at Yorktown, Westchester Co., 10 m. N.E. of Sing Sing; near the road leading from Pine's Bridge to Yorktown P. Office, in distinct crystals, with monazite, tremolite, and magnetite, the crystals often running through the magnetite; in Monroe, Orange Co. (*monrolite*), with mica, garnet, magnetite, etc. In *Penn.*, at Chester on the Delaware, near Queensbury forge; in Delaware Co., in Birmingham, Middletown, Concord, Aston, Darby; sometimes, as at Mineral Hill, associated with corundum and derived from its alteration (Genth). In *Delaware*, at Brandywine Springs. With corundum at the Culsagee mine, Macon Co., *N. Carolina*, and from Laurens, *S. Carolina*.

Named *fibrolite* from the fibrous massive variety (*Germ.*, Faserkiesel); *bucholzite*, after the German chemist Bucholz; *sillimanite*, after Prof. Benjamin Silliman of New Haven (1779–1864).

**Artif.**—A compound near sillimanite was early (1858) formed by St. Claire Deville and Caron by reaction at a high temperature of silica on aluminium fluoride, or of aluminium on silicon fluoride. Similar results have been obtained by Frémy and Feil (1877) and later more definitely by Vernadsky, who further shows that cyanite is transformed at 1320°–1380° into sillimanite, and the same is true of andalusite, both with the disengagement of heat. A similar transformation seems to take place in the case of dumortierite and topaz. See Bull. Soc. Min., **12**, 447, 1889, **13**, 256, 1890, also further under cyanite.

**Ref.**—¹ Dx., Min., **1**, 178, 1862; Bull. Soc. Min., **4**, 258, 1881. ² Lcx., Bull. Soc. Min., **11**, 150, 1888. The position here taken brings sillimanite into relation with andalusite; with Dx. the 69° prism is taken as the unit.

GLANCESPAR. Glanzspath *von Dechen*, Geogn. Führer Siebengebirge, 154, 1861; Rath, Pogg., **147**, 272, 1872.

Occurs in small prismatic fragments in the basalt of the Siebengebirge. Form a rhombic prism having an acute angle of 88½°. Cleavage pinacoidal distinct, with pearly luster. H. = 6·5. G. = 3·150. Analysis.—Rath:

$SiO_2$ 36·7 $Al_2O_3$ 57·9 $Fe_2O_3$ 4·4 MgO 0·7 CaO 0·8 = 100·5

Composition deducting impurities like sillimanite. Cf. Vernadsky, Bull. Soc. Min., **12**, 455, 1889.

WESTANITE *C. W. Blomstrand*, Öfv. Ak. Stockh., **25**, 208, 1868.

In radiated crystalline masses, sometimes in prismatic crystals. H. = 2·5. Color brick red. An analysis gave:

$SiO_2$ [42·53] $Al_2O_3$ 51·14 $P_2O_5$ 1·15 $Fe_2O_3$ 1·01 $H_2O$ 4·17 = 100

This composition is near wörthite, a hydrous fibrolite, but it differs from that mineral in inferior hardness. It may be an altered andalusite as suggested by Groth (Tab. Ueb., 106, 1889). B.B. swells up; infusible and turns white. Not acted upon by acids. Associated with pyrophyllite at Westanå, Sweden.

**400. CYANITE.** Talc bleu *Sage*, Descr. Cab. de l'École des Mines, 154, 1784. Sappare *Saussure fils*, J. Phys., 34, 213, 1789. Beril feuilleté *Sage*, J. Phys., 31, 39, 1789. Cyanit (fr. Greiner) *Wern.*, Hoffm., Bergm. J., 377, 393, 1789; *Wern.*, ib., 164, 1790; Kyanite. Disthène *H.*, Tr., 3, 101. Rhætizit (fr. Pfitschthal, or ancient Rhætia) *Wern.*, Hoffm. Min., 2, b, 318, 1815, 4, b, 128, 1817.

Triclinic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·89938 : 1 : 0·70896$; $\alpha = 90° 5\frac{1}{2}'$, $\beta = 101° 2\frac{1}{4}'$, $\gamma = 105° 44\frac{1}{2}'$ Rath[1].

$100 \wedge 010 = 73° 56'$, $100 \wedge 001 = {}^{*}78° 30'$, $010 \wedge 001 = 86° 45'$.

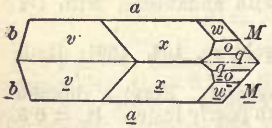
Twins: tw. ax. (1) a normal to *a*, comp.-face *a*, often polysynthetic; (2) the normal to the edge *a*/*b* in *a*; (3) the edge *a*/*c*; (4) a normal to *c*, as penetration-twins, often repeated and as a result of pressure; also staurolite-like cruciform-twins crossing at 60°. Usually in long bladed crystals, rarely terminated. Face *a* often striated ‖ edge *a*/*c* (f. 3). Also coarsely bladed columnar to subfibrous.

4.



Cleavage: *a* very perfect; *b* less perfect; also parting ‖ *c* which is a gliding-plane, parallel to which twinning is produced by pressure[2]. H. = 5–7·25; the least, 4–5, on *a* ‖ $\dot{c}$; 6–7 on *a* ‖ edge *a*/*c*; 7 on *b*. G. = 3·56–3·67; 3·559, white; 3·675, blue; 3·661, Tyrol, Erdmann. Luster vitreous to pearly. Color blue, white; blue along the center of the blades or crystals with white margins; also gray, green, black. Streak uncolored. Translucent to transparent.

Pleochroism distinct in colored varieties. Optically −. Ax. pl. nearly ⊥ *a* and inclined to edge *a*/*b* on *a* about 30° (f. 3), and about 7½ on *b*. Axial angle large, 2V = 82°–83°. Index $\beta_r = 1·720$ Dx.[3] Also Korn[3]:

Pfitschthal $2\mathrm{H}_{a.r} = 99° 18'$ Li $2\mathrm{H}_{a.y} = 98° 55'$ Litchfield $2\mathrm{H}_{a.r} = 100° 50\frac{1}{2}'$ $2\mathrm{H}_{a.y} = 100° 41\frac{1}{2}'$

Comp.—Empirical formula $Al_2SiO_5$ or $Al_2O_3.SiO_2$, like andalusite and sillimanite. Perhaps (Groth) a basic metasilicate $(AlO)_2SiO_3$.

Analyses, 5th Ed., p. 376. A pale green variety from Clip, Arizona, associated with dumortierite, gave Hillebrand (priv. contr.): G. = 3·656, $SiO_2$ 36·30, $Al_2O_3(TiO_2)$ 62·51, $Fe_2O_3$ 0·70, CuO *tr.*, ign. 0·40 = 99·91.

**Pyr., etc.**—Same as for andalusite.

At a high temperature (1320°–1380°) cyanite is transformed into sillimanite; the hardness becomes uniformly 6–7 instead of 5 to 7; the specific gravity falls to 3·15–3·23; the extinction becomes parallel and the optical character +. Cf. Vernadsky, Bull. Soc. Min., **12**, 447, 1889, **13**, 256, 1890.

**Obs.**—Occurs principally in gneiss and mica schist (both the ordinary variety with muscovite and also that with paragonite) often accompanied by garnet and sometimes by staurolite; also in eclogyte. It is often associated with corundum.

Found in transparent crystals at Monte Campione in the St. Gothard region in Switzerland in paragonite schist; on Mt. Greiner, Zillerthal, and in the Pfitschthal (*rhætizite*, a white variety) in Tyrol; also near Admont in Styria; in eclogyte of the Saualpe, Carinthia; Petschau, Bohemia; Heräjoki, Finland; Horrsjöberg in Wermland, Sweden, forming beds enclosing damourite, in quartzyte; on the R. Sanarka, Gov't Orenburg, Russia, in the gold-washings, accompanying euclase and topaz; at Pontivy, France; Villa Rica, Brazil, S. America; in Scotland, at Botriphinie in Banffshire, at Banchory in Aberdeenshire, and near Glen Tilt; in the Shetlands at Hillswickness; in Ireland, at Donegal and Mayo.

In *N. Hamp.*, at Jaffrey, on the Monadnock Mtn. In *Mass.*, at Chesterfield, with garnet in mica schist; at Worthington and Blanford in good specimens; at Westfield and Lancaster. In *Conn.*, at Litchfield and Washington in large rolled masses, with corundum and massive apatite; at Oxford, near Humphreysville, in mica schist. In *Vermont*, at Thetford and Salisbury; at Bellows Falls in short disseminated crystals. In *Penn.*, in fine specimens near Philadelphia, on the Schuylkill road near the Darby bridge; near the Schuylkill, on the Ridge road, back of Robin Hood tavern; at East and West Branford, Chester Co.; at Darby and Haverford, Delaware Co. In *Maryland*, eighteen miles north of Baltimore, at Scott's mill; in *Delaware* near Wilmington. In *Virginia*, at Willis's Mt., Buckingham Co., and two miles north of Chancellorville, Spotsylvania Co. In *N. Carolina*, with rutile, lazulite, etc., at Crowder's Mt., Gaston Co., sometimes black; of fine deep blue color near Bakersville near the summit of Yellow Mt. on the road to Marion Co. (Kunz). In Gaston and Rutherford counties associated with corundum, damourite; also at Swannanoa Gap, Buncombe Co., and elsewhere: in these and similar cases according to Genth derived from the corundum. In British Columbia on the North Thompson River in quartz.

Named from κυανός, *blue.* The name *sappare* arose from a mistake by Saussure, Jr., in reading a label of this mineral on which it was called sapphire; a copy of this label is given in J. Phys., **34**, 213; the specimen thus labelled was from Botriphinie in Scotland, and was sent by the Duke of Gordon to Saussure the father. *Disthene* is from δίς, *twice*, or of two kinds, and σθένος, *strong*, alluding to the unequal hardness and electric properties in two different directions.

**Alt.**—Cyanite occurs altered to talc and steatite.

An analysis of an alteration product from Pregratten gave Böhm, Min. Mitth., **2**, 522, 1880:

| $SiO_2$ | $Al_2O_3$ | FeO | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 36·62 | 46·39 | 0·90 | 7·35 | 0·58 | 1·93 | 2·75 | 4·51 | = 101·03 |

## 12. Datolite Group. Monoclinic.

Basic Orthosilicates. $H\overset{II}{R}\overset{III}{R}SiO_5$ or $\overset{II}{R}_3\overset{III}{R}_2(SiO_5)_2$. Oxygen ratio for R : Si = 3 : 2.
$\overset{II}{R}$ = Ca,Be,Fe, chiefly; $\overset{III}{R}$ = Boron, the yttrium (and cerium) metals, etc.

| | | $\grave{a} : \acute{b} : c$ | $\beta$ |
|---|---|---|---|
| 401. | **Datolite**<br>$HCaBSiO_5$ or $Ca(BOH)SiO_4$ | 0·6345 : 1 : 1·2657 | 89° 51′ |
| 402. | **Homilite**<br>$Ca_2FeB_2Si_2O_{10}$ or $Ca_2Fe(BO)_2(SiO_4)_2$ | 0·6249 : 1 : 1·2824 | 89° 21′ |

$2\grave{a} : \bar{b} : 4\grave{c}$ $\beta$

**403. Euclase** $0{\cdot}6474 : 1 : 1{\cdot}3330$ 79° 44′

$HBeAlSiO_5$ or $Be(AlOH)SiO_4$

$\grave{a}$

**404. Gadolinite** $0{\cdot}6273 : 1 : 1{\cdot}3215$ 89° 26½′

$Be_2FeY_2Si_2O_{10}$ or $Be_2Fe(YO)_2(SiO_4)_2$

---

**405. Yttrialite** $Y_2O_3,ThO_2$, etc., $SiO_2$ Massive

Silicate of thorium, yttrium earths, etc. Oxygen ratio for Si : R = 4 : 3.

The formulas of the species of the Datolite Group are written as basic orthosilicates in the form suggested by Groth. The crystallographic and chemical relation between datolite and euclase was shown by J. D. Dana in 1854 (Am. J. Sc., **17**, 215, 1854, **49**, 400, 1870, and Min., 4th Ed., p. 204, 5th Ed., pp. 362, 363) and later by Rammelsberg (Zs. G. Ges., **21**, 807, 1869), who also proved the isomorphism of datolite and gadolinite. The latter author shows that the axial ratio and obliquity of euclase may be made to correspond to them, and he calculates: $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}6303 : 1 : 0{\cdot}6318$, $\beta = 88°\ 18'$. The complex character of the symbols resulting from this change shows, however, that the position is an unnatural one.

Yttrialite, associated with the Gadolinite of Texas and like it chiefly a silicate of the rare metals of the yttrium group, is conveniently introduced here, although a more highly acid compound and hence of different formula.

---

**401. DATOLITE.** Datolith (fr. Arendal) *Esmark* (undescr.); *Karsten & Klapr.*, Gehlen's J., **6**, 1806, Klapr. Beitr., **4**, 354, 1807; *Karst.*, Tab., 52, 1808. Datholit *Wern.*, 1808. Crystals varied in habit; usually short prismatic with either $m$ or $m_x$ predominating; also of other types, and often highly modified. Faces often wavy and rarely giving good measurements; $x$ (102) commonly dull. Also botryoidal and globular, having a columnar structure; divergent and radiating; sometimes massive, granular to compact and cryptocrystalline.

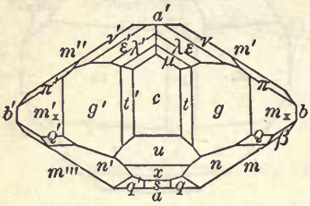
10.



Bergen Hill.

Cleavage not observed. Fracture conchoidal to uneven. Brittle. H. = 5–5·5. G. = 2·9–3·0. Luster vitreous, rarely subresinous on a surface of fracture. Color white; sometimes grayish, pale green, yellow, red, or amethystine, rarely dirty olive-green or honey-yellow. Streak white. Transparent to translucent; rarely opaque white.

Optically −. Ax. pl. ‖ $b$. $\mathfrak{a}$ (= $Bx_a$) nearly ⊥ $a$. $Bx_o \wedge \grave{c} = +1°$ Na, $Bx_a \wedge \grave{c} = -89°$ S. d. Zanchetti; $Bx_{o.y} \wedge \grave{c} = +2° 27'$ Na, Bergen Hill. Refractive indices, etc., Brugnatelli[3]:

For Li $\alpha_r = 1{\cdot}6214$ $\beta_r = 1{\cdot}6492$ $\gamma_r = 1{\cdot}6659$ $\therefore$ $2V_r = 74° 26'$
Na $\alpha_y = 1{\cdot}6246$ $\beta_y = 1{\cdot}6527$ $\gamma_y = 1{\cdot}6694$ $\therefore$ $2V_y = 74° 8'$

Also measured, where $n_r = 1{\cdot}6474$, $n_y = 1{\cdot}6576$:
$2H_{a.r} = 74° 44'$ Li $2H_{a.y} = 74° 6'$ Na $2H_{a.gr} = 73° 27'$ Tl $\therefore$ $2V_y = 74° 21'$

Luedecke obtained for Andreasberg:
$Bx_o \wedge \grave{c} = +3° 6'$ Li 3° 8′ Na 3° 12′ Tl; also
$2H_{a.y} = 79° 26'$ $2H_{o.y} = 114° 55'$ $\therefore$ $2V_y = 74° 19'$ and $\beta_y = 1{\cdot}6494$.

**Var.**—1. *Ordinary.* In glassy crystals of varied habit, usually with a greenish tinge. The angles in the prismatic and clinodome zones vary but little, e.g., 110 ∧ $\bar{1}10$ = 64° 47′, while 011 ∧ $01\bar{1}$ = 66° 37′, etc. Hence the position here taken exhibits the crystallographic relation to the following species as well as that of Rammelsberg and Groth, and the optical relations better, since in datolite (optically −), homilite (+), and gadolinite (+) the axis $\mathfrak{c}$ is nearly ‖ $\grave{c}$. Moreover, it is shown to be more natural by the habit of the crystals and the symbols of the chief forms. This similarity in the angles of zones named makes it easy to blunder in the orientation of crystals; several authors have added "new forms" based upon such an error.

2. *Compact massive.* White opaque cream-colored, pink; breaking with the surface of porcelain or Wedgewood ware. G. = 2·911, Hayes; 2·983, Chandler. From the L. Superior region (anal. 12)

3. *Botryoidal; Botryolite.* Radiated columnar, having a botryoidal surface, and containing more water than the crystals, but optically identical, Lcx., Bull., 8, 434, 1885. The original locality of both the crystallized and botryoidal was Arendal, Norway.

**Comp.**—A basic orthosilicate of boron and calcium; empirically $HCaBSiO_5$ or $H_2O.2CaO.B_2O_3.2SiO_2$; this may be written (Groth) $Ca(BOH)SiO_4$ = Silica 37·6, boron trioxide 21·8, lime 35·0, water 5·6 = 100.

**Anal.**—1, 2, Rg., Pogg., **47**, 175, 1839. 3, Lemberg, Zs. G. Ges., **24**, 250, 1872. 4, Preis, ib., **4**, 360, 1880 (after deducting 3·5 $CaCO_3$). 5, Bechi, quoted by Issel, Boll. Com. **Pyr., etc.**—In the closed tube gives off much water. B.B. fuses at 2 with intumescence to a clear glass, coloring the flame bright green. Gelatinizes with hydrochloric acid.

**Obs.**—Datolite is found chiefly as a secondary mineral in veins and cavities in basic eruptive rocks, often associated with calcite, prehnite, and various zeolites; sometimes associated with danburite; also in gneiss, dioryte, and serpentine; in metallic veins; sometimes also in beds of iron ore.

Found in Scotland, in trap, at the Kilpatrick Hills, Glen Farg in Perthshire, and in Salisbury Craigs; in a bed of magnetite at Arendal in Norway, and Utö in Sweden; at Andreasberg in diabase and in veins of silver-ores; at Niederkirchen and Sonthofen in Rhenish Bavaria (the *humboldtite*); at the Seisser Alp, Tyrol, and also at Theiss, near Claussen, in geodes in amygdaloid; in dioryte on the Rosskopf, near Freiburg in Baden; at Kuchelbad near Prague in Bohemia; Schneidemüllerskopf in the Ilmthal, Thuringia; Markirch in Alsace; in granite at Baveno near Lago Maggiore; at Toggiana in Modena, in serpentine; in highly complex crystals in the contact zone between the euphotide and the serpentine of the Serra dei Zanchetti; Fossa della Castellina near Porretta; Casarza in Liguria; Monte Catini in Tuscany, in chalcopyrite, also in cavities and veins in a red gabbro.

In the U. S. not uncommon with the diabase of Connecticut and Massachusetts. Thus at the Rocky Hill quarry, Hartford, Conn.; in the northeast part of Southington, in amygdaloid; also in Berlin, near Kensington; filling small cavities in amygdaloid at Meriden, usually of a deep yellow green, also in crystals; at Middlefield Falls, Conn.; in fine specimens at Roaring Brook, 14 miles from New Haven; at Tariffville in large crystals; Deerfield, Mass. Rare with diopside at De Kalb in St. Lawrence Co., New York; also with the danburite of Russell, but rare. In N. Jersey, at Bergen Hill, in splendid crystals; at Paterson, Passaic Co. In trappean rocks, both crystals and the opaque compact variety, in the Lake Superior region, at the Minnesota, Quincy, Marquette, Ash-bed, and other mines; at the Superior mine near Ontonagon and on Isle Royale. With grossular garnet, vesuvianite at San Carlos, Inyo Co., Cal.

Named from δατεῖσθαι, *to divide*, alluding to the granular structure of a massive variety. Werner introduced an *h* after the first *t* without reason, and most subsequent authors have followed him in this; but not Karsten, nor Leonhard who pronounced it wrong, nor Haidinger, Aikin, Jameson, and others.

Lévy gave the name *humboldtite* to crystals which he found to be *monoclinic*, datolite having been made orthorhombic by Haüy. Wollaston proved their identity with datolite.

**Alt.**—Haytorite is datolite altered to chalcedony, from the Haytor iron-mines in Devonshire, England.

**Ref.**—[1] Andreasberg-Toggiana, Pogg., **103**, 116, 1858; cf. Schröder, ibid., **94**, 235, 1855, **98**, 34, 1856; also Luedecke, Ueber Datolith, Halle, 1889. The form was early regarded as orthorhombic and hemihedral. Some authors make $m_x$ the unit prism, following Dbr., or *g* with Rg., and Groth, but the above position gives the simplest symbols, and also exhibits well the relation to the other species of the group; here $\grave{c} = 4\grave{c}$ Dana, 1868, 1872–4.

[2] Cf. Mlr., Min. 408, 1852; Sdr., l. c.; Dbr., l. c.; Dx., Min., **1**, 167, 1862; E. S. D., Min. Mitth., 1, 1874; Gdt., Index, **1**, 485, 1886, and Luedecke, l. c. Luedecke reviews with great minuteness the results of earlier observers, and adds many original observations with new forms, measurements of angles, and optical constants, etc., based upon the study of crystals from many localities; note, however, the criticism of Gdt. (Zs. Kr., **18**, 280, 1890), who shows that 17 of Luedecke's 30 new forms were probably determined on crystals of anglesite, and are hence to be rejected. The other 13 planes (not all above question, Gdt.) added by Luedecke are as follows: 8·11·0; 504; 0·13·18, 041; 421, 544, 763, 10·9·9; $\bar{1}\bar{0}$·7·14; 148; $\bar{1}$27, $\bar{1}$·2·15, $\bar{1}$32.

The literature of the subject includes the following leading articles: Schröder, Dauber, and other authors already referred to; also E. S. D., Bergen Hill, Am. J. Sc., **4**, 16, 1872; Toggiana, Andreasberg, etc., Min. Mitth., 1, 1874; Bombicci, Fosse della Castellina, Mem. Acc. Bologna, **8**, 311, 1877; also Serra dei Zanchetti, ib., **7**, 100, 1886; Vrba, Kuchelbad, Zs. Kr., **4**, 358, 1880, Theiss, **5**, 425, 1881; Lehmann, Niederkirchen, Zs. Kr., **5**, 529, 1881; Brugnatelli, Serra dei Zanchetti, Zs. Kr., **13**, 150, 1887; Negri, Casarza, Riv. Min., **1**, 45, 1887; Sansoni, Monte Catini, Att. Acc. Torino, **23**, 198, 1888; Franzenau, Seisser Alp, Zs. Kr., **14**, 390, 1889; Luedecke, l. c.

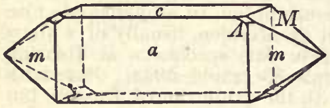

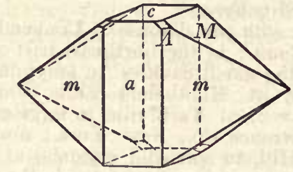

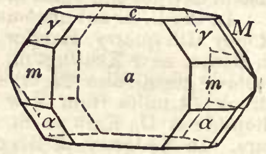

Figs. 1–6, Norway, Bgr.

Twins: tw. pl. (1) *c*, contact-twins with *c* as comp.-face; (2) *a*, similar, but with *a* as comp.-face; these two kinds of twins give nearly the same angles, so that in some cases the second kind could be explained as being twins with *c* as tw. pl. and *a* as comp.-face. Also (3) *g* (034) cruciform-twins with the vertical axes nearly at right angles, since *cc* = 87° 46′. (4) σ (021) somewhat uncertain, observed only on a single specimen where the association may have been accidental. Crystals often tabular ‖ *c*; also with *a* prominent; or octahedral in habit by development of *m* and *M* (012), or *m* and α ($\bar{1}11$).

Cleavage indistinct. Fracture subconchoidal. Brittle. H. = 5. G. = 3·38 Nobel; 3·34 Dmr. Luster resinous to vitreous. Color black, blackish brown. Streak grayish. Opaque or translucent only in thin splinters. Pleochroism distinct: $\mathfrak{c}$ (= $\acute{c}$) deep smoky gray or brownish yellow, $\mathfrak{b}$ (= $\grave{a}$) deep brownish red, $\mathfrak{a}$ (= $\bar{b}$) bluish green. Absorption, $\mathfrak{b} > \mathfrak{a} > \mathfrak{c}$. Optically +. Ax. pl. ⊥ *b*. $\mathfrak{a}$ (= $Bx_o$) nearly ⊥ *a* like datolite; $Bx_a$ almost ‖ $\acute{c}$. Dispersion horizontal, distinct. Also isotropic and amorphous by alteration.

$2H_{a.r}$ = 97° 5′ to 98° 22′, Dx.
$2H_{a.r}$ = 93° 8′ $2H_{o.r}$ = 125° 33′ ∴ $2V_r$ = 79° 59′ $2H_{a.bl}$ = 91° 12′ Bgr.

Des Cloizeaux shows that some crystals of homilite are throughout doubly refracting, others are composed of a green doubly refracting kernel surrounded by a yellowish crust of singly refracting material, while still others are entirely isotropic. Brögger describes a zonal structure in the crystals with varying position of the bisectrix, a few degrees (+ or −) on either side of the axis $\acute{c}$; moreover, sections ‖ *c* show a division into fields of hour-glass form. The zonal structure is in part original, in part a consequence of incipient alteration, which last also explains the variation in the position of the bisectrix, which takes place most rapidly in a direction ‖ *c*. The final result of the alteration is the amorphous material before noted. It is to be noted that the change from a crystalline anisotropic to the amorphous isotropic condition is common in certain of the minerals of the "Brevik" region in Norway (also elsewhere); cf. gadolinite, allanite, etc.

**Comp.**—$(Ca,Fe)_3B_2Si_2O_{10}$ or $(Ca,Fe)_3(BO)_2(SiO_4)_2$. If Ca : Fe = 2 : 1, this is equivalent to $2CaO.FeO.B_2O_3.2SiO_2$ = Silica 32·1, boron trioxide 18·7, iron protoxide 19·3, lime 29·9 = 100.

**Anal.**—1, Paijkull, l. c. 2, Damour, l. c. 3, G. V. Petersson, Öfv. Ak Stockh., **45**, 185, 1888.

[a] Incl. $K_2O$ 0·41. [b] With MnO 0·74.

**Pyr., etc.**—B.B. homilite fuses very readily to a black glass; reacts for iron and boric acid. Completely decomposed by hydrochloric acid with gelatinization.

**Obs.**—Found on the island Stokö and the neighboring islands, Store-Arö and Övre-Arö in the Langesund fiord, Norway, in veins in augite-syenite, with meliphanite and erdmannite; also titanite, zircon, ægirite, löllingite; further, as accessory associated ~~species,~~ astrophyllite, melanocerite, nordenskiöldine, wöhlerite, hiortdahlite, molybdenite, etc. The largest well developed crystal of homilite found had a length of about 2 inches in the direction of the orthodiagonal axis; another imperfect crystal had a weight of 50 grams. Named from *ὁμιλεῖν, to occur together*, in allusion to its association with meliphanite and erdmannite.

**Alt.**—As noted above, changes to an isotropic and amorphous material, analogous to gadolinite, allanite, etc. See also erdmannite below.

**Ref.**—[1] Ann. Ch. Phys , **12**, 405, 1877, and G. För. Förh., **3**, 385, 1877. Brögger, on the basis of numerous measurements, has calculated the axial ratio: $\grave{a} : \bar{b} : \dot{c} = 0{\cdot}62426 : 1 : 1{\cdot}30126$, $\beta = 89° \ 50'$, for which, however, he does not claim great accuracy. He proposes to accept the following: $a : b : c = 0{\cdot}6245 : 1 : 1{\cdot}2835$, $\beta = 89° \ 38'$, Zs. Kr., **16**, 134, 1890.

[2] Dx., l. c. [3] Bgr., G. För. Förh., **9**, 247, 1887, and l. c.

Brögger argues that the negative side of the homilite crystals may properly correspond to the positive side of gadolinite—in other words, the angle $\beta = 89° \ 21'$ of homilite may correspond to $90° \ 33\frac{1}{2}'$ of gadolinite, and he finds confirmation for this view in the position of the acute bisectrix. Brögger also calls attention to an apparent relation in form, as inferred by him, between homilite and zircon.

ERDMANNITE *Esmark. Berlin*, Pogg., **88**, 162, 1853. Michaelsonite *Dana*, Min. p. 289, 1868. A name originally given to a mineral supposed to be allied to allanite occurring in the "Brevik region" in southern Norway.

As described by Berlin, it occurred on the island Stokö in granular or lamellar masses, embedded in feldspar, not in distinct crystals. G. = 3·01. Luster vitreous. Color dark brown. Translucent in thin splinters. The following incomplete analysis was made by Blomstrand. (This was quoted in 5th Ed., p. 414, as an independent species, and again on p. 288 as a variety of allanite.)

| $SiO_2$ | $Al_2O_3$ | Ce-oxides | $Y_2O_3$ | FeO | MnO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 31·85 | 11·71 | 34·89 | 1·43 | 8·52 | 0·86 | 6·46 | [4·28] = 100 |

An analysis was later (1862) made by Michaelson (also another incomplete by Nobel, ibid.), Öfv. Ak. Stockh., **19**, 512, 1862. The mineral was from Arö, and was supposed to be the same as that investigated by Berlin, and was also referred to allanite. H. = 4·5. G. = 3·44. Michaelson's analysis is as follows:

| $SiO_2$ | $ZrO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Y_2O_3$ | $Ce_2O_3$ | $(La,Di)_2O_3$ | BeO | MgO | CaO | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 29·21 | 5·44 | 2·81 | 6·42 | 1·63 | 9·79 | 15·60 | 4·27 | 0·45 | 14·93 | 2·45 | 5·50 = 98·50 |

Brögger concludes after a study of this, the typical erdmannite, that although a resemblance to allanite is at first noted, this is apparent only, and that the material analyzed, which microscopic examination proves to be heterogenous, consists of a mineral of the melanocerite group (p. 413) appearing in the sections brown and isotropic, intermixed with a doubly refracting mineral, which is probably homilite or a closely allied species.

Also, besides this, there is another mineral, which has been called erdmannite, analyzed by Engström and Damour, below, which is probably a somewhat altered form of a kind of homilite peculiar in containing a considerable amount of the cerium metals, and for which, consequently, Brögger uses the name *Cerhomilite*.

Engstrom's mineral was leek-green in color, with G. = 3·388. Damour's was brown, with H. = 4·5, G. = 3·03. Optically isotropic, amorphous.

Anal.—1, Engström, Inaug. Diss., Upsala, p. 28, 1877. 2, Damour, Ann. Ch. Phys., **12**, 411, 1877.

| | $SiO_2$ | $ZrO_2$ | $ThO_2$ | $B_2O_3$ | $Fe_2O_3$ | $Ce_2O_3$ | $(Di,La)_2O_3$ | $Y_2O_3$ | $Er_2O_3$ | FeO | CaO | BeO | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 25·15 | 2·14 | 9·93 | 8·18 | 3·01 | 9·00 | 8·66 | 1·64 | 0·50 | 3·16 | 18·78 | 3·16 | 1·44[d] | 5·25 = 100 |
| 2. | 28·01 | 3·47 | 0·45[a] | [5·54] | 3·31[b] | 19·28 | 8·09 | — | — | 6·77[c] | 11·00 | — | 1·98 | 12·10 = 100 |

[a] $SnO_2$. [b] $Al_2O_3$. [c] Incl. 1·35 MnO [d] Incl. 1·02 $Na_2O$.

Engström calculates the formula $R_2O_3.SiO_2 + 3RO.SiO_2 + 1\frac{1}{2}H_2O$ and remarks upon its similarity in formula to datolite and gadolinite, a conclusion to which Brögger also arrives in a somewhat different way.

Brögger mentions also that much so-called erdmannite is only zircon usually much altered; cf. Zs. Kr., **16**, 109, 1890, also Krantz, Pogg., **82**, 586, 1851.

**403. EUCLASE.** *Haüy; Delameth.*, J. Phys., **41**, 155, 1792 (without credit to Haüy); T. T., **2**, 254, 1797 (with credit to Haüy); *Haüy*, J. Mines, **5**, 258, 1799, Tr., **2**, 1801. Euklas *Germ.*

Monoclinic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}32369 : 1 : 0{\cdot}33324$; $\beta = 79° \, 44' \, 4'' = 001 \wedge 100$ Schabus[1].

Only in crystals; habit prismatic with faces in zone *ab* vertically striated, and yielding an almost indefinite series of forms (see above).

Cleavage: *b* highly perfect; *a*, *c* rather difficult. Fracture conchoidal. Brittle. H. = 7·5. G. = 3·103 Kk.; 3·051, Sanárka, Erem; 3·089, 3·097 Brazil, Dx. Luster vitreous, somewhat pearly on the cleavage-face. Colorless, pale mountain-green, passing into blue and white. Streak uncolored. Transparent; occasionally subtransparent. Pleochroism distinct.

Optically +. Ax. pl. ∥ *b*. Bx nearly ∥ *P*, Dx. $Bx_a \wedge \dot{c} = +42° \, 16'$ Becke. Indices, Dx.

For Na $\alpha_y=1{\cdot}6520$ $\beta_y=1{\cdot}6553$ $\gamma_y=1{\cdot}6710$ $\therefore$ $2V_y=49°\ 37'$ $2E_y=87°\ 59'$
Measured $2E_r = 88°\ 47'$ $2E_{bl} = 88°\ 7'$ At 176° 2E increased 2° 18′

Electrified by friction.

**Comp.**—$HBeAlSiO_5 = Be(AlOH)SiO_4$ or $H_2O.2BeO.Al_2O_3.2SiO_2$ = Silica 41·3, alumina 35·2, glucina 17·3, water 6·2 = 100.

**Anal.**—Damour, C. R., **40**, 942, 1855. Also Berzelius, Mallet, 5th Ed., p. 380.

| | $SiO_2$ | $Al_2O_3$ | BeO | $H_2O$ | $Fe_2O_3$ | CaO | $SnO_2$ | F | |
|---|---|---|---|---|---|---|---|---|---|
| Brazil | ¼ 41·63 | 34·07 | 16·97 | 6·04 | 1·03 | 0·14 | 0·34 | 0·38 | = 100·60 |

**Pyr., etc.**—In the closed tube, when strongly ignited, gives off water. B.B. in the forceps cracks and whitens, throws out points, and fuses at 5·5 to a white enamel. Not acted upon by acids.

**Obs.**—Occurs in Brazil, in the province of Minas Geraes, mining district of Villa Rica, with topaz in chloritic schist; in the auriferous sands of the Orenburg district, southern Ural, near the river Sanárka, with topaz, corundum, cyanite, etc. One Ural crystal measured 3 in. by ⅜ in. In the Glossglockner region of the Austrian Alps on the Gamsgrube, with pericline, rutile, quartz on mica schist; also from the Möllthal with pericline.

Named by Haüy from εὖ, *easily*, and κλάσις, *fracture*, in allusion to the easy cleavage. Haüy states that his name, Euclase, was published by Daubenton in an early issue of his Tableau meth. de Minéraux; but the particular edition of the Tableau (of which several were issued) the author has not been able to learn. Delamétherie, after publishing, in 1792, the name and description, without crediting either to Haüy, in his *Théorie de la Terre*, in 1797, gives Haüy full credit.

First brought to Europe from S. America by Dombey, in 1785.

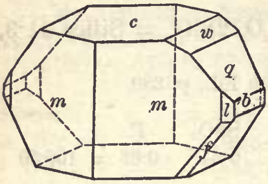
$\delta\delta' = 62°\ 54'$
$\mu\mu' = 84°\ 52'$
$ff' = 97°\ 22'$

Crystals rough and coarse; commonly prismatic and terminated by *c*; sometimes acutely terminated by certain of the pyramids, as *p* (111), *α* (221), *o* (111), or *δ* ($\bar{2}21$). Twinning lamellæ sometimes observed after ignition, Ytterby, Petersson. Also in masses.



Cleavage none. Fracture conchoidal or splintery. Brittle. H. = 6·5–7. G. = 4·0–4·5; normally 4·36–4·47 of anisotropic; 4·24–4·29 isotropic, Petersson; after heating somewhat increased (see below). Luster vitreous to greasy. Color black, greenish black, also brown; in thin splinters nearly transparent, and usually grass-green to olive-green. Streak greenish gray.

Normally doubly refracting and crystalline in structure, but usually isotropic and amorphous. Pleochroism feeble in green varieties; distinct in brown. Optically +. Double refraction normally strong, but variable. Ax. pl. ∥ *b*. $\mathfrak{a}$ (= $Bx_o$) nearly ⊥ *a* like datolite and homilite; $Bx_{a.y} \wedge \dot{c} = +\ 4°$ Dx. $Bx_a \wedge \dot{c} = +\ 7\frac{1}{2}°$ to 9° in green varieties, 12° to 13° in brown (see below) Eichstädt. Axial angles:

$2H_{a.r} = 106°\ 6'$ $2H_{a.y} = 107°\ 18'$ $2H_{a.bl} = 109°\ 27'$ Dx.

$2H_{a.y} = 105°$ $2H_{o.y} = 118°\ 20'$ $\therefore\ 2V_y = 85°\ 28'$ Eichstädt.

**Var.**—In part crystalline in molecular structure, as well as in form, doubly refracting, with optical characters as noted above; color green in thin splinters. Here belongs the normal gadolinite from Hitterö and from Stora Skedevi in Dalarne, Sweden.

More commonly completely amorphous and isotropic, both in the massive form and also in crystals; also both kinds in the same specimen, and again, as seen in a thin section, with brown spots in an isotropic ground-mass. This change in optical structure is due to alteration involving a molecular rearrangement simply, i.e., by paramorphism, for both varieties have the same composition (anal. 1, 2 Petersson). By heating, the amorphous mineral is transformed into the anisotropic and crystalline, and this is accompanied by strong phosphorescence (evolution of light and heat, see below), at the same time there is an increase in the specific gravity and the green color is changed in the thin section to colorless or reddish, and the mineral no longer gelatinizes with acid. The anisotropic mineral is also changed by heating, for while there is no striking phosphorescence, the specific gravity becomes greater, there is an increase in the strength of the double refraction, the color is paler, and gelatinization no longer takes place (Petersson).[5]

Both the anisotropic and isotropic forms become brown by alteration, involving oxidation of the iron and assumption of water. For the former the brown mineral so formed is pleochroic with a larger angle of extinction; for the latter it is still isotropic.

The following are specific gravity determinations: 1, 2, 3, Ytterby; 4, Hitterö; see also the table of analyses.

| After " | G. = | 4·287, 4·456 | 4·356 | 4·419 | 4·668 |

**Comp.**—$Be_2FeY_2Si_2O_{10}$ or $2BeO.FeO.2Y_2O_3.2SiO_2$; written as a basic orthosilicate (Groth) analogous to datolite, etc., the formula is $Be_2Fe(YO)_2(SiO_4)_2$. Percentage composition: Silica 23·9, yttrium oxides (molec. wght. 260) 51·8, iron protoxide 14·3, glucina 10·0 = 100.

The yttrium earths or "gadolinite-earths" (partly replaced by the oxides of cerium, lanthanum, and didymium) form a complex group which has been much studied both chemically and spectroscopically by many chemists, Marignac, Delafontaine, L. de Boisbaudran, Nilson, Cleve, Crookes, and others. The group contains erbium in considerable amount, and also several new elements (ytterbium, scandium, etc.) of more or less definite character have been separated.

Rammelsberg urges that the determinations of the atomic weight of the yttrium metals in gadolinite vary widely; thus he gives the limits from 97·5 Ytterby, Humpidge, and 100 Ytterby, Rg., to 109 Hitterö Rg., and 126 Colorado, Eakins. See further beyond, after analyses, where it appears that for the majority of cases the atomic weight is about 106 or the molecular weight 260.

Prominent recent articles on the gadolinite earths are the following: Cleve and Höglund, Ak. H. Stockh., Bihang, **1**, No. 8, 1872, **2**, No. 12, 1874. Marignac, Bibl. Univ., **61**, 283, 1878, **64**, 97, 1878, C. R., **87**, 578, 1878. Delafontaine, Bibl. Univ., **51**, 48, 1874, **61**, 273, 1878. Nilson, C. R., **88**, 642, 645, 1879, **91**, 118, 1880. Cleve, Öfv. Ak. Stockh., **36**, No. 7, 3, 1879. Crookes, Proc. Roy. Soc., **40**, 502, 1886.

On the atomic weights of the yttrium metals, see Nordenskiöld, G. För. Förh., **8**, 442, 1886 also Rg., l. c.

[e] $Be_2O_3$. [f] Incl. $K_2O$: in 18, 0·15; 19, 0·12; 21, 0·18; 22, 0·20. [g] Incl. $ThO_2$. [h] Ign.

**Pyr., etc.**—The glassy isotropic variety is unchanged in the closed tube, but if heated B.B. the assay gives for a moment a bright light, as if it had taken fire, swells up, cracks open, and becomes grayish green in color without fusing; it has then become anisotropic. The normal anisotropic variety swells into cauliflower-like ramifications and becomes white, rarely glowing (see above, p. 510); the isotropic form, if the alteration has gone too far, also fails to glow. With borax gives an iron reaction. Only slightly acted upon by salt of phosphorus. Decomposed by hydrochloric acid with gelatinization, but not after it has been heated and exhibited the accompanying phosphorescence.

**Obs.**—Occurs principally in pegmatyte veins, often associated with allanite and other minerals containing rare elements, also fluorine compounds. Found at the quarries of Kårarfvet, Broddbo, and Finbo, near Falun in Sweden; also at Ytterby, near Stockholm; chiefly in rounded masses, which are often encircled with a yellow crust, and embedded in coarse-grained granite. At Kårarfvet crystals have been obtained 4 in. long; also in the Torsåker parish, Gestrikland; Karlberg in the Stora Tuna parish, and at St. Skedevi, Dalarne, Sweden. On the island Hitterö in the Flecke fiord, southern Norway, crystals sometimes 4 in. across; on Malö, southeast of Grimstad, Norway. Sparingly in granite veins of the Radauthal in the Harz, associated with allanite (orthite): Schreiberhau in the Riesengebirge, Silesia; Baveno, Italy, in granite; Newcastle, Mourne Mts., Ireland. It is also stated to have been obtained at

---

* First announced as from Burnet Co., Texas, but later shown to have come from Llano Co.

Disko in Greenland; in trap near Galway, Ireland; embedded in granite in Ceylon; but these need confirmation.

In Llano Co., Texas, 5 miles south of Bluffton on the west bank of the Colorado River. It occurs in nodular masses and rough crystals, sometimes up to 40 or 60 pounds in weight, but averaging half a pound, and usually with a reddish or yellow altered exterior. It is embedded in a quartzose pegmatyte, and is associated with allanite, yttrialite, nivenite, fergusonite, cyrtolite, gummite, fluorite, molybdenite, magnetite, feldspar, quartz, mica, etc. The crystals are elongated in the direction of the vertical axis (in one case 10 inches long) and are characterized by the presence of the pyramids *p* (111), *o* ($\bar{1}$11) and *α* (221), the basal plane being nearly or quite wanting; cf. Hidden & Mackintosh, Am. J. Sc., **38**, 474, 1889. At Devil's Head Mt., Douglas Co., Colorado.

According to Petersson the only anisotropic gadolinite is that from Hitterö, Norway, and Stora Skedevi, Dalarne, Sweden; that of the other localities noted is isotropic.

Named after the Swedish chemist, J. Gadolin (1760–1852).

**Alt.**—As noted above, the original crystalline anisotropic gadolinite is for the most part changed molecularly to an amorphous isotropic form. This does not necessarily involve a chemical change, which, however, is involved in the change (p. 510) from the green to the brown variety. Further, the mineral is often altered on the exterior to a brownish red color with waxy luster and further to a yellowish or yellowish brown earthy ocher-like or powdery substance.

The altered gadolinite from Llano Co., Texas, has been examined by Genth (Am. J. Sc., **38**, 198, 1889) with the following results: G. = 3·592.

| $SiO_2$ | $Y_2O_3,Ce_2O_3$ | $Fe_2O_3$ | BeO | MnO | CaO | ign. | quartz |
|---|---|---|---|---|---|---|---|
| 22·11 | 39·20 | 14·53 | 6·03 | 0·22 | 5·58 | 9·30 | 1·03 = 98·00. |

E. Goldsmith has given (J. Analyt. Ch., **4**, 22, 1890) the name *metagadolinite* to a similar alteration product, red in color, with G. = 3·494 and for which he obtained:

$SiO_2$ 18·15 $Ce_3O_4$ 20·66 $Fe_2O_3$ 26·03 YO 21·85 CaO 3·64 MgO 0·21 $H_2O$ 9·76 = 100·30

**Ref.**—[1] Hitterö, Ak. H. Stockh., Bih., **10** (2), No. 18, 1885; the form was first proved to be monoclinic by Dx., Ann. Ch. Phys., **18**, 305, 1869, Min., **2**, xi, 1874. Some early authors made it monoclinic, others orthorhombic. Dx. also early called attention to the isotropic and anisotropic varieties. [2] See Dx., l. c., and Min., **2**, p. xi, 1874. Cf. also Waage, Jb. Min., 696, 1867; Rath, Radauthal, Pogg., 144, 576, 1871; Gdt., Index, **1**, 65, 1887. [3] H. Sj., Öfv. Ak. Stockh., **39**, No. 7, 47, 1882. [4] Eichstädt, l. c. [5] G. För. Förh., **12**, 275–347, 1890.

### 405. YTTRIALITE. *W. E. Hidden* and *J. B. Mackintosh*, Am. J. Sc., **38**, 477, 1889.

Massive. Amorphous.

No cleavage. Fracture conchoidal and splintery. Brittle. H. = 5–5·5. G. = 4·575. Luster vitreous to greasy. Color on the fresh fracture olive-green, tending to drab; this changes on the exterior by alteration to orange-yellow. Translucent, made partially opaque by the presence of minute ragged lines penetrating the mass in all directions.

**Comp.**—A silicate of thorium and the yttrium metals chiefly; oxygen ratio of silicon to bases = 4 : 3, hence equivalent to $R_2O_3.2SiO_2$.

**Anal.**—

| $SiO_2$ | $ThO_2$ | $Y_2O_3$[a] | $Ce_2O_3$ | $(La,Di)_2O_3$ | $UO_3$ | $Al_2O_3$ | FeO | CaO | ign. | |
|---|---|---|---|---|---|---|---|---|---|---|
| 29·17 | 12·00 | 46·50 | 1·86 | 2·94[b] | 0·83 | 0·55 | 3·66[c] | 0·60 | 0·79 | PbO 0·85 = 99·75 |

[a] Yttrium earths including:
A, 22·67 p. c., at. wght. 110·3; B, 5·30, at. wght. 110·53; C, 4·50, at. wght. 114·9; D, 14·03, at. wght. 120.

[b] At. weight 162. [c] Incl. 0·77 MnO.

**Pyr.**—Decrepitates violently in the Bunsen burner; falls to powder when strongly ignited, becoming snuff-brown, infusible and insoluble. Before heating the mineral is soluble in hydrochloric acid.

**Obs.**—Occurs associated with and often implanted upon the gadolinite of Llano Co., Texas (see above). It is sometimes in masses of considerable size (up to 10 pounds); these are orange-yellow on the surface by alteration; this serves to distinguish it from the similar masses of gadolinite associated with it, which are brick-red on the surface. A white crystalline mineral, perhaps tengerite, is observed in the cracks.

Named in allusion to the composition from *yttrium* and *λίθος*, *stone*, the yttrium earths being the chief bases.

Yttrium Silicate *Damour*, L'Institut, 78, 1853. H. = 5–6; scratches glass. G. = 4·391. Color brown. Probably a silicate of yttrium, but composition not determined. B.B. whitens, but infusible. Not soluble in salt of phosphorus. Sulphuric acid heated to 300° C. decomposes it, leaving a siliceous residue.

From the diamond sands of Bahia, Brazil.

## 13. Epidote Group. Orthorhombic and Monoclinic.

Basic Orthosilicates, $H\overset{II}{R}_2\overset{III}{R}_3Si_3O_{13}$ or $\overset{II}{R}_2(\overset{III}{R}OH)\overset{III}{R}_2(SiO_4)_3$,
$\overset{II}{R} = Ca,\overset{II}{Fe}$; $\overset{III}{R} = Al,\overset{III}{Fe},\overset{III}{Mn},Ce$, etc.

### α. *Orthorhombic Section.*

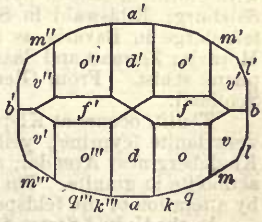
*dd′* = 57° 56′
*ff′* = 37° 52′
*uu′* = 68° 54′
*xx′* = 107° 49′
*ee′* = 128° 10′
*oo′* = 55° 16′
*oo″* = 66° 8′
*oo‴* = 33° 24′
*vv′* = 49° 4′
*pp′* = 42° 11′
*vv‴* = 61° 56′
*pp‴* = 83° 59′

Crystals prismatic, deeply striated or furrowed vertically, and seldom distinctly terminated. A want of symmetry in the development of the pyramidal planes common. Also massive; columnar to compact.

Cleavage: *b* very perfect. Fracture uneven to subconchoidal. Brittle. H. = 6–6·5. G. = 3·25–3·37. Luster vitreous; on the cleavage face, *b*, pearly. Color grayish white, gray, yellowish brown, greenish gray, apple-green; also peach-blossom-red to rose-red. Streak uncolored. Transparent to subtranslucent.

Pleochroism strong in pink varieties, see below. Optically +. Ax. pl. usually ∥ *b*; also ∥ *c*. Bx ⊥ *a*. Dispersion strong, $\rho < v$; also $\rho > v$. Axial angle variable even in the same crystal, also increasing rapidly with rise of temperature.



Tennessee.

| | | | | |
|---|---|---|---|---|
| Bavaria | $2E_r$ = 42° to 44° | $2E_{gr}$ = 50° to 52° | $2E_{bl}$ = 65° to 70° | $\beta_r$ = 1·70 Dx.[3] |
| U. S. | 2E = 94° 59′ at 21½° C. | 100° 12′ at 95½° | 104° 38′ at 146½° | 107° 28′ at 195°·8 Dx. |
| Carinthia | $\alpha$ = 1·696 | $\beta$ = 1·696 | $\gamma$ = 1·702 Lévy-Lcx. | |

The variation in optical characters is probably to be explained (Tschermak) by the existence of twinning lamellæ with (031) as tw. pl. ($c \wedge 031 = 45° 49'$), hence having the axis $\breve{a}$ in common but the $\bar{b}$ axes inclined about 90° to each other; the lamellæ, however, have *m* or *l* (140) as face of contact. Another system of tw. lamellæ with (905) as tw. pl. may also be present.

**Var.**—1. *Ordinary.* Colors gray to white and brown; also green. Usually in indistinct prismatic or columnar forms; also in fibrous aggregates. For zoisite of Rauris, G. = 3·226 Breith.; Saualpe. 3·345 Id.; Moravia, 3·336 Id.; Faltigl, 3·381 Id.; Titiribi, 3·381 Id. *Unionite* is a very pure zoisite, anal. 4.

2. *Rose-red,* or *Thulite.* G. = 3·124; fragile; pleochroism strong: 𝔠 (= $\breve{a}$) yellow, 𝔟 (= $\bar{b}$) deep rose, 𝔞 (= $\dot{c}$) light rose, Lcx.[3]

3. *Compact, massive.* Includes the essential part of most saussurite, which has arisen from the alteration of feldspar. See p. 515.

**Comp.**—$HCa_2Al_3Si_3O_{13}$ or $4CaO.3Al_2O_3.6SiO_2.H_2O$ = Silica 39·7, alumina 33·7, lime 24·6, water 2·0 = 100. The alumina is sometimes replaced by iron, thus graduating toward epidote, which has the same general formula.

**Pyr., etc.**—B.B. swells up and fuses at 3–3·5 to a white blebby mass. Not decomposed by acids; when previously ignited gelatinizes with hydrochloric acid. Gives off water when strongly ignited.

**Obs.**—Occurs chiefly in crystalline schists, especially those characterized by the presence of some one of the amphiboles (actinolite, smaragdite, glaucophane, etc.); thus in amphibolyte, glaucophane schist, eclogyte; also less often in granite.

The original zoisite is that of the eclogyte of the Saualpe in Carinthia (*saualpite*); occurs also with biotite in beds of pyrrhotite at Lamprechtsberg, Carinthia. Other localities are: Rauris in Salzburg; Eibiswald in Styria; Sterzing, Pregratten, Passeyr, Pfitschthal in Tyrol; the Fichtelgebirge in Bavaria, as at Gefrees and Weissenstein; the Saxon Erzgebirge; Marschendorf in Moravia; Zermatt and Saasthal in Switzerland; the island of Syra, one of the Cyclades, in glaucophane schist. From Glen Urquhart, Grantown, Inverness-shire; Loch Garve, Ross shire, in Scotland.

*Thulite* occurs at Kleppan in the parish of Souland in Tellemarken, Norway, with bluish vesuvianite (cyprine), yellowish white garnet, epidote, and fluorite; also at the iron mine of Klodeberg near Arendal; and at Traversella in Piedmont, forming small veins with talc and actinolite in granite. The red color of the *porfido rosso antico* is in part due to thulite produced by alteration of the feldspar (Rosenbusch).

In the United States, found in *Vermont*, at Willsborough, in columnar masses; at Montpelier, bluish gray along with calcite, in mica schist. In *Mass.*, at Chester, in mica schist; at Goshen, Chesterfield, Hinsdale, Heath, Leyden, Williamsburg, Windsor. In *Conn.*, at Milford. In *Penn.*, in W. Bradford and W. Goshen, Chester Co.; in Kennet township and E. Marlboro; Leiperville, Delaware Co.; at Unionville, white (*unionite*) with corundum and euphyllite. In

*N. Carolina*, at the Cullakenee mine in Clay Co., with corundum; also rose-red crystals at the Flat Rock mine, Mitchell Co. In *Tenn.*, at the Ducktown copper mines. In *California*, abundant in the metamorphic rocks, often intimately associated, as at Sulphur Bank, with glaucophane (Becker, l. c.).

This species was instituted by Werner in 1805, first united to epidote by Haüy and Bernhardi independently in 1806, and separated again from epidote on crystallographic grounds by Brooke in 1823. Des Cloizeaux has confirmed Brooke's conclusion by optical examinations, and further has shown that the crystallization is orthometric, instead of clinometric. Thulite is referred to the species by Des Cloizeaux, together with the calcium-epidote from most of the localities mentioned in connection with the analyses.

*Zoisite* was so named after Baron von Zois, from whom Werner received his first specimens; and *Thulite* after Thule, an ancient name of Norway.

SAUSSURITE. Jade (fr. near L. Geneva) *H. B. de Saussure*, Voy. Alpes, **1**, § 112, 1780. Bitterstein, Schweizerische Jade, *Höpfner*, Mag. Helvet., **1**, 291, Bergm. J., 448, 1788. Nephrite pt. *Wern.* Lehmanite *Delameth.*, T. T., **2**, 354. Jade tenace, Jade de Saussure, *H.*, Tr , **4**, 1801. Saussurite *T. de Saussure*, J. Mines, **19**, 205, 1806. Var. of Zoisite *T. S. Hunt*, Am. J. Sc., **25**, 437, 1858, **27**, 336, 1859.

A tough compact mineral substance with splintery fracture; H. = 6·5–7; G. = 3·0–3·4; color varying from white or nearly so to gray, greenish gray, bluish green; translucent to nearly opaque. For the most part derived from the alteration of a feldspar by a process of "saussuritization," and rarely, if ever, a homogeneous mineral.

In composition it often approaches zoisite, as shown by Hunt (l. c.), of which it has been regarded as a soda-bearing variety. It has been proved by Cathrein and others[1], however, that while zoisite is often a prominent constituent, there is usually present a plagioclase feldspar, often near albite and probably of secondary origin; also rarely orthoclase in varying amount, and garnet, with tremolite, chlorite, etc., as accessories. In many cases the saussurite is of so fine-grained texture that it is only with difficulty resolved by the microscope.

The place of the zoisite is sometimes taken by epidote, when sufficient iron for the latter mineral is present. Further some so-called saussurite contains no zoisite, the name having been given, for example, to some compact labradorite; also to some substances which have proved to have the composition of garnet. Cf. Michael, Jb. Min., **1**, 39, 1888. Cathrein also describes the change of garnet to saussurite, Zs. Kr., **10**, 444, 1885. Roepper has described a calcium-potash pseudomorph after anorthite from Franklin, N. J., with G. = 3·06–3·10, Am. J. Sc., **16**, 364, 1878.

The original saussurite was from the vicinity of Lake Geneva. G. = 3·261 de Saussure; 3·365–3·385. Hunt; H. = 6·5–7; color pale bluish green, greenish gray, to white or nearly so; very tough. Not attacked by acids. It was named after the elder H. B. de Saussure (1740–1799) by his son, Th. de Saussure (1767–1845). Hütlin and Pfaffius have described a saussurite which occurs with serpentine in the Schwarzwald. It forms with smaragdite the euphotide of the Alps, a rock which, as a result of glacier action, is widely distributed in boulders over the valley of the Rhone, and the country about Lake Geneva; the boulders, as ascertained by Prof. Guyot, were derived from the chain of the Saasgrat, through the valley of the Saas, and are distributed to a distance of 150 miles from this place of origin. Also present in saussurite-gabbro and related rocks of Corsica, Piedmont, the Fichtelgebirge, Scandinavia, the Lizard; in the greenstones of the Lake Superior region (G. H. Williams, Bull. **62**, U. S. G. Surv.).

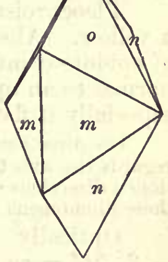


Figs. 1, Arendal, Haid. 2, Sulzbach, Bkg., projection on *b* (010). 3, Ural, Kk. 4, Achmatovsk, Kk. 6, Achmatovsk, after Kk., projection on plane ⊥ *ċ*. 5, 7, 8, common forms; 7, 8, with axis ⊥ *b* erect. 9, Elba, Artini. 10, Colorado, Bodewig. 11, *Bucklandite*, Achmatovsk, Kk.

The species zoisite and epidote, similar in composition, are also closely related in form and hence to be regarded as isomorphous though belonging to different crystalline systems. Thus, as suggested by Tschermak and others (cf. 5th Ed., p. 292), the corresponding planes may be regarded as:

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Zoisite | *b* (010) | *c* (001) | *m* (110) | *u* (021) | *m'''* (110) | *o* (111) | *o'''* (1$\bar{1}$1) |
| Epidote | *a* (100) | *b* (010) | *c* (001) | *m* (110) | *r* (101) | *o* (011) | *n* ($\bar{1}$11) |

| Zoisite | | | Epidote (cf. f. 4) | | |
|---|---|---|---|---|---|
| *mm'''* | (110 ∧ 1$\bar{1}$0) | = 63° 34′ | *cr* | (001 ∧ $\bar{1}$01) | = 63° 42′ |
| *oo'''* | (111 ∧ 1$\bar{1}$1) | = 33° 24′ | *on* | (011 ∧ $\bar{1}$11) | = 33° 55½′ |
| *uu'* | (021 ∧ 0$\bar{2}$1) | = 68° 54′ | *mm'* | (110 ∧ $\bar{1}$10) | = 70° 4′ |
| *mo* | (110 ∧ 111) | = 56° 56′ | { *co* | (001 ∧ 011) | = 58° 28′ |
| | | | { *rn* | ($\bar{1}$01 ∧ $\bar{1}$11) | = 54° 45′ |
| *oo''* | (111 ∧ $\bar{1}$11) | = 66° 8′ | { *oo'''* | (011 ∧ 10$\bar{1}$) | = 63° 4½′ |
| | | | { *nn'''* | ($\bar{1}$11 ∧ 11$\bar{1}$) | = 70° 29′ |

Brögger, however, prefers to regard the planes in the prismatic zone as corresponding thus:

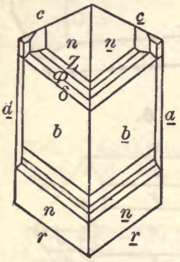
| | | | | | |
|---|---|---|---|---|---|
| Zoisite | 100 | 120 | 130 | 140 | 210 |
| Epidote | 102 | 102 $\bar{3}$02 | 101 $\bar{2}$01 | 302 $\bar{5}$02 | $\bar{1}$04 $\bar{3}$04 |

Further by exchanging, for zoisite, the axes *c* and *b* and *b* and *a*, also by making the dome (021) = (110): further, taking for epidote *i* ($\bar{1}02$) as (001), and *r* ($\bar{1}01$) as (101), he calculates:

| | $a' : b' : c'$ | | |
|---|---|---|---|
| Zoisite | 1·4458 : 1 : 0·9023 | $\alpha'\ \beta'\ \gamma' = 90°$ | |
| Epidote | 1·4406 : 1 : 0·8903 | $\alpha'\ \gamma' = 90°$ | $\beta' = 81°\ 3'$ |

Twins: tw. pl. (1) *a* common (f. 10, 12), often as embedded tw. lamellæ; (2) *c* rather rare. Crystals usually prismatic ∥ the axis $\overset{|}{b}$ and terminated at one extremity only; passing into acicular forms. The planes in the zone, *ac*, are usually deeply striated. When terminated by *n* or *o* simply (f. 5, 7, 8), the crystals often have a deceptive orthorhombic aspect, cf. also f. 4. The terminal angles *mm'* ($110 \wedge \bar{1}10 = 70°\ 4'$) and *nn'''* ($\bar{1}11 \wedge \bar{1}1\bar{1} = 70°\ 29'$) approximate closely to each other and hence these forms can be easily confounded. Prismatic crystals developed ∥ $\acute{c}$ are rare (f. 9, 10). Also fibrous, divergent, or parallel; granular, particles of various sizes, sometimes fine granular, and forming rock-masses.

12.



12, Sulzbach, Bkg.

Cleavage: *c* perfect; *a* imperfect. Fracture uneven. Brittle. H. = 6–7. G. = 3·25–3·5. Luster vitreous; on *c* inclining to pearly or resinous. Color pistachio-green or yellowish green to brownish green, greenish black, and black; sometimes clear red and yellow; also gray and grayish white, rarely colorless. Streak uncolored, grayish. Transparent to opaque: generally subtranslucent.

Pleochroism strong: vibrations ∥ $\mathfrak{c}$ green, $\mathfrak{b}$ brown and strongly absorbed, $\mathfrak{a}$ yellow. Absorption usually $\mathfrak{b} > \mathfrak{c} > \mathfrak{a}$; but sometimes $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$ in the variety of epidote common in rocks. Often exhibits idiophanous figures[4], best in sections normal to an optic axis, but often to be observed in natural crystals (Sulzbach), especially if flattened ∥ *r* ($\bar{1}01$).

The directions of maximum absorption and the axes of elasticity do not coincide except as regards the axis $\mathfrak{b}$ which is ∥ $\overset{|}{b}$, the crystallographic axis of symmetry; nor are the first mentioned directions (axes of absorption) at right angles to each other. Exhaustive investigations of these phenomena have been given Pulfrich. Ramsay, *et al.*[4]

Optically −. Double refraction very strong. Ax. pl. ∥ *b*. $Bx_{a.r} \wedge \acute{c} = -2°\ 56' = \mathfrak{c}a$. $Bx_{a.gr} \wedge \acute{c} = -2°\ 26'$ Klein. Hence $\mathfrak{c} \perp a$ (100) nearly. Dispersion inclined, strongly marked; of the axes feeble, $\rho > v$. One optic axis nearly ⊥ *r* (101), the other slightly inclined to *c* (001). Axial angles, Klein[3]:

| | | | |
|---|---|---|---|
| | $2H_{a.r} = 91°\ 26'$ | $2H_{a.y} = 91°\ 20'$ | $2H_{a.gr} = 91°\ 12'$ |
| | $2H_{o.r} = 144°\ 56'$ | $2H_{o.y} = 145°\ 38'$ | $2H_{o.gr} = 146°\ 36'$ |
| ∴ | $2V_{a.r} = 73°\ 48'$ | $2V_y = 73°\ 39'$ | $2V_{gr} = 73°\ 26'$ |
| Also | $\beta_r = 1·75405$ | $\beta_y = 1·75702$ | $\beta_{gr} = 1·76213$ |
| | $\alpha_r = 1·76766$ | $\gamma_r = 1·73053$ | |

**Var.**—Epidote has ordinarily a peculiar yellowish green (pistachio) color, seldom found in other minerals. But this color passes into dark and light shades—black on one side, and brown on the other; red, yellow, and colorless varieties also occur.

Var. 1. *Ordinary.* Color green of some shade, as described, the pistachio tint rarely absent. (*a*) In crystals. (*b*) Fibrous. (*c*) Granular massive. (*d*) *Scorza* is epidote sand, of the usual green color, with quartz from the gold washings of the river Aranyos, near Muska in Transylvania. The Arendal epidote (*Arendalite*) is mostly in dark green crystals: that of Dauphiné (*Thallite, Delphinite, Oisanite*) in yellowish green crystals, sometimes transparent; found near Bourg d'Oisans. *Puschkinite* includes crystals from the auriferous sands of Ekaterinburg, Ural; G. = 3·066; named after Pushkin, a Russian senator. *Achmatite* is ordinary epidote, in crystals, from Achmatovsk, Ural. *Escherite* is a brownish yellow, somewhat greenish epidote, from St. Gothard. A variety from Garda, Hoste Is., Terra del Fuego, has been described which is colorless and resembles zoisite (anal. 17).

2. The so-called *Bucklandite* from Achmatovsk, described by Hermann, is black with a tinge of green, and differs from ordinary epidote in having the crystals nearly symmetrical (f. 11), and not, like other epidote, lengthened in the direction of the orthodiagonal. G. = 3·51. Hermann's *Bagrationite*, from Achmatovsk, appears to be essentially the same mineral, agreeing with it

in angles, according to Hermann (Bull. Soc. Nat. Moscow, **35**, 248, 1862), and having G. = 3·46, while the original bagrationite of Koksharov is a variety of allanite (p. 523). It differs from bucklandite in containing a little cerium.

3. *Withamite.* Carmine-red to straw-yellow; strongly pleochroic; deep crimson and straw-yellow; H. = 6–6·5; G. = 3·137; in small radiated groups. From Glencoe, in Argyleshire, Scotland. Named after Dr. Henry Witham of Glencoe. It is stated to contain manganese, and sometimes referred to piedmontite, but an analysis by Heddle (anal. 15) gives only 0·14 MnO, Min. Mag., **5**, 15, 1882. Cf. Lcx., Bull. Soc. Min., **9**, 75, 1886.

*Beustite* is a grayish white to ash-gray mineral. From near Predazzo in the Tyrol. G. = 2·859–2·877, Breith. Its identity with epidote has not certainly been proved.

**Comp.**—$HCa_2(Al,Fe)_3Si_3O_{13}$ or $H_2O.4CaO.3(Al,Fe)_2O_3.6SiO_2$, the ratio of aluminium to iron varies commonly from 6 : 1 to 3 : 2. Percentage composition:

| Al : Fe | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|
| 1 : 0 | 39·67 | 33·71 | — | 24·64 | 1·98 | = | 100 |
| 5 : 1 | 38·44 | 27·23 | 8·53 | 23·88 | 1·92 | = | 100 |
| 4 : 1 | 38·20 | 25·98 | 10·18 | 23·73 | 1·91 | = | 100 |
| 3 : 1 | 37·87 | 24·13 | 12·60 | 23·51 | 1·89 | = | 100 |
| 2 : 1 | 37·29 | 21·13 | 16·55 | 23·16 | 1·87 | = | 100 |
| 0 : 1 | 33·30 | — | 44·35 | 20·68 | 1·67 | = | 100 |

Most early analysts failed to recognize the presence of the water, and when found it was usually referred to alteration. The correct formula was first established by Tschermak, who (Min., 1883) makes it a basic orthosilicate containing (CaOH), while Groth assumes the presence of (AlOH).

**Pyr., etc.**—In the closed tube gives water on strong ignition. B.B. fuses with intumescence at 3–3·5 to a dark brown or black mass which is generally magnetic. Reacts for iron and sometimes for manganese with the fluxes. Partially decomposed by hydrochloric acid, but when previously ignited, gelatinizes with acid. Decomposed on fusion with alkaline carbonates. G. of Arendal epidote changes on ignition, from 3·409 to 2·984.

**Obs.**—Epidote is common in many crystalline rocks, as syenite, gneiss, mica schist, hornblendic schist, serpentine, and especially those that contain the ferriferous varieties of amphibole. It often accompanies beds of magnetite or hematite in such rocks. It is sometimes found in geodes in trap; and also in sandstone adjoining trap dikes as a result of contact metamorphism. It also occurs at times in nodules in different quartz-rocks or altered sandstones. It is a constituent of much so-called saussurite formed from plagioclase feldspar (p. 515). It is associated often with quartz, pyroxene, feldspar, axinite, chlorite, etc.

It sometimes forms with quartz an epidote rock, called *epidosyte*. A similar rock exists at Melbourne in Canada. A gneissoid rock consisting of flesh-colored orthoclase, quartz, and epidote from the Unaka Mts. (N. C. and Tenn.) has been called unakyte.

Beautiful crystallizations come from Bourg d'Oisans, Dauphiné; the Ala valley and Traversella, in Piedmont; Elba; Zermatt in the Valais; near Guttannen in the Haslithal; at Kaverdiras and Baduz in the valley of Tavetsch (the latter sometimes referred to zoisite, but optically epidote, Dx.); Monzoni in the Fassathal, Zillerthal in Tyrol, sometimes in rose-red and greenish crystals of small size, resembling *thulite;* the Saualpe in Carinthia. The Knappenwand in the Untersulzbachthal, Pinzgau, has since 1866 furnished large quantities of crystals beautiful in size, complexity of form, luster and transparency; they occur in crevices in an epidotic schist associated with asbestus, adularia, fine crystals of apatite, also titanite, scheelite; also well crystallized from the Krimler-Achenthal, near Kriml; the Habachthal and Hollersbach in Tyrol; Striegau, Silesia; Zöptau, Moravia; Arendal in Norway; Nordmark, Wermland, Sweden; the Achmatovsk mine near Zlatoust, Ural; from the Ilmen Mts.; Ekaterinburg. In Brazil with the green tourmaline of Minas Geraes.

In N. America, occurs in *N. Hamp.*, at Franconia, crystallized and granular. with magnetite; Warren with quartz and pyrite. In *Mass.*, at Hadlyme and Chester, in crystals in gneiss; at Athol, in syenitic gneiss, in fine crystals, 2 m. S.W. of the center of the town; Newbury. in limestone; at Somerville with prehnite; at Nahant, poor, in trap; at Rowe, at the pyrite mine with gahnite. In *Rhode Island*, at Cumberland, in a kind of trap. In *Conn.*, at Haddam, in large splendid crystals; on Hosmer Mt., ½ mile S.W. of Willimantic. In *N. York*, 2 m. S.E. of Amity, in quartz; 2 m. S. of Carmel, Putnam Co., with hornblende and garnet; 2 m. S. of Coffee's, Monroe, Orange Co.; 6 m. W. of Warwick, pale yellowish green, with titanite and pyroxene; on New York island on the East river, near 38th St. In *N. Jersey*, at Franklin, massive; at Roseville in Byram township, Sussex Co., in good crystals. In *Penn.*, at E. Bradford; on John Balderson's farm, Kennett township, Chester Co. In *Maryland*, at Webb's mine, Cumberland. In *N. Carolina*, from the gold-washings of Rutherford Co.; fine crystals at Hampton's, Yancey Co.; White's mill, Gaston Co.; Franklin, Macon Co.; in crystals and crystalline masses in quartz at White Plains, Alexander Co. In *Michigan*, in the Lake Superior region, at many of the mines; at the Norwich mine, beautifully radiated with quartz and native copper. In *Colorado*, in the Pike's Peak region (fig. 10); also in calcite at the Calumet mine, Calumet, Chaffee Co. In *Canada*, at St. Joseph, Beauce Co., Quebec, in a concretionary argillaceous rock.

*Epidote* is one of Haüy's crystallographic names, derived from the Greek ἐπίδοσις, *increase*, and translated by him, "qui à reçu un accroissement," the base of the prism (rhomboidal prism) having one side longer than the other. In its introduction Haüy set aside three older names. Thallite (from θαλλός, color of young twigs, alluding to the green color) was rejected because it was based on a varying character, color; *Delphinite* and *Arendalite*, because derived from localities. But the name *Epidote* is now so involved in geological as well as mineralogical literature that the law of priority cannot well do the justice demanded of it. Werner's name *Pistacite*, from πιστάκια, *the pistachio-nut* (referring to the color), was not proposed as early as thallite or epidote.

**Alt.**—Epidote is less liable to alteration than most of the silicates, partly because the iron it contains is mostly, when not wholly, in the state of sesquioxide.

**Artif.**—Epidote has not, as yet, been found among the crystallizations of furnace slags, or formed in the laboratory of the chemist, although it has been a frequent result of the action of heat and steam on ferruginous sandstones accompanying the ejection of doleryte and other eruptive rocks.

**Ref.**—[1] Vh. Min. Ges., **15**, 31, 1880, and Min. Russl., **8**, 44; from measurements of crystals from Untersulzbach; the agreement of measured and calculated angles shows that these elements are probably more precise than those of Koksharov, Sr., (Min. Russl., **3**, 268, 1858,) generally accepted hitherto, viz., 1·58073 : 1 : 1·80574, $\beta = 64° 36'$. The position here taken is that of Marignac and now adopted by most authors; with Mohs and Naumann (also Dana, earlier Eds.) $a$ (T) = $\bar{1}01$, $c$ (M) = 100, $z$ = $\bar{1}11$, $l$ = 001, etc.

[2] See Bkg. (Zs. Kr., **2**, 321, 1878) for a list of planes with early authorities, etc.; he enumerates 220 planes, including 147 determined by him, but many are doubtful, especially those (about 100 in number) in the striated orthodome zone. Cf. also Gdt., Index, **1**, 557, 1886, and recently Flink, Artini (see below), and Hintze, Min., **2**, 210 *et seq.*, 1890. The list here given includes all the common planes and some others.

Monoclinic. Axes $\grave{a} : \bar{b} : \dot{c} = 1{\cdot}6100 : 1 : 1{\cdot}8326$; $\beta = {}^*64° 39' = 001 \wedge 100$ Laspeyres[1].

$100 \wedge 100 = 55° 30'$, $001 \wedge \bar{1}01 = 63° 30\frac{1}{2}'$, $001 \wedge 011 = 58° 52\frac{1}{2}'$.

**Forms**[1]: *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$), *c* (001, *O*), *m* (110, *I*); *e* (101, – 1-$\bar{i}$), *i* ($\bar{1}$02, $\frac{1}{2}$-$\bar{i}$), *r* ($\bar{1}$01, 1-$\bar{i}$); *n* ($\bar{1}$11, 1).

Angles: *mm‴* = 111° 0′, *ci* = 34° 13′, *cx* = 63° 30½′, *a′i* = 81° 8′, *cn* = 75° 16′, *a′n* = 69° 22½′, *nn′* = 110° 29′.

Twins: tw. pl. *a*, often polysynthetic; also *c* very rare. Crystals prismatic ‖ $\bar{b}$ like ordinary epidote, but distinct forms rare and faces usually dull. Also massive.

Cleavage: *c* perfect; *a* less so. Fracture uneven. Fragile. H. = 6·5. G. = 3·404 Breith. Luster vitreous; slightly pearly on other faces. Color reddish brown and reddish black; in very thin splinters columbine-red. Streak reddish. Opaque to subtranslucent.

Pleochroism strong: $\mathfrak{c}$ red, $\mathfrak{b}$ amethyst to pink, $\mathfrak{a}$ orange to citron-yellow. Absorption $\mathfrak{a} > \mathfrak{b} > \mathfrak{c}$. Optically +. Ax. pl. ‖ *b*. $Bx_{a.r} \wedge \dot{c} = +82° 34'$, $Bx_{a.y} = 83° 19'$, or $Bx_{o.r} \wedge \dot{c} = -7° 26'$, $Bx_{o.y} = -6° 41'$; hence $\mathfrak{c}$, as in epidote, nearly ⊥ *a*, Lasp.[2], St. Marcel. For Japanese piedmontite, extinction-angle $= \mathfrak{a} \wedge \dot{c} = Bx_o \wedge \dot{c} = -3°$ Kotō. Dispersion inclined, strong. Axial angles, Dx.:

$$2H_a = 82°\text{–}90° \qquad 2H_o = 121°\text{–}126°$$

**Comp.**—$HCa_2(Al,Mn,Fe)_3Si_3O_{13}$ or $H_2O.4CaO.3R_2O_3.6SiO_2$. If Al : Mn : Fe = 3 : 2 : 1, the percentage composition is: Silica 33·6, alumina 14·3, iron sesquioxide 14·9, manganese sesquioxide 14·7, lime 20·9, water 1·7 = 100.

**Anal.**—1, Rammelsberg, Min. Ch., 595, 1875, also Lasp., l. c. Most earlier analyses (5th Ed., p. 285) neglect the water. 2, Takayama, J. Coll. Sc., Japan, **1**, 303, 1887. 3, Igelström, Öfv. Ak. Stockh., **24**, 11, 1867. 4, Flink, Ak. H. Stockh., Bihang, **13** (2), No. 7, 52, 1888; also Svensson and Tamm, quoted by Flink.

[a] MnO. [b] Ignition, separately determined, 0·94.

**Pyr., etc.**—B.B. fuses with intumescence at 3 to a black lustrous glass. Gives strong reactions for manganese with the fluxes, and also for iron. Not decomposed by acids, but when previously ignited gelatinizes with hydrochloric acid. Decomposed on fusion with alkaline carbonates.

**Obs.**—Occurs at St. Marcel, in the valley of Aosta, in Piedmont, in braunite with quartz, greenovite, violan, and tremolite. Common in the crystalline schists of Japan at numerous points, with quartz in piedmontite-schist, also as an accessory in glaucophane-schist, and in general in the chlorite-sericite gneiss of the Archæan. It sometimes occurs as a nucleus surrounded by ordinary epidote. Also in the mica schists of the Ile de Groix, Brittany, and in England.

A manganesian epidote (anal. 3, 4) occurs in crystalline limestone at Jakobsberg, Nordmark, Sweden[1].

**Ref.**—[1] Zs. Kr., **4**, 435, 1880. Flink observed on the manganepidote (anal. 4) of Jakobsberg (cf. epidote) *a* (100), *c* (001), *m* (110), *η* (120), **m** (102), *i* ($\bar{1}02$), *r* ($\bar{1}01$), *o* (011), *n* ($\bar{1}11$) with $\grave{a} : \bar{b} : \acute{c} = 1{\cdot}5807 : 1 : 1{\cdot}8057$, $\beta = 64° 36'$. Optically —. $\mathfrak{a} \wedge \acute{c} = Bx_{a.r} \wedge \acute{c} = -4° 34'$, $Bx_{a.y} \wedge \acute{c} = -5° 20'$, $2H_{a.r} = 86° 52'$, $2H_{o.r} = 89° 26'$, $\therefore 2V_r = 88° 40\frac{1}{3}'$. In composition and optical characters it lies between ordinary epidote and piedmontite.

[2] Absorption phenomena, etc., cf. Lasp., l. c.; Dx., Bull. Soc. Min., **6**, 25, 1883.

**409. ALLANITE,** or ORTHITE. Crystallized Gadolinite? (fr. Greenland) *T. Allan*, Tr. R. Soc. Edinb., **6**, 345 (read Nov. 1808) = Allanite *Thomson*, ib., 371 (read Nov. 1810); Phil. Twins: tw. pl. *a*; also *c* rare. Crystals often flat tabular ‖ *a*; also long and slender to acicular prismatic by elongation ‖ axis $\acute{b}$ Also massive and in embedded angular or rounded grains.

Cleavage: *a* and *c* in traces; also *m* sometimes observed. Fracture uneven or subconchoidal. Brittle. H. = 5·5–6. G. = 3·5–4·2 Luster submetallic, pitchy, or resinous—occasionally vitreous. Color pitch-brown to black, either brownish, greenish, grayish, or yellowish. Streak gray, sometimes slightly greenish or brownish. Subtranslucent to opaque.

In part normally anisotropic and biaxial with strong pleochroism: $\mathfrak{c}$ brownish yellow, $\mathfrak{b}$ reddish brown, $\mathfrak{a}$ greenish brown. Optically —. Double refraction weak and variable. Ax. pl. ‖ *b*. $Bx_a \wedge \acute{c} = 32\frac{1}{2}°$ approx. $\beta = 1·682$ Lcx.

According to Brögger, optically —. Ax. pl. ⊥ *b* and inclined to $\acute{c}$ — $37\frac{1}{2}°$. Sognsvand. Also for other occurrences, Arendal, Hitterö extinction-angle 34°–37°, 40°–41°. Also isotropic and amorphous by alteration analogous to gadolinite[8] and homilite.

**Var.**—This species, while closely like epidote in crystallization, varies much in the results of analyses, and also in external appearance. The more prominent ways of variation are the following: (1) The crystals are sometimes broad tabular, and sometimes very long acicular. (2) The crystals, when well-formed, often manifest no double refraction, as Des Cloizeaux observed, and as has been more closely studied by Brögger. (3) The amount of water present varies from 2 p. c. to 17 p. c., and the hardness and specific gravity correspondingly, the kinds containing the most water being lowest; and, in some, G. not exceeding 2·53. (4) There is also much diversity in pyrognostic and other chemical characters, as explained beyond.

The varieties that have been distinguished are as follows:

1. *Allanite.* In tabular crystals or plates, the crystals sometimes 8 to 10 in. long, 5 to 6 wide, and an inch or so thick. Color black or brownish black. G. = 3·50–3·95. Named after T. Allan, the discoverer of the mineral, and found among specimens from East Greenland, brought to Scotland by Giesecke early in the century. *Cerine* is the same thing, named by Hisinger, having H. = 6; G. = 3·77–3·8; luster weak, greasy; and being subtranslucent in thin splinters.

*Bucklandite* is anhydrous allanite in small black crystals from a magnetite mine near Arendal, Norway. It was referred here by v. Rath on the ground of the angles and physical characters (Pogg., **113**, 281, 1861). That of the Laacher See is also shown to have the angles of allanite by Rath (l. c.); the angles are those cited above as the angles of the species. *Tautolite Breith.* is also from the trachyte of the Laacher See and is probably the same species.

2. *Uralorthite* is allanite in large prismatic crystals from the Ilmen Mts., near Miask. H. = 6; G. = 3·41–3·60 Herm.; 3·647 Rg. It is pitch-black, gives a gray powder, and is nearly anhydrous.

3. *Bagrationite.* Occurs, according to Koksharov, in black crystals, which are nearly symmetrical like the bucklandite of Achmatovsk, and not lengthened, like uralorthite, in the direction of the orthodiagonal. Angles the same with those of uralorthite. H. = 6·5. G. = 3·84 Kk. Streak dark brown. B.B. intumesces and forms a black, shining, magnetic pearl. In powder not attacked by hot hydrochloric acid or by boiling nitric acid. Named after the discoverer, P. R. Bagration. From Achmatovsk, Ural. Hermann has described and analyzed what he calls *bagrationite*, from Achmatovsk, which he states has the angles of the bucklandite *of Achmatovsk*, and which, therefore, is true epidote (q.v.). The analyses by Hermann sustain this reference.

4. *Orthite* included, in its original use, the slender or acicular prismatic crystals, often a foot long, containing some water. But these graduate into massive forms, and some orthites are anhydrous, or as nearly so as much of the allanite. The name is from ὀρθός, *straight*. The tendency to alteration and hydration may be due to the slenderness of the crystals, and the consequent great exposure to the action of moisture and the atmosphere. Luster vitreous to greasy. Some authors use orthite as the comprehensive name of the species.

5. *Xanthorthite*, of Hermann, is yellowish and contains much water, and is apparently an altered variety: G. = 2·78–2·9. Named from ξανθος, *yellow*, and *orthite*.

6. *Pyrorthite* of Berzelius is an impure altered orthite-like mineral, in long prisms of rather loose texture, containing as its principal impurity some carbonaceous material (over 30 p. c.), and showing this in its burning before the blowpipe. Named from πῦρ, *fire*, and *orthite*. From Kårarfvet, near Falun, Sweden.

**Comp.**—Like epidote $H\overset{II}{R}\overset{III}{R}_3Si_3O_{13}$ or $H_2O.4RO.3R_2O_3.6SiO_2$ with $\overset{II}{R}$ = Ca and Fe, and $\overset{III}{R}$ = Al,Fe, the cerium metals Ce,Di,La, and in smaller amount those of the yttrium group. Some varieties contain considerable water, but probably by alteration.

On the composition of allanite, see Rg., Zs. G. Ges., **24**, 60, 1872.

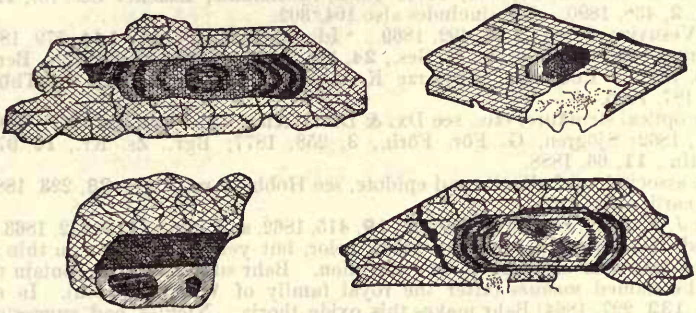
Soc., **24**, 42, 1887. 38, 39, Genth, Am. J. Sc., **40**, 118, 1890. 40, Eakins, Proc. Colorado Sc. Soc., **2**, 32, 1885. Also 5th Ed., pp. 287, 288.—For analyses see the preceding page.

**Pyr., etc.**—Some varieties give much water in the closed tube and all kinds yield a small amount on strong ignition. B.B. fuses easily and swells up (F. = 2·5) to a dark, blebby, magnetic glass. With the fluxes reacts for iron. Most varieties gelatinize with hydrochloric acid, but if previously ignited are not decomposed by acid.

**Obs.**—Occurs in albitic and common feldspathic granite, gneiss, syenite, zircon-syenite, porphyry. Also in white limestone, and often in mines of magnetic iron. Rather common as an accessory constituent in many rocks, as in andesyte, dioryte, dacyte, rhyolyte, tonalyte of Mt. Adamello (Rath), the scapolite rocks of Ödegaarden, Norway (Lcx.), etc. Cf. Iddings and Cross, Am. J. Sc., **30**, 108, 1885; Lcx., Bull. Soc. Min., **12**, 210, 1889. Sometimes inclosed as a nucleus in crystals of the isomorphous species, epidote; as at Sillböle, Finland and other points (Nordenskiöld, F. J. Wiik, Min-Saml. Helsingfors, fig. 7, 1887, Lcx., l. c., *et al.;* similarly at Ilchester, Md., Hobbs[9]).



Allanite enclosed within epidote, Ilchester, Md., Hobbs[9].

*Allanite* occurs in Greenland, in granite; at Criffel, in Scotland, in small crystals; at Jotun Fjeld in Norway, in a kind of porphyry, and at Snarum, in albite, along with rutile and apatite; at the Plauensche Grund, near Dresden; in granite at the Schwarze Krux near Schmiedefeld and elsewhere in the Thüringer Wald; in the granite of Striegau, Silesia. At Vesuvius in ejected masses with sanidine, sodalite, nephelite, hornblende, etc. Similarly in trachytic ejected masses at the Laacher See (*bucklandite*) with sanidine, mica, hornblende, etc. In granular limestone at Auerbach on the Bergstrasse, but rare. *Cerine* occurs at the Bastnäs mine, in Westmanland, Sweden, with cerite, hornblende and chalcopyrite.

*Orthite* occurs in acicular crystals sometimes a foot long at Finbo near Falun in Sweden; at Ytterby and Skeppsholm near Stockholm, in black vitreous masses disseminated through gneiss; also at Kragerö, Hitterö, and Fille Fjeld in Norway; at Sillböle; also at Stansvik, parish of Helsinge, in Finland, forming the nucleus of epidote crystals; *uralorthite* occurs with small crystals of zircon in flesh-red feldspar at Miask in the Ural; *bagrationite* at the Achmatovsk mine near Zlatoust.

In *Mass.*, at the Bolton quarry; at S. Royalston, in boulders; in Athol, on the road to Westminster, in gneiss; at Swampscot, near Marblehead. In *Conn.*, at Allen's vein, at the gneiss quarries, Haddam. In *N. York,* near West Point, in tabular cryst.; Moriah, Essex Co., with magnetite and apatite, some cryst. 8–10 in. long, 6–8 broad, and 1–2 thick; at Monroe, Orange Co. In *N. Jersey,* at Franklin with feldspar and magnetite. In *Penn.*, at S. Mountain, near Bethlehem, in large crystals; at E. Bradford in Chester Co. (called orthite, G. = 3·5); at Easton, Northampton Co.(?); Pricetown, near Reading, Berks Co., abundant. In *Virginia,* in large masses in Amherst Co.; also in Bedford, Nelson, and Amelia counties. In *N. Carolina,* in crystals at the hiddenite mine in Alexander Co., with emerald, etc.; also in Mitchell Co., at the Wiseman mica mine; at Balsam Gap, Buncombe Co.; massive in large quantities near Bethany Church, Iredell Co.; also Democrat P. O., Madison Co.; at Brindletown, and at the zircon mines in Henderson Co. At the Devil's Head Mt., Douglas Co., Colorado. As an accessory rock constituent it has been identified in many localities (cf. above). In *Canada,* at Bay St. Paul, Charlevoix Co., Quebec; in a rock composed of labradorite and hypersthene from Lake St. John, Chicoutimi Co., Quebec; at Hollow lake, head-waters of the S. Muskoka, Ontario.

**Alt.**—The hydrous varieties of allanite or orthite (see several of the analyses given on p. 524, also *vasite* below) are properly altered forms of the species. They often contain carbon dioxide. It is probable that the carbonates of lanthanum and of cerium proceed at times from the alteration of allanite.

The alteration product of the allanite of Amherst Co., Va., which forms an earthy pulverulent crust about the original mineral (anal. 1, J. A. Cabul, Ch. News, **30**, 141, 1872), has been analyzed by J. R. Santos (ibid., **38**, 95, 1878), anal. 2, 3:

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | $Ce_2O_3$ | $(La,Di)_2O_3$ | $Yr_2O_3$ | CaO | MgO | BeO | $H_2O$ | |

[9] On the association of allanite and epidote, see Hobbs, Am. J. Sc., **38**, 223, 1889, who gives in detail the earlier literature.

WASITE *J. F. Bahr*, Öfv. Ak. Stockh., **19**, 415, 1862, and Pogg., **119**, 572, 1863. Vasite. A much altered allanite, of a brownish black color, but yellowish brown in thin splinters and powder; with traces of cleavage in one direction. Bahr supposed it to contain the oxide of a new metal he named *wasium* (after the royal family of Wasa, Sweden). In a later paper (Lieb. Ann., **132**, 227, 1864) Bahr makes this oxide thoria. Nicklès had suggested previously that it might be impure cerium. From Rönsholm, an island near Stockholm. Analyses by Engström are (ref., p. 525) as follows:

| | $SiO_2$ | $ThO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Y_2O_3$ | $Er_2O_3$ | $Ce_2O_3$ | $Di_2O_3$ | $La_2O_3$ | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| *Blk.-brown* | 32·75 | 0·98 | 11·45 | 17·21 | 3·77 | 2·22 | 3·64 | 3·46 | 4·64 | 7·95 | 11·95 | = 100·02 |
| *Red* | 38·40 | 0·94 | 15·65 | 19·97 | 3·52 | 1·93 | 4·19 | 4·42 | 3·50 | 3·60 | 13·97 | = 101·09 |

MUROMONTITE *Kerndt*, J. pr. Ch., **43**, 228, 1848. In grains. H. = 7. G. = 4·263. Luster vitreous or slightly greasy. Color black or greenish black. Apparently related to allanite, but containing much of the yttrium metals, also beryllium and but little aluminium or cerium. Analysis—Kerndt:

| $SiO_2$ | $Al_2O_3$ | $Y_2O_3$[a] | $Ce_2O_3$ | $La_2O_3$ | BeO | FeO | MnO | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$&loss | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 31·09 | 2·23 | 37·14 | 5·54 | 3·54 | 5·52 | 11·23 | 0·91 | 0·71 | 0·42 | 0·65 | 0·17 | 0·85 | = 100 |

[a] Yttrium earths.

From Mauersberg, near Marienberg, in the Saxon Erzgebirge. Named from a Latin rendering of Mauersberg.

BODENITE *Breith.*, Pogg., **62**, 273, 1844, *Kersten*, ib., **63**, 135, *Kerndt.*, J. pr. Ch., **43**, 219, 1848. Related to muromontite in composition, and in containing more yttrium than cerium, but has a larger percentage of alumina and lime, and no glucina, and is hydrous. Composition according to Kerndt:

| $SiO_2$ | $Al_2O_3$ | $Y_2O_3$[a] | $Ce_2O_3$ | $La_2O_3$ | FeO | MnO | CaO | MgO | $Na_2O_3$ | $K_2O$ | $H_2O$ | |

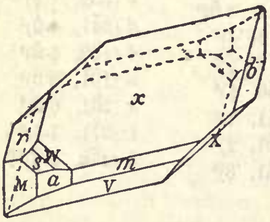
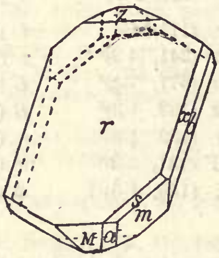
Crystals usually broad and acute-edged, but varied in habit; usually with *M* (1$\bar{1}$0) and *r* (1$\bar{1}$1) prominent, rarely *x* (111); also rarely prismatic ‖ $\dot{c}$ (f. 3). Faces in zone *maM*, also *Msx*, often striated ‖ their respective intersection-edges; also *r* usually striated ‖ edge *r*/*M*. Also massive, lamellar, lamellæ often curved; sometimes granular.

Cleavage: *b* distinct; also *c*, *w*; *r* interrupted; *M*, *y* in traces (Dx.). Fracture conchoidal. Brittle. H. = 6·5–7. G. = 3·271 Haid.; 3·294 but after fusion 2·812 Rg. Luster highly glassy. Color clove-brown, plum-blue, and pearl-gray; also honey-yellow, greenish yellow. Streak uncolored. Transparent to subtranslucent.

7.



8.



7, Franklin, N. J., Pfd. 8, Guadalcazar, Id.

Pleochroism strong: ⊥ *r* pale olive-green, giving with dichroscope olive-green and violet-blue; ⊥ edge *r*/*M* and ‖ *r* cinnamon-brown, giving cinnamon-brown and violet-blue. Exhibits idiophanous figures. Optically –. Ax. pl. and $Bx_a$ approximately ⊥ *x* (111). The trace of the ax. pl. inclined 40° to edge *x*/*M*, and 24° 40′ to edge *x*/*r*. Dispersion $\rho < v$; inclined and horizontal, very prominent. Axial angles somewhat variable, even in sections from same crystal, Dx.

$$\left.\begin{matrix} 2H_{a.r} = 87^\circ\ 30' \\ 2H_{a.r} = 86^\circ\ 33' \end{matrix}\right\} \beta_r = 1{\cdot}678 \ \therefore \left\{\begin{matrix} 2V_r = 74^\circ\ 17' \\ 2V_r = 73^\circ\ 32' \end{matrix}\right. \quad \left.\begin{matrix} 2H_{a.bl} = 87^\circ\ 47' \\ 2H_{a.bl} = 86^\circ\ 43' \end{matrix}\right\} \beta_{bl} = 1{\cdot}691 \ \therefore \left\{\begin{matrix} 2V_{bl} = 74^\circ\ 39' \\ 2V_{bl} = 73^\circ\ 49' \end{matrix}\right.$$

Also for sections I, very thin; II, rather thick.

I. $2H_{a.r} = 84^\circ\ 7'$ $2E_r = 157^\circ\ 51$ II. $2H_{a.r} = 82^\circ\ 15'$ $2E_r = 148^\circ\ 53'$

| Indices | α | β | γ | | 2V | 2E |

Pyroelectric, when heated to 120° or 130°, the analogous pole (Riess & Rose) at the solid angle *rxM′*; the antilogous pole at the angle *mr′M′* near plane *n*. Hankel finds on cooling the acute edges *r*/*m* positive; the faces *M* and the obtuse edges *r*/*m* negative.

**Comp.**—A boro-silicate of aluminium and calcium with varying amounts of iron and manganese. Exact composition doubtful; the formulas obtained by Rammelsberg and Whitfield are:

Rg., $HR_3BAl_2(SiO_4)_4$; Whitfield, $H_2R_4(BO)Al_3(SiO_4)_6$. R = Calcium chiefly, sometimes in large excess (anal. 4), again in smaller amount and manganese prominent (anal. 5–7); iron is present in small quantity, also magnesium and basic hydrogen.

**Anal.**—1, Rg., Zs G. Ges., **21**, 689, 1869. 2, 3, Whitfield, Am. J. Sc., **34**, 286, 1887. 4, Baumert, quoted by Luedecke, Zs. Nat. Halle, **42**, 1, 1889. 5–7, F. A. Genth, Am. J. Sc., **41**, 394, 396, 1891.

[a] ZnO, including 0·12 CuO. [b] ZnO, including 0·09 PbO, 0·11 CuO. [c] CuO.

**Pyr., etc.**—B.B. fuses readily with intumescence, imparts a pale green color to the O.F., and fuses at 2 to a dark green to black glass; with borax in O.F. gives an amethystine bead (manganese), which in R.F. becomes yellow (iron). Fused with a mixture of bisulphate of potash and fluor on the platinum loop colors the flame green (boric acid). Not decomposed by acids, but when previously ignited, gelatinizes with hydrochloric acid.

**Obs.**—Axinite occurs in implanted glassy clove-brown crystals, at St. Cristophe, near Bourg d'Oisans in Dauphiné, with albite, prehnite, and quartz. In the Harz at Andreasberg, Treseburg, also in the Radauthal; in granite at Striegau, Silesia; on Mt. Monzoni, in Tyrol, with brown garnet and calcite forming a vein in diabase; Piz Valatscha, the northern spur of Mt. Skopi south of Dissentis in Eastern Switzerland; Poloma, Hungary; Baveno, Italy; Elba; at the silver mines of Kongsberg, Norway, in small crystals; with hornblende or magnetic iron in Nordmark, Sweden; L. Onega, Russia, and near Miask in the Ural; in Cornwall, of a dark color, at the Botallack mine near St. Just, where it also occurs massive, forming a peculiar kind of rock with garnet and tourmaline; at Trewellard, at Carn Silver near Lamorran creek, and at Boscawen Cliffs in St. Burien; in Devonshire, at Brent Tor, 4 m. north of Tavistock; at Thum near Ehrenfriedersdorf in Saxony. It occurs with gray cobalt near Coquimbo, Chili, at the mine La Buitro. At Guadalcazar, Mexico, in minute brownish or greenish crystals embedded in feldspar, which is in part changed to kaolinite.

In the U. S., at Phippsburg, Maine, with yellow garnet and vesuvianite; at Wales, Maine; at Cold Spring, N. Y.; Franklin Furnace, N. J., in honey-yellow crystals and laminated forms with rhodonite, polyadelphite, barite; at Bethlehem, Pa., with amphibole. Rare in Northumberland Co., Nova Scotia, on McKay's brook, a branch of N.E. Mirimichi river.

Named from *ἀξίνη, an axe*, in allusion to the form of the crystals. The name *yanolite* is of earlier date; but it means *violet-stone*, and violet is not a characteristic color of the mineral.

**Alt.**—Crystals altered to chlorite occur on Dartmoor in Devonshire, England.

**Ref.**—[1] Pogg., **128**, 20, 227, 1866 (Rath's axes calculated for Naumann's position are entirely wrong). The position taken is that of Naumann; see Frazier (Am. J. Sc., **24**, 442, 1882) for a table giving the symbols of the planes in the positions of Neumann and Miller, Rath, Des Cloizeaux, Schrauf, and Frazier; the last two chosen to show relation to titanite and datolite respectively. See also Gdt., Index, **1**, 271, 1886, who gives transformation-equations; Solly, Min. Mag., **6**, 203, 1886; Hintze, Min., **2**, 487, 1891.

4, Jordansmühl, Beutell.

*mm‴* = 80° 4′
*pp′* = 43° 17′
*vv′* = 52° 42′
*nn′* = 89° 28′
*oo′* = 146° 34′
*oo‴* = *33° 26′
*cr* = 59° 54′
*cs* = 79° 4′
*rr′* = 82° 58′
*rr‴* = 67° 38′
*ss′* = 97° 29′
*ss″* = 78° 20′

Distinct individual crystals rare; usually tabular ‖ *c;* sometimes prismatic; again acute pyramidal. Faces *c* striated ‖ edge *a/c; b* rough and uneven; *m* smooth and brilliant, also striated ‖ edge *m/c.* Commonly in groups of tabular crystals, united by *c* making broken forms, often barrel-shaped. Reniform, globular, and stalactitic with a crystalline surface. Structure imperfectly columnar or lamellar, strongly coherent; also compact granular or impalpable.

Cleavage: *c* distinct. Fracture uneven. Brittle. H. = 6–6·5. G. = 2·80–2·95. Luster vitreous; *c* weak pearly. Color light green, oil-green, passing into white and gray; often fading on exposure. Subtransparent to translucent. Streak uncolored. Pyroelectric, with polarity central, the analogous poles at the center of the base and the antilogous at the extremities of the brachydiagonal[4].

Optically +. Double refraction strong. Ax. pl. usually ‖ *b,* dispersion $\rho > v$ or $\rho < v$, weak; sometimes (Farmington) ‖ *a,* dispersion strong $\rho > v$. Bx ⊥ *c.* Index $\beta_y = 1{\cdot}626$. Axial angles variable, Dx.:

| | | | |
|---|---|---|---|
| Dauphiné | $2H_r = 74° \, 29'$ to $76° \, 7'$ | ∴ | $2E_r = 124° \, 54'$ to $129° \, 9'$ |
| " | $2H_r = 75° \, 22'$ to $75° \, 52'$ | ∴ | $2E_r = 127° \, 9'$ to $128° \, 28'$ |
| Pyrenees | $2H_r = 73° \, 43'$ to $74° \, 42'$ | ∴ | $2E_r = 122° \, 59'$ to $125° \, 27'$ |

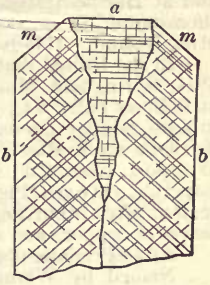
Also for homogeneous crystals, Beutell:

$2H_{a\cdot r} = 77° \, 41'$ $2H_{a\cdot y} = 77° \, 44'$ $2H_{a\cdot bl} = 77° \, 53'$ ∴ $2E_y = 135° \, 26'$ $2V_y = 69° \, 22'$

Ratschinges $\alpha_y = 1{\cdot}616$ $\beta_y = 1{\cdot}626$ $\gamma_r = 1{\cdot}649$ Lévy-Lcx.

The grouping in the common aggregated forms is often highly complex with consequent wide variation in the optical characters (cf. Dx., Mld., Emerson, Beutell)[5]; crossed dispersion, otherwise characteristic of the monoclinic system is often observed. For example, a section ∥ *c* (f. 5) of a variety from Farmington was divided (Mld.) into two parts: (1) a central wedge-shaped portion with lamellæ chiefly ∥ *a*, also ⊥ *a*, with parallel extinction; optically +; ax. pl. usually ∥ *a*, also ⊥ *a*; angle variable but usually small and becoming 0°. (2) Also lateral sectors (see fig.) with lamellæ chiefly ∥ *m* and less prominent nearly ⊥ *m* (110 and $1\bar{1}0$), the angle included being 82°–83°; these lamellæ show no definite extinction; the axial figure is distorted, crossed dispersion is visible; ax. pl. inclined about 48° to the normal to *a* for red and about 58° for blue.

5.



The peculiarities of the wedge-shaped portion are explained by the presence of two systems of thin layers superimposed normal respectively to the + and − bisectrix; in the lateral sectors there is an intergrowth of systems of lamellæ having a common base but whose axes of elasticity are inclined 60° to each other, thus producing rotatory polarization, analogous to that produced by mica laminæ crossed at angles of 60°.

**Var.**—Usual in firm and hard incrusting masses, externally globular or mammillary, the surface made up often of grouped crystals more or less imperfect, but sometimes smooth.

*Coupholite* is in cavernous masses, made of small, thin, fragile laminæ or scales; the original was from the peak of Ereslids, near Barèges, in the Pyrenees; also reported from the Col du Bonhomme, at the foot of Mt. Blanc. Named from κοῦφος, *tender*. *Edelite*, or *Ædelite*, is prehnite from Ædelfors, Sweden. *Jacksonite*, or "*anhydrous prehnite*," of Whitney is ordinary prehnite, from Keweenaw Pt. and Isle Royale; it contains 4 to 5 p. c. water (Jackson and Brush); that examined by Whitney may have been from a specimen previously calcined with associated ores.

**Comp.**—An acid orthosilicate, $H_2Ca_2Al_2Si_3O_{12}$ = Silica 43·7, alumina 24·8, lime 27·1, water 4·4 = 100.

Prehnite is sometimes classed with the zeolites, with which it is often associated; the water here, however, has been shown to go off only at a red heat (Rg.), and hence plays a different part. Doelter (Jb. Min., **2**, 137, 1890) calls attention to a similarity in composition to friedelite, p. 465.

**Pyr., etc.**—In the closed tube yields water. B.B. fuses at 2 with intumescence to a blebby enamel-like glass. Decomposed slowly by hydrochloric acid without gelatinizing; after fusion dissolves readily with gelatinization. *Coupholite*, which often contains organic matter, blackens and emits a burnt odor.

**Obs.**—Occurs chiefly in basic eruptive rocks, basalt, diabase, etc., as a secondary mineral in veins and cavities, often associated with some of the zeolites, also datolite, pectolite, calcite, but commonly one of the first formed of the series; also less often in granite, gneiss, syenite, and then frequently associated with epidote; sometimes associated with native copper, as in the L. Superior region.

At St. Christophe and l'Armentières, near Bourg d'Oisans in Dauphiné, associated with axinite and epidote; at Ratschinges in Tyrol, in the Fassathal, and near Campitello; in Salzburg; the Ala valley in Piedmont; the Saualpe in Carinthia; Joachimsthal in Bohemia; in Nassau, at Oberscheld and Uckersdorf; near Freiburg in Baden on the Rosskopf; Schwarzenberg in Saxony, in the Harz, near Andreasberg, with datolite, and near Harzburg in the Radauthal; in granite at

Striegau, Silesia, also at Jordansmühl; Arendal, Norway; Ædelfors in Sweden (*edelite*); Upsala, Sweden, in rifts in hornblendic granite, the decomposition of the hornblende having afforded the lime, and of the mica, the alumina (Paijkull); at Friskie Hall and Campsie in Dumbartonshire, and at Hartfield Moss, in Renfrewshire, in veins traversing trap, associated with analcite and thomsonite; also at Corstorphine Hill, the Castle and Salisbury Craig, near Edinburgh; Mourne Mts., Ireland. Handsome polished slabs of this mineral have been cut from masses from China.

In the United States, finely crystallized at Farmington, Woodbury, and Middletown, Conn., West Springfield, Mass., and Paterson and Bergen Hill, N. J.; in small quantities in gneiss, at Bellows Falls, Vt.; in syenite, at Somerville, Mass.; Milk Row quarry, Somerville, often in minute tabular crystals, with chabazite, also with epidote; also at Palmer (Three Rivers) and Turner's Falls, Mass., on the Connecticut, in trap, and at Perry, above Loring's Cove, Maine; at Westport, Essex Co., N. Y. (*chiltonite* Emmons), on a quartzose rock; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac; in large veins in the Lake Superior copper region, often occurring as the veinstone of the native copper, sometimes including strings or leaves of copper; and at times in radiated nodules disseminated through the copper.

**Alt.**—Prehnite occurs altered to green earth and feldspar.

Named by Werner in 1790 after Col. Prehn, who first found the mineral at the Cape of Good Hope. Sage had called it (1777) *chrysolite*, and Romé de Lisle had referred it (1783) to the group of *schorl*.

**Ref.**—[1] Harzburg, Jb. Min., 314, 1870. [2] See Mlr., Min., p. 415, 1752; Dx., Min., **1**, 430, 1862. [3] Beutell, Jordansmühl, l. c.; cf. also Schubert, l. c., who, however, gives neither axes nor angles. [4] Riess and Rose, Pogg., **59**, 382, 1843. See also Hankel, Wied. Ann., **6**, 55, 1879. [5] On the methods of grouping and consequent optical anomalies, cf. Dx., Bull. Soc. Min., **5**, 58, 125, 1882; Mld., ib., p. 195; Wyrouboff, ib., p. 272; Emerson, Am. J. Sc., **24**, 270, 1882.

UIGITE *Heddle*, Ed. N. Phil. J., **4**, 162, 1856, Min. Mag., **5**, 26, 1882. In radiated sheafy clusters of plates, in nests in the amygdaloid of Uig, Isle of Skye, along with analcite and faroelite. H. = 5·5; G. = 2·284; luster pearly; color white, slightly yellowish. Composition, according to Heddle: $SiO_2$ 45·98, $Al_2O_3$ 21·93, CaO 16·15, $Na_2O$ 4·69, $H_2O$ 11·25. B.B. fuses readily and quietly to an opaque enamel, which is not frothy. It appears to be near prehnite in structure, and needs further investigation.

PREHNITOID. Prenitoide *Bechi*, Boll. Com. Geol., 66, 1870; Acc. Linc. Trans., **3**, 114, 1879. An impure massive prehnite filling crevices in the gabbro of Monte Catini, Tuscany. An analysis of a crystalline variety gave: $SiO_2$ 42·30, $CO_2$ 2·85, $B_2O_3$ 0·33, $Al_2O_3$ 22·06, $Fe_2O_3$ 0·70, CaO 28 86, MgO *tr.*, $H_2O$ 2·98, N 0·19 = 100·27. Cf. Corsi, l. c. This name belongs properly to a kind of scapolite, p. 471.

**412. HARSTIGITE.** Harstigit *G. Flink*, Ak. H. Stockh., Bihang, **12** (2), No. 2, 59, 1886.

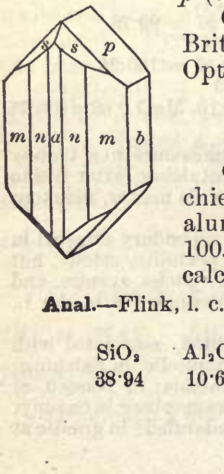
Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·71479 : 1 : 1·01495$ Flink[1].

$100 \wedge 110 = 35° 33\frac{1}{2}'$, $001 \wedge 101 = 54° 50\frac{2}{3}'$, $001 \wedge 011 = 45° 25\frac{1}{2}'$.

**Forms:** *a* (100, *i*-ī), *b* (010, *i*-ĭ); *n* (210, *i*-2̄), *m* (110, *I*); *p* (011, 1-ĭ); *s* (122, 1-2̆).

Angles, *an* = *19° 40′, *nn′* = 39° 20′, *mm‴* = 71° 7′, *pp′* = *90° 51′, *ss′* = 52° 58′, *ss″* = 102° 10′, *ss‴* = 79° 14′.

In small crystals, prismatic ∥ $\dot{c}$, with *b* prominent and terminated by the dome *p* (011) with *s* (122) small.



Cleavage not observed. Fracture small conchoidal to splintery. Brittle. H. = 5·5. G. = 3·049. Luster vitreous. Colorless. Optically +. Ax. pl. ∥ *b*. Bx ⊥ *a*. Axial angles, Flink:

$2H_{a.r} = 57° 50'$ $2H_{a.y} = 57° 56'$ $2H_{a.gr} = 58° 8'$ $2V_y = 90° 27'$

Also $\alpha_y = 1·6782$ $\gamma_y = 1·68308$ Na Ramsay[2].

**Comp.**—An acid orthosilicate of manganese and calcium chiefly, formula probably $H_7(Ca,Mn)_{12}Al_3Si_{10}O_{40}$ = Silica 39·2, alumina 10·0, manganese protoxide 13·9, lime 32·8, water 4·1 = 100. Here Mn : Ca = 3 : 1. Magnesium replaces part of the calcium.

**Anal.**—Flink, l. c.:

| $SiO_2$ | $Al_2O_3$ | MnO | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 38·94 | 10·61 | 12·81[a] | 29·23 | 3·27 | 0·35 | 0·71 | 3·97 = 99·89 |

[a] FeO *tr.*

**Pyr., etc.**—Reacts for manganese with the fluxes. Gives off water on strong ignition and turns black. The ignited powder dissolves easily in hydrochloric acid with evolution of chlorine.

**Obs.**—Occurs with yellowish red or brown garnets, in rhombic dodecahedrons, and crystals of pale red rhodonite at the Harstig mine, near Pajsberg, in Wermland, Sweden. These associated species occur lining the sides of a narrow vein which was ~~filled in~~ with calcite as a later deposit.

**Ref.**—[1] l. c. [2] Zs. Kr., **12**, 220, 1886.

---

## 413. CUSPIDINE. *Scacchi*, Rendiconto R. Accad. Napoli, October 14, 1876; Zs. Kr., **1**, 398, 1877.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}7243 : 1 : 1{\cdot}9342$. $\beta = 89° 22' = 001 \wedge 100$ Rath[1].

$100 \wedge 110 = 35° 54\frac{5}{6}'$, $001 \wedge 101 = {*}68° 55'$, $001 \wedge 011 = 62° 39\frac{1}{2}'$.

**Forms**[1]:

$\nu$ ($\bar{1}$11, 1)
$t$ (211, $-$ 2-$\bar{2}$)
$\mu$ ($\bar{4}$32, 2-$\frac{4}{3}$)

$q$ (233, $-$ 1-$\frac{3}{2}$)
$s$ ($\bar{1}$21, 2-$\grave{2}$)
$r$ (872, $-$ 4-$\frac{8}{7}$)?

$mm''' = 71° 50'$
$ch = 41° 23\frac{1}{2}'$
$cf = 70° 1\frac{1}{2}'$
$kk' = 51° 36\frac{1}{2}'$

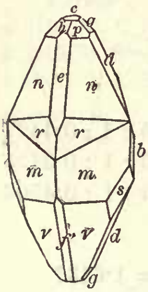
$gg' = 88° 5'$
$dd' = 125° 19'$
$cp = 47° 25'$
$cn = 72° 39\frac{1}{2}'$

$c\pi = 47° 59'$
$c\nu = 73° 36'$
$pp' = 51° 11'$
$nn' = 68° 6'$

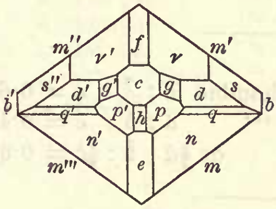
$en = {*}34° 3'$
$\pi\pi' = 51° 40\frac{1}{2}'$
$\nu\nu' = 68° 29'$
$ss' = 107° 24'$

In minute spear-shaped crystals, aparently orthorhombic, but proved to be usually contact-twins with tw. pl. $a$, giving $c\underline{c} = {*}1° 16'$.

1.



2.



Monte Somma, Rath.

Cleavage: $c$ very distinct. Fracture uneven. Brittle. H. = 5–6. G. = 2·853–2·860. Luster vitreous. Color pale rose-red.

Ax. pl. ∥ $b$. $Bx_{a.y} \wedge \grave{c} = -5° 30'$. $2E_y = 110°$. Dispersion of the axis, also inclined very marked. Groth.

**Comp.**—Contains silica, lime, fluorine, and from alteration carbon dioxide. Formula doubtful.

A partial analysis by E. Fisher gave: CaO 59·8 (again 59·9), $Fe_2O_3$ 1·18, $CO_2$ 1·2; also F 9 to 10 p. c. Zs. Kr., 8, 39, 1883. Perhaps $Ca_2SiO_4$ with $CaF_2$.

**Pyr.**—B.B. fusible with difficulty. Readily soluble in nitric acid.

**Obs.**—From Vesuvius, in ejected masses from the tufa of Monte Somma. It occurs only very sparingly; in part in cavities with augite, hornblende, biotite, calcite, also a brown garnet and crystals of davyne; in part also embedded in a granular rock-like mass. The crystals are usually more or less altered on the surface, becoming covered with a shell of calcium carbonate.

Scacchi suggested as the probable composition $Ca_2SiO_4$ with about one-third of the lime replaced by $CaF_2$ and Fischer's trials, so far as they are conclusive, confirm this. The determination of the exact composition requires a more complete analysis, however, and it may prove not to belong to the orthosilicates with which it is provisionally placed.

Named from cuspis, *a spear*, in allusion to the characteristic form of the crystals.

**Ref.**—[1] Zs. Kr., **8**, 38, 1883, Ber. nied. Ges., 122, 1882; Groth, Zs. Kr., **8**, 43, 1888.

## IV. Subsilicates.

The species here included are basic salts, for the most part to be referred either to the metasilicates or orthosilicates, like many basic compounds already included in the preceding pages. Until their constitution is definitely settled, however, they are more conveniently grouped by themselves as SUBSILICATES. It may be noted that those species having an oxygen ratio of silicon to bases of 2 : 3, like topaz, andalusite, sillimanite, datolite, etc. (pp. 492–502 *et seq.*), also calamine, carpholite, and perhaps tourmaline, are sometimes regarded as salts of the hypothetical parasilicic acid, $H_8SiO_6$.

---

### Division I. Oxygen Ratio for Si : R = 4 : 5. Formula $R_5Si_2O_9$.

### Humite Group.

| | | | |
|---|---|---|---|
| 414. **Humite** | $H_2(Mg,Fe)_{19}Si_8O_{34}F_4$? | Orthorhombic<br>or | $\breve{a} : \bar{b} : \acute{c} = 0{\cdot}9258 : 1 : 4{\cdot}0764$<br>$\bar{b} : \breve{a} : \acute{c} = 1{\cdot}0802 : 1 : 4{\cdot}4033$ |
| 415. **Chondrodite** | | Monoclinic | $\grave{a} : \overset{\mid}{b} : \acute{c} = 1{\cdot}0863 : 1 : 3{\cdot}1447$<br>$\beta = 90°$ |

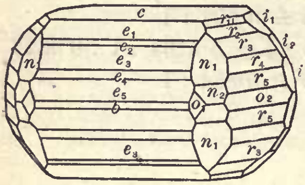
Twins[5]: tw. pl. (1) $e_y$ (017), with $c\underline{c}$ = 60° 26′ and 119° 34′; also (2) $e_x$ (037), with $c\underline{c}$ = 120° 25½′ and 59° 34½′; usually penetration-twins; sometimes also trillings. These two laws give nearly the same twinning angles. Crystals small and highly modified, usually elongated ‖ $\breve{a}$, or ‖ $\dot{c}$. Planes in zone *c e b* often horizontally striated.

4.



Cleavage: *c* distinct. Fracture subconchoidal to uneven. Brittle. H. = 6–6·5. G. = 3·1–3·2. Luster vitreous to resinous. Color white, yellowish white, light yellow, honey-yellow, chestnut-brown. Sometimes pleochroic.

Optically +. Double refraction strong. Ax. pl. ‖ *c*. $Bx_a \perp a$. Dispersion weak. $2H_{a.r}$ = 78° 18′–79°, Dx.

**Comp., Pyr., Obs., etc.**—See pp. 539, 540.

**Ref.**—[1] Mte. Somma, l. c. The position taken in this and the following cases is that of Scacchi and vom Rath, which seems to show the relations most simply. The letters are those of Scacchi, except for the pinacoids and unit prism. The lateral axes for the three species of this group are the same or nearly so; the vertical axes are closely in the ratio of 7 : 5 : 9 respectively. Cf. p. 534.

In the axial ratio taken by J. D. D. (Min., p. 362, 1868); also E. S. D. (Conn. Acad., **3**, 67, 1875, Am. J. Sc., **10**, 89, 1875), and H. Sjögren (Zs. Kr., **7**, 344, 1882), the vertical axes are divided by 3, 2 and 4 respectively. The axes assumed by Rath (Pogg. Erg., **5**, 324, 1870) are unsatisfactory, being deduced from measurements of clinohumite (Humite, Type III.). The following are the axial ratios (with $\breve{a}$ = 1) deduced by the authors named:

| | $\breve{a}$ : $\bar{b}$ : $\dot{c}$ | |
|---|---|---|
| Mte. Somma | 1 : 1·0802 : 4·4033 | A. Scc. |
| " " | 1 : 1·0803 : 4·4013 | Rath |
| Ladu mine, Sweden | 1 : 1·1096 : 4·3948 | H. Sj. |

[2] A. Scc., l. c. [3] Rath, l. c., p. 325. [4] E. Scc., Rend. Acc. Napoli, Dec., 1883. See Rath, l. c., p. 330, for a description of the occurring twins.

**415. CHONDRODITE.** Des Cloizeaux, Phil. Mag., **2**, 286, 1876, **3**, 357, 1877; Jb. Min., 641, 1876, 500, 1877. Humite, Type II., *A. Scacchi*, Accad. Sc. Napoli, **6**, 1851.

Monoclinic. Axes $\grave{a} : \bar{b} : \dot{c}$ = 1·08630 : 1 : 3·14472; β = 90° = 001 ∧ 100 E. S. Dana[1].

100 ∧ 110 = 47° 22′ 7″, 001 ∧ 101 = 70° 56′ 36″, 001 ∧ 011 = 72° 21′ 35″.

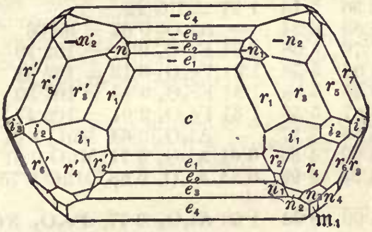
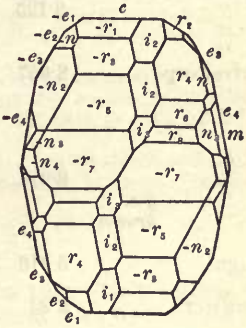
Twins: (1) tw. pl. $-e_3$ (103) common, less so (2) $+e_3$ (103); often cruciform twins and with both laws combined. (3) $c$ (f. 2); often as polysynthetic twinning lamellæ, as with chondrodite; these lamellæ present also in twins according to the other laws. Also massive.

Cleavage: $c$ sometimes distinct. Fracture subconchoidal. Brittle. H. = 6–6·5. G. = 3·1–3·2. Luster vitreous. Color white, yellowish or grayish white, more commonly light to dark brown, reddish brown, yellow, dark honey-yellow, also red.

3.



4.



3, 4. Mte. Somma, Rath.

Optically +. Ax. pl. and $Bx_a \perp b$. $Bx_o \wedge \dot{c} = \mathfrak{a} \wedge \dot{c} = +11°$ Dx.; $Bx_{o.y} \wedge \dot{c} = +12° 28'$ Klein, Mte. Somma[6]. $Bx_o \wedge \dot{c} = 7\frac{1}{2}°$ approx., Brewster[6]. Dispersion weak. Axial angles:

Mte. Somma $2H_{a.y} = 84° 40'$ to $85° 15'$ Klein
" *white* $2H_{.r} = 84° 38'$ to $85° 4'$ *yellow* $= 86° 40'$ to $87° 14'$ Dx.

**Comp., Pyr., Obs., etc.**—See below.
**Ref.**—[1] Mte. Somma, Pogg., Erg., **5**, p. 373, 1870. Other axial ratios are:

| | $\dot{a} : \bar{b} : \dot{c}$ | |
|---|---|---|
| Mte. Somma | 1·0808 : 1 : 5·6669 | A. Scc. |
| Brewster | 1·0863 : 1 : 5·6605 | E. S. D. |

Dx. makes $A = 001$, $e_4 = 100$, $r_4 = 111$, etc.

**Pyr., etc.**—B.B. infusible; some varieties blacken and then burn white. Fused with potassium bisulphate in the closed tube gives a reaction for fluorine. With the fluxes a reaction for iron. Gelatinizes with acids. Heated with sulphuric acid gives off silicon fluoride.

**Obs.**—Humite, chondrodite, and clinohumite (humite, Types I, II, III, Scc.) all occur at Vesuvius in the ejected masses both of limestone or feldspathic type found on Monte Somma. They are associated with chrysolite, biotite, pyroxene, magnetite, spinel, vesuvianite, calcite, etc.; also less often with sanidine, meionite, nephelite. Of the three species, humite is the rarest and clinohumite of most frequent occurrence. They seldom all occur together in the same mass (though this has in one case been noted by E. Scacchi), and only rarely two of the species (as humite and clinohumite) appear together. Occasionally clinohumite interpenetrates crystals of humite, and parallel intergrowths with chrysolite have also been observed.

*Humite* has also been identified at the Ladu mine near Filipstad, Wermland, Sweden, with magnetite in crystalline limestone; it is in part altered to serpentine. In crystalline limestone with clinohumite in the Llanos de Juanar, Serrania de Ronda, Andalusia (Lévy-Lcx., Bull. Soc. Min., **9**, 81, 1886). Also in large coarse, partly altered, crystals at the Tilly Foster iron-mine at Brewster, N. Y.

*Chondrodite* at Mte. Somma, as above noted; at Pargas, Finland, of honey-yellow color in limestone, also at other points in Finland; at Kafveltorp, Nya-Kopparberg, Sweden, associated with chalcopyrite, galena, sphalerite. In granular limestone of Strehlen, Silesia. Abundantly at Brewster, N. Y., at the Tilly Foster magnetic iron mine in deep garnet-red crystals of great beauty and variety of form. Also probably at numerous points where the occurrence of "chondrodite" has been reported.

*Clinohumite* occurs at Mte. Somma as noted above; in Andalusia, Llanos de Juanar, embedded in limestone as polysynthetic lamellæ in parallel intergrowth with humite (Lévy-Lcx., l. c.); in crystalline limestone near L. Baikal in East Siberia; at Brewster, N. Y., in rare but highly modified crystals.

Numerous other localities of "chondrodite" have been noted, chiefly in crystalline limestone; most of them are probably to be referred to the species chondrodite, but the identity in many cases is yet to be proved. Some of the foreign localities are: Strehlen in Silesia; Boden near Marienberg, Saxony; Loch Ness, Scotland; Achmatovsk in the Ural; with spinel in the limestone of Huerta and Sierra de Cordoba, Argentine Republic; Heteroland, S. Africa; with spinel in crystalline limestone in Spitzbergen.

At Brewster large quantities of massive "chondrodite" occur associated with magnetite, enstatite, ripidolite, and from its extensive alteration serpentine has been formed on a large scale.

The granular mineral is common in limestone in Sussex Co., N. J. (chondrodite, Lévy & Lex), and Orange Co., N. Y., associated with spinel, and occasionally with pyroxene and corundum. In *N. Jersey*, at Bryam, orange and straw-colored chondrodite, and also a variety nearly black, occurs with spinel; at Sparta, a fine locality of honey-yellow chondrodite; a mile to the north of Sparta the best locality of this mineral in N. J.; at Vernon, Lockwood, and Franklin. In *N. York*, in Orange Co., in Warwick, Monroe, Cornwall, near Greenwood Furnace, and at Two Ponds, and elsewhere; near Edenville in fine specimens on the land of Mr. Houston; also sparingly in Rossie, on the bank of Laidlaw Lake. In *Mass.*, at Chelmsford, with scapolite; at South Lee, in limestone. In *Penn.*, near Chaddsford, in Harvy's quarry, of yellow and orange colors, abundant. In *Canada*, in limestone at St. Crosby, St. Jerome, St. Adèle, Grenville, etc., abundant.

The name chondrodite is from *χόνδρος*, *a grain*, alluding to the granular structure. *Brucite* was given by Col. Gibbs after Dr. Bruce (1777–1818), editor of the American Mineralogical Journal; *Maclureite* by Seybert, after Wm. Maclure (1763–1840). Humite is from Sir Abraham Hume.

**Alt.**—Chondrodite altered to serpentine occurs at Sparta, N. J., with spinel and mica; also at Brewster, N. Y., where it is extensively altered, yielding serpentine in large quantities, see J. D. D., Am. J. Sc., **8**, 371, 1874.

**Pyr., etc.**—B.B. fuses quietly at 2·5 to a black magnetic bead. With the fluxes reacts for iron. Some varieties give also a reaction for manganese. Gelatinizes with hydrochloric acid.

**Obs.**—First found on the Rio la Marina, and at Capo Calamita, on Elba, by M. Lelièvre, in 1802, where it occurs in large solitary crystals, and aggregated crystallizations in dolomite with pyroxene, etc. Also found near Andreasberg in the Harz; between Herborn and Herbornseelbach in Nassau; Kupferberg, Silesia; at the mine of Temperino in Tuscany, granular, in limestone with actinolite; on Mt. Mulatto near Predazzo, Tyrol, in granite; at Schneeberg in Saxony; Fossum near Skeen in Norway; Thyrill, Iceland; in the sodalite-syenite of the Kangerdluarsuk fiord in South Greenland (cf. Lorenzen, Min. Mag., **5**, 70, 1882).

Reported as formerly found at Cumberland, R. I., in slender black or brownish black crystals, traversing quartz along with magnetite and hornblende; also at Milk Row quarry, Somerville, Mass.

Named *Ilvaite* from the Latin name of the island (Elba) on which it was found; *Lievrite* after its discoverer; *Yenite* (should have been Jenite) in commemoration of the battle of Jena, in 1806. The Germans, and later the French, have rightly rejected the name *yenite*, on the ground that commemorations of political hostility or triumph are opposed to the spirit of science. Des Cloizeaux adopts *Ilvaite*.

*Wehrlite* of Kobell has been referred to lievrite, as suggested by Zipser. It is massive granular. H. = 6–6·5 G. = 3 90. Analysis by Wehrle, $SiO_2$ 34·60, $Fe_2O_3$ 42·38, $Mn_2O_3$ 0·28, $Al_2O_3$ 0·12, FeO 15·78, CaO 5 84, $H_2O$ 1·00 = 100. B.B. fuses with difficulty on the edges. Imperfectly soluble in hydrochloric acid. From Szurraskö, Hungary. Some of the specimens so called have proved to be highly heterogeneous, cf. Szabó, Zeph., Min. Lex. Öest., **2**, 343, 1873.

**Ref.**—[1] Ann. Mines, **8**, 402, 1855, Min., **1**, 217, 1862. Other axial ratios deduced by Lorenzen and by Flink (ref. below) are:

Greenland $\breve{a} : \bar{b} : \grave{c}$ = 0·67437 : 1 : 0·44845 Lorenzen
Iceland $\breve{a} : \bar{b} : \grave{c}$ = 0·66195 : 1 : 0·43897 Flink

On the relation in form and composition between ilvaite and humite, see Websky, Ber. Ak. Berlin, 201, 1876.

Lévy-Lcx. give: Ax. pl. ‖ *b*. Bx ⊥ *c*. Pleochroism: 𝔠 pale yellow, 𝔟 gold-yellow, 𝔞 deep brownish yellow.

**Comp.**—A vanadio-silicate of aluminium and manganese, composition uncertain; probable empirical formula $H_5Mn_4Al_4VSi_4O_{23}$ or $5H_2O.8MnO.4Al_2O_3.V_2O_5.8SiO_2$ = Silica 27·8, vanadium pentoxide 10·6, alumina 23·6, manganese protoxide 32·8, water 5·2 = 100.

Arsenic replaces the vanadium in varying amounts, but probably from alteration (Lsx.); magnesium and calcium replace part of the manganese, also ferric iron the aluminium in small amount.

**Anal.**—1, Lasaulx and Bettendorff, Pogg., **149**, 245, 1873. 2, 3, Bettendorff, ib., **160**, 126, 1877. 4, Pisani, C. R., **77**, 329, 1873, also an earlier one, ib., **75**, 1542, 1872, giving 8·71 p. c. $V_2O_5$ and no $As_2O_5$.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | MgO | CaO | $V_2O_5$ | $As_2O_5$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. *Dark brown* | 3·620 | $\frac{2}{2}$ 29·74[a] | 23·50 | 1·95 | 25·95 | 3·42 | 2·05 | 9·14 | — | 4·04 | CuO,$P_2O_5$ [*tr.* = 99·79 |
| 2. *Brown, transp.* | 3·643 | 27·84 | 24·22 | | 26·70 | 3·01 | 2·17 | 9 20 | 2·76 | 5·01 | = 100·91 |
| 3. *Yellow, opaque* | 3·656 | 27·50 | 22·76 | 1·15 | 30·61 | 1·38 | 1·83 | 0·53 | 9·33 | 5·13 | CuO 0·17= [100·39 |

[a] Probably contains free quartz. [b] Ign.

Other arsenic determinations gave Bettendorff: 1·83, 2·31, 2·53, 2·98, 6·64 $As_2O_5$; the color grows lighter with the increase in arsenic.

**Pyr., etc.**—B.B. easily fusible with intumescence to a black glass. With borax gives a manganese bead. The water can only be driven off at a strong red heat. Not attacked by hydrochloric and nitric acids, and only feebly attacked by sulphuric acid.

**Obs.**—Found at Salm Chateau near Ottrez in the Ardennes, Belgium, in quartz veins in the Ardennes schists. It is usually embedded in the quartz (containing particles of pyrolusite) and associated with a reddish white crystalline aggregate of albite.

Lasaulx first noticed this mineral under the name of *mangandisthen*, in consequence of a supposed resemblance to cyanite. This, as Pisani urges, is on several accounts an objectionable name, and is naturally superseded by the name *ardennite*, which too has the right of priority over *dewalquite*.

The name ardennite refers to the locality; dewalquite was given for the Belgian geologist, Prof. G. Dewalque.

**Ref.**—[1] Pogg., **147**, 247, 1873.

**419. LÅNGBANITE.** *G. Flink*, Zs. Kr., **13**, 1, 1887, Öfv. Ak. Stockh., Bihang, **13** (2), No. 7, 91, 1888. Longbanite.

Hexagonal. Axis $\dot{c}$ = 1·6437; 0001 ∧ $10\bar{1}1$ = *62° 13′ Flink[1].

**Forms:**

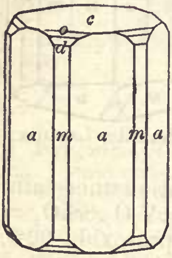
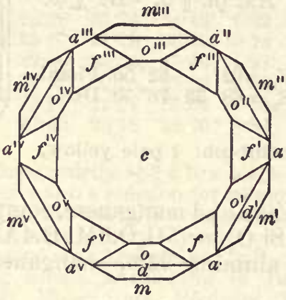
1.



2.



Figs. 1, 2, Långban, Flink.

Crystals hexagonal in habit, long or short prismatic; faces *a* prominent and vertically striated; *m* small and bright.

Cleavage none. Fracture conchoidal. Brittle. H. = 6·5. G. = 4·918. Luster metallic, brilliant. Color iron-black. Powder dark reddish brown. Opaque.

**Comp.**—Manganese silicate with ferrous antimonate; formula doubtful. Flink calculates $37Mn_6SiO_7.10Fe_3Sb_2O_8$. The state of oxidation of the metals present is not definitely settled.

**Anal.**—Flink, l. c.

$SiO_2$ 10·88 $Sb_2O_5$ 15·42 MnO 64·00 FeO 10·32 = 100·62

**Pyr.**—B.B. infusible, but becomes dull on the surface. On charcoal gives a faint white sublimate, and with salt of phosphorus a silica skeleton. Fused with soda and saltpeter gives a deep green mass. Difficultly soluble in hydrochloric acid without evolution of chlorine.

**Obs.**—Occurs sparingly at Långban, Wermland, Sweden, with schefferite in granular crystalline limestone, also associated with richterite, braunite, magnetite, hausmannite. Probably also with rhodonite at the Sjö mines, Gryhytte parish, Örebro, Sweden (Igelström).

**Ref.**—[1] L. c., and Zs. Kr., **15**, 93, 1888. See further p. 1039.

---

## Kentrolite Group.

**420. KENTROLITE.** *A. Damour* and *G. vom Rath*, Zs. Kr, **5**, 32, 1880.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·6334 : 1 : 0·8830 Rath.
100 ∧ 110 = 32° 21′, 001 ∧ 101 = 54° 20⅚′, 001 ∧ 011 = 41° 26⅔′.

Forms: *b* (010, *i-ĭ*); *m* (110, *I*); *o* (111, 1).

Angles. *mm′′′* = *64° 42′, *oo′* = 92° 31′, *oo′′* = 117° 34′, *oo′′′* = *54° 28′, *om* = 31° 13′.

Crystals minute, prismatic in habit terminated by the pyramid *o* (111); often grouped in sheaf-like forms resembling stilbite. Faces rather rough, the prismatic horizontally striated. Also massive.

Cleavage: *m* distinct. Fracture uneven. Brittle. H. = 5. G. = 6·19. Luster vitreous to submetallic, dull. Color dark reddish brown, becoming black on the surface.

**Comp.**—Perhaps $2PbO.Mn_2O_3.2SiO_2$ = Silica 16·6, manganese sesquioxide 21·8, lead protoxide 61·6 = 100.

**Anal.**—Damour, l. c.

$SiO_2$ 15·95 $MnO_2$ 24·50 (or $Mn_2O_3$ 22·26) PbO 59·79 = 100·24

The state of oxidation of the manganese, and hence the true composition of the mineral, is not definitely settled; if $MnO_2$ is present, the formula becomes $Pb\overset{IV}{Mn}SiO_5$, which requires: $SiO_2$ 16·3, $MnO_2$ 23·5, PbO 60·2 = 100. The formula given above corresponds to that of melanotekite.

**Pyr., etc.**—B.B. on charcoal gives a lead coating and with soda a globule of lead. In a salt of phosphorus bead dissolves and gives in R.F. a slight yellowish color, after the addition of saltpeter becomes bright violet. Dissolves in part in dilute sulphuric acid with the separation of manganese oxide mixed with silica. With hydrochloric acid chlorine is disengaged.

**Obs.**—From southern Chili, exact locality unknown. Occurs with quartz, barite, apatite. Named from *κέντρον*, *spike.* See also p. 1039.

**421. MELANOTEKITE.** *G. Lindström*, Öfv. Ak. Stockh., 35, No. 6, 53, 1880. Melanotecite.

Massive.

Cleavage in two directions, in one of these most distinct. H.$=6{\cdot}5$. G.$=5{\cdot}73$. Luster metallic to greasy. Color black to blackish gray. ~~Streak~~ greenish gray. Nearly opaque but translucent in thin sections. Pleochroic, bottle-green and red brown.

**Comp.**—$Pb_2Fe_2Si_2O_9$ or $2PbO.Fe_2O_3.2SiO_2$ = Silica 16·6, iron sesquioxide 22·0, lead protoxide 61·4 = 100.

**Anal.**—1, 2, Lindström; 1, after deducting 2·36 p. c. impurities; 2, after deducting 3·30 p. c.:

| | $SiO_2$ | $Fe_2O_3$ | PbO | MnO | CaO | MgO | $K_2O$ | $Na_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 17·32 | 23·18 | 55·26 | 0·69 | 0·02 | 0·59 | 0·24 | 0·54 | ign. 0·93, X 1·27 = 100·04 |
| 2. | 17·22 | 22·81 | 58·42 | 0·57 | — | 0·33 | 0·18 | 0·33 | |

X = CuO 0·20, FeO 0·75, BaO 0·11 (?), Cl 0·14, $P_2O_5$ 0·07.

**Pyr., etc.**—B.B. fuses with intumescence to a black bead; with soda on charcoal gives a globule of lead and a lead coating. With borax reacts for iron, but on strong heating in R.F. becomes on cooling black and opaque (reduced lead), with salt of phosphorus gives a skeleton of silica Decomposed by nitric acid.

**Obs.**—Occurs with native lead, intimately mixed with magnetite and yellow garnet at Långban in Wermland, Sweden. This locality has also furnished the lead silicates, hyalotekite and ganomalite (p. 422). Named, in allusion to the related hyalotekite, from μέλας, *black*, and τήκειν, *to melt*. Lindström calls attention to the fact that of the two possible formulas for kentrolite proposed by Damour and Rath, the second corresponds exactly to the above composition of melanotekite.

---

**422. BERTRANDITE.** Nouveau mineral des environs de Nantes *E. Bertrand*, Bull. Soc. Min., 3, 96, 1880, 6, 248, 1883. Dx., ib., 5, 176, 1882. Bertrandite *Damour*, ib., 6, 252, 1883.

Orthorhombic; hemimorphic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}56885 : 1 : 0{\cdot}5973$ Penfield[1].

$100 \wedge 110 = 29° \ 38'$, $001 \wedge 101 = 46° \ 23\frac{5}{6}'$, $001 \wedge 011 = 30° \ 51'$ Pfd.

**Forms**[2]:

| | | | | |
|---|---|---|---|---|
| | *c* (001, *O*) | *f* $(130, i\text{-}\breve{3})$ | ϵ $(011, 1\text{-}\breve{i})$ | *e* $(031, 3\text{-}\breve{i})$ |
| *a* $(100, i\text{-}\bar{i})$ | *h* $(310, i\text{-}\bar{3})$ | *d* $(102, \frac{1}{2}\text{-}\bar{i})$[4] | η $(021, 2\text{-}\breve{i})$[3] | *x* $(162, 3\text{-}\breve{6})$[4] |
| *b* $(010, i\text{-}\breve{i})$ | *m* (110, *I*) | *i* $(049, \frac{4}{9}\text{-}\breve{i})$[5] | | |

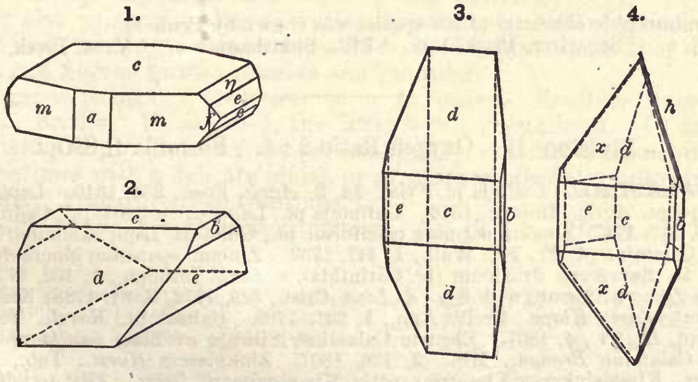


Fig. 1, Pisek, Vrba 2–4, Stoneham, Me., Pfd.

| | | | |
|---|---|---|---|
| $hh''' = 21° \ 28\frac{1}{2}'$ | $cd = {}^*27° \ 42'$ | $\eta\eta' = 100° \ 8'$ | $xx' = 28° \ 42'$ |

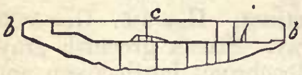
| $ff' = 60° \ 44'$ | $\epsilon\epsilon' = 61° \ 42'$ | $de = 64° \ 26'$ | |

Twins heart-shaped, with axes crossing at angles of about 60° and 120°, tw. pl. $\epsilon$ (011), perhaps also $f$ (130) and $e$ (031), but the last two not quite certain (cf. Vrba). Also tw. pl. $c$ Pfd. Crystals often tabular ‖ $c$; also ‖ $b$; often hemimorphic in the direction of the vertical axis.

5.



Mt. Antero, Pfd.

Cleavage: $m$ perfect; also $b$ and $c$, the last perhaps due to lamellar structure. H. = 6–7. G. = 2·59–2·60. Luster vitreous; pearly on $c$. Colorless to slightly yellow. Transparent. Pyroelectric, the flat plane (f. 5) $c$ + on cooling, the rounded face −.

Optically −. Ax. pl. ‖ $b$. $Bx_a \perp a$. Dispersion $\rho < v$. Axial angles:

Nantes $2H_{a.y} = 82°$ $2H_{o.y} = 118°$ $\therefore$ $2V_y = 74° 51\frac{1}{2}'$ $\beta' = 1·569$ Btd.
Mt. Antero $2K_{o.y} = 101° 10'$ $\therefore$ $(\beta = 1·569)$ $2V_{o.y} = 108° 42'$ $2V_{a.y} = 71° 18'$ Pfd.

**Comp.**—$H_2Be_4Si_2O_9$ or $H_2O.4BeO.2SiO_2$ = Silica 50·3, glucina 42·1, water 7·6 = 100.

The water goes off only at a red heat. Groth writes the formula as a basic orthosilicate.

**Anal.**—1, Damour, l. c. 2, Pfd., on 0·13 gr., l. c. 3, Preis, Zs. Kr., **15**, 200, 1889.

| | | $SiO_2$ | BeO | $H_2O$ | |
|---|---|---|---|---|---|
| 1. Barbin | G. = 2·586 | 49 26 | 42 00 | 6·90 | $Fe_2O_3$ 1·40 = 99·56 |
| 2. Mt. Antero | G. = 2·598 | 51·8 | 39·6 | 8·4 | CaO 1·0 = 100·8 |
| 3. Pisek | G. = 2·599 Vrba | 49·90 | 42·62 | 7·94 | $Al_2O_3, Fe_2O_3$ *tr.* = 100·46 |

**Pyr.**—B.B. infusible but becomes opaque. Insoluble in acid.

**Obs.**—Occurs implanted upon quartz or feldspar in cavities of a pegmatyte forming veins in gneiss at Petit-Port and at the quarries of Barbin near Nantes, France; also from la Villeder, Morbihan (Bull. Soc. Min., **12**, 514, 1889). In a feldspar quarry at Pisek, Bohemia, with corroded beryl, in part aquamarine, also apatite, tourmaline, etc. On Mt. Antero, Chaffee Co., Colorado, with phenacite and sometimes inclosing it as of earlier formation; both are implanted upon corroded aquamarine crystals. Also at Stoneham, Me., in cavities with herderite. At Amelia Court House, Va., with etched beryl.

Named for E. Bertrand, the French Mineralogist.

**Ref.**—[1] Stoneham, Am. J. Sc., **37**, 213, 1889. For Mt. Antero he obtained $\breve{a} : \bar{b} : \dot{c}$ = 0·5723 : 1 : 0 5993, ib., **36**, 52, 1888, **40**, 490, 1890. Scharizer suggested a monoclinic form for the Pisek mineral, Zs. Kr., **14**, 33, 1888, which is not confirmed by optical characters nor by Vrba's measurements, Zs. Kr., **15**, 194, 1889; the latter shows that there is an apparent relation in form to calamine, although the formulas differ by one molecule of water, thus:

*Bertrandite* $\frac{3}{4}\breve{a} : \dot{c} : \frac{1}{4}\bar{b}$ = 0·7243 : 1 : 0·4186 Stoncham, Pfd.
" 0·7191 : 1 : 0·4206 Pisek, Vrba.
*Calamine* $\breve{a} : \bar{b} : \dot{c}$ = 0·7834 : 1 : 0·4778 Schrauf.

The hemimorphic character of the species was shown by Penfield.

$bu = 73° 8'$
$it = 74° 4'$

Twins: tw. pl. *c*, axes parallel and antilogous poles of crystals together. Crystals hemimorphic with the upper extremity, the analogous pole, often highly modified with macrodomes and brachydomes prominent, and the lower, the antilogous pole, terminated by the pyramids *u*, *v*, also *e*, or with *e* rounded and rarely *π* and *c*[8]. Usually implanted and showing one extremity only. Crystals often tabular ∥ *b*; also prismatic; faces *b* vertically striated. Often grouped in sheaf-like forms and forming drusy surfaces in cavities. Also stalactitic, mammillary, botryoidal, and fibrous forms; massive and granular.

Cleavage: *m* perfect; *s* (101) less so; *c* in traces. Fracture uneven to subconchoidal. Brittle. H. = 4·5–5, the latter when crystallized. G. = 3·40–3·50, 3·43–3·49, Altenberg. Luster vitreous; *c* subpearly, sometimes adamantine. Color white; sometimes with a delicate bluish or greenish shade; also yellowish to brown. Streak white. Transparent to translucent.

Optically +; double refraction strong. Ax. pl. ∥ *a*. $Bx_a \perp c$. Indices and axial angles:

$\alpha_r = 1·61069$ $\beta_r = 1·61416$ $\gamma_r = 1·63244$ $\therefore$ $2V_r = 47° 30'$ $2E_r = 81° 7'$ Lang
$\alpha_y = 1·61358$ $\beta_y = 1·61696$ $\gamma_y = 1·63597$ $\therefore$ $2V_y = 46° 9'$ $2E_y = 78° 39'$ "
$\alpha_{gr} = 1·61706$ $\beta_{gr} = 1·62020$ $\gamma_{gr} = 1·63916$ $\therefore$ $2V_{gr} = 44° 42'$ $2E_{gr} = 76° 31'$ "

Also, measured $2E_r = 81° 3'$ $2E_y = 78° 7'$ $2E_{gr} = 76°$ Lang[12]
$2E_r = 82° 30'$ $2E_y = 80°$ $2E_{gr} = 75°$ Dx.
$2E_r = 85° 21'$ at 8°·8, 82° 50′ at 17°, 77° 50′ at 95°·5, 76° 32′ at 121° Dx.

Strongly pyroelectric, the more highly modified extremity of the crystals (as ordinary developed, cf. f. 4) the analogous pole, the lower the antilogous;

in twins the latter poles in contact. See Riess and Rose[13]; also later Bauer and Brauns[13], who used the Kundt method of investigation and describe the results with great fullness.

**Var.**—1. *Ordinary.* (*a*) In crystals as described above. (*b*) Mammillary or stalactitic. (*c*) Massive; often cellular. *Wagite* is a concretionary light blue to green calamine from Nizhni Yagurt in the Ural; G. = 2·707.

2. *Carbonated.* Sullivan has described (Dublin Q. J. Sc., **2**, 150, 1862) a variety of calamine from the Dolores mine in the province of Santander, Spain, occurring in concentric pisolitic masses, frequently containing a semitranslucent, opal-like nucleus. This mineral, produced from the hydrous carbonate by the action of silicated waters, contains from 12 to 20 per cent. of zinc carbonate; G. = 2·88–3·69.

3. *Argillaceous.* Another calamine from Spain, analyzed by Schönichen (B. H. Ztg., **22**, 163), contains 20 to 26 p. c. of alumina, with 31·5 p. c. of silica, 21 to 28·5 p. c. of zinc oxide, and 18 to 20 of water; and is apparently calamine mixed with clay. It occurs massive; color at first white, changing in the air to violet, brown, and finally black; feel soapy.

Clays carrying varying amounts of zinc silicate are common in the zinc regions of southwestern Missouri, and occur also in Virginia. Those of Missouri include: (1) the red, rather tough and harsh "joint clays" and (2) the "tallow clays" with greasy feel, yellowish, ash-gray, or brown colors after drying. The latter occur in layers of several inches in thickness up to two or three feet and in lumps from 50 to 500 lbs. or more. The "tallow clays" are very fine grained, plastic, and on drying shrink and crumble into small fragments. The amount of zinc oxide present varies chiefly between 30 and 40 p. c. See further W. H. Seamon, Am. J. Sc., **39**, 38, 1890. A lithomarge-like clay from the Bertha zinc mine, Pulaski Co., Virginia, contained 12 p. c. ZnO, B. H. Heyward, Ch. News, **44**, 207, 1881.

**Comp.**—$H_2Zn_2SiO_5$ or $H_2O.2ZnO.SiO_2$ = Silica 25·0, zinc oxide 67·5, water 7·5 = 100. The water is basic since (Fock) it goes off only at a red heat, the mineral being unchanged at 340° C. The formula is probably $(ZnOH)_2SiO_3$ or a basic metasilicate.

For analyses see 5th Ed., p. 408. Also 1, Genth., Am. Phil. Soc., **23**, 46, 1886. 2, Eyerman, Am. J. Sc., **37**, 501, 1889.

| | $SiO_2$ | ZnO | $H_2O$ | |
|---|---|---|---|---|
| 1. Pulaski Co., Va. | 25·01 | 67·42 | 8·32 | = 100·75 |
| 2. Friedensville | 24·32 | 65·05 | 7·86 | $Fe_2O_3$ 2·12 = 99·15 |

**Pyr., etc.**—In the closed tube decrepitates, whitens, and gives off water. B.B. almost infusible (F. = 6); moistened with cobalt solution gives a blue color when heated. On charcoal with soda gives a coating which is yellow while hot, and white on cooling. Moistened with cobalt solution, and heated in O.F., this coating assumes a bright green color. Gelatinizes with acids even when previously ignited. Decomposed by acetic acid with gelatinization. Soluble in a strong solution of caustic potash.

**Obs.**—Calamine and smithsonite are usually found associated in veins or beds in stratified calcareous rocks accompanying sulphides of zinc, iron, and lead. Thus at Aix-la-Chapelle; Raibel and Bleiberg, in Carinthia, in the upper Triassic; Moresnet in Belgium, Freiburg in Baden, Iserlohn, Tarnowitz, Olkucz, Miedzanagora, Rezbánya, Schemnitz. At Roughten Gill, in Cumberland, in acicular crystals and mammillary crusts, sky-blue and fine green; at Alston Moor, white; at the Rutland mine, near Matlock, in Derbyshire, in brilliant crystals, and grayish white and yellow, and mammillary; at Castleton, in crystals; on the Mendip Hills, mostly brownish yellow, and in part stalactitic; in Flintshire, etc., Wales; Leadhills, Scotland. Large crystals have been found at Nerchinsk, in Eastern Siberia.

In the United States occurs at Sterling Hill, near Ogdensburg, N. J., in fine clear crystalline masses In Pennsylvania, at the Perkiomen and Phenixville lead mines; in a lower Silurian rock two miles from Bethlehem, at Friedensville, in Saucon valley, abundant and extensively worked: on the Susquehanna, opposite Selinsgrove. Abundant in Virginia, at Austin's mines in Wythe Co. A pale yellow, fusible zinciferous clay occurs in considerable abundance with calamine at the Ueberroth mine, Friedensville. With the zinc deposits of southwestern Missouri, especially about Granby, both as crystallized and massive calamine, and mixed with an aluminous silicate forming the "tallow clays" above described. According to Seamon (l. c.) the calamine has been gradually crystallized out of the zinciferous clays, these having been first formed. At the Emma mine, Cottonwood Cañon, Utah, in greenish blue mammillary forms with wulfenite and cerussite.

The name *Calamine* (with *Galmei* of the Germans) is commonly supposed to be a corruption of *Cadmia.* Agricola says it is from *calamus*, a *reed*, in allusion to the slender forms (stalactitic) common in the *cadmia fornacum.*

The *cadmia* of Pliny and of other ancient authors included both the native silicate and carbonate, and the oxide from the chimneys of furnaces (cadmia fornacum). The two native ores continued to be confounded under the name *lapis calaminaris*, *calamine* or *galmei*, until investigated chemically by Smithson in 1803. Earlier analyses had made out chemical differences, and some authors, before 1790, had rightly suggested a division of the species: Bergmann having found 28 p. c. carbon dioxide in a Holywell specimen (J. Phys., **16**, 17, 1780); and Pelletier, in a kind from Freiburg in Breisgau, which had been called *Zeolite of Breisgau* because it gelatinized with acids, 52 p. c. silica, with 36 zinc oxide, and 12 water (J Phys., **20**, 420, 1782); and Klaproth, in another, similarly gelatinizing, 66 zinc oxide and 33 silica. But Smithson was the first to make known the true composition, and clear away all doubts.

De Lisle noticed the crystalline forms of the two species, describing one kind as prismatic with dihedral summits, and the other as scalenohedral like dogtooth spar, yet did not fully appreciate the importance of the observation; while Haüy, 14 years later, in his *Traité*, describes only the crystals of the *silicate*, and takes the ground that the *zinc carbonatée* was only an impure calcareous "zinc oxydé."

In 1807 Brongniart called the silicate *calamine*, leaving for the other ore the chemical name *zinc carbonatée*. In 1832, Beudant followed Brongniart in the former name, and designated the latter *Smithsonite* after SMITHSON, who had analyzed in 1803 the carbonate as well as silicate. Thus the two species were, at last, not only distinguished, but mineralogically named.

Unfortunately, Brooke & Miller, in 1852, reversed Beudant's use of these names, with no good reason; and in 1853, Kenngott, on account of the confusion of names, as he says, introduced for the silicate the new name *Hemimorphite*, and so added to the confusion. These innovations should have no favor.

MORESNETITE *Risse*, Vh. Ver. Rheinl., C.-Bl., 98, 1865. A mineral from Altenberg, near Aachen, occurring with calamine. Two varieties are found, one dark to leek-green and opaque; the other light emerald-green, transparent. The latter is the purest; it has H. = 2·5, conchoidal fracture, streak white. It afforded on analysis: $SiO_2$ 30·31, $Al_2O_3$ 13·68, FeO 0·27, NiO 1·14, ZnO 43·41, MgO *tr.*, CaO *tr.*, $H_2O$ 11·37 = 100·18. Difficultly soluble in acids.

VANUXEMITE *C. U. Shepard*, Contrib. Min., 1876. A product of the decomposition of zinc ores at Sterling Hill, N. J. Occurs in irregular white patches in a firm ochery aggregate. G. = 2·5. Does not adhere to the tongue, but emits a slight clayey odor on being breathed upon. An analysis gave: $SiO_2$ 35·64, $Al_2O_3$ 11·70, ZnO 32·48–36·0, $H_2O$ 14·80–19·88. Obviously a mixture of white clay with zinc silicate.

## 424. CARPHOLITE. Karpholith *Wern.*, Letztes Min. Syst., **10**, 43, 1817. Strohstein *Germ.* Strawstone.

Monoclinic. Prismatic angle 68° 33′. In radiated and stellated tufts, and groups of acicular crystals. Twins: tw. pl. *a* (100).

Very brittle. H. = 5–5·5. G. = 2·935. Luster silky, glistening. Color pure straw-yellow to wax-yellow. Pleochroism distinct: $\mathfrak{c}$ colorless, $\mathfrak{b}$, $\mathfrak{a}$ pale yellow. Optically −. $Bx_a \perp b$ (010). $Bx_o \wedge \dot{c} = 3°$ to 5° Lévy-Lcx.[1] 2V = 60° approx.

**Comp.**—$H_4MnAl_2Si_2O_{10}$ or $2H_2O.MnO.Al_2O_3.2SiO_2$ = Silica 36·5, alumina 31·0, manganese protoxide 21·5, water 11·0 = 100.

The water goes off at a red heat; hence probably (Groth) as a basic metasilicate.

**Anal.**—1, Hauer, Ber. Ak. Wien, **12**, 505, 1854. 2, Bülowius, Zs. G. Ges., **22**, 456, 1870. 3, Koninck, Bull. Ac. Belg., **47**, 564, 1879. For earlier analyses, 5th Ed., p. 419.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Schlackenwald | 36·15 | 19·74 | 9·87 | 20·76 | — | — | — | 2·56 | 10·19 | F 1·74 = 101·01 |
| 2. Wippra, Harz | 38·02 | 29·40 | 2·89 | — | 4·07 | 11·78 | 1·80 | — | 10·17 | Alk. 0·46, quartz 1·17 = 99·76 |
| 3. Meuville | 37·15 | 30·11 | 2·27 | — | — | 17·97 | 0·41 | — | 11·22 | Alk. 0·54, CuO 0·33 = 100 |

From 3, 34 p. c. quartz have been deducted.

**Pyr., etc.**—In the closed tube gives water, which reacts acid and attacks the glass (fluorine). B.B. swells up and fuses at 3·5 to a brown glass. With the fluxes gives reactions for manganese and iron. Not decomposed by hydrochloric acid. Decomposed on fusion with alkaline carbonates.

**Obs.**—Occurs in minute divergent tufts, disposed on granite, with fluorite and quartz, in the tin mines of Schlackenwald: also at Wippra in the Harz on quartz; near Meuville in the Ardennes in quartz pebbles; in the Beaujolais, France. It was named by Werner in allusion to its color, from κάρφος, *straw*.

**Ref.**—[1] Min. Roches, 164, 1888.

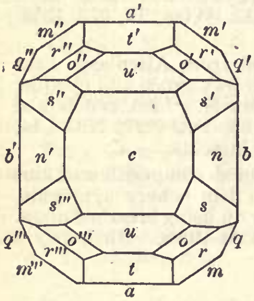
**425. CERITE.** Ferrum calciforme terra quadam incognita intime mixtum, Tungsten von Bastnäs, *Cronstedt*, Ak. H. Stockholm, 1751, Min., 183, 1758. Cerit *His. & Berz.*, Cerium en ny Metal, etc., 1804, Gehlen's J., **2**, 397, 1804, Afh., **1**, 58. 1806. Ochroit *Klapr.*, Gehlen's J., **2**, 303, 1804. Kieselcerit *Germ.* Lanthanocerit *Hermann*, J. pr. Ch, **82**, 406, 1861.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·9988 : 1 : 0·8127$ A. E. Nordenskiöld[1].
$100 \wedge 110 = 44° 58'$, $001 \wedge 101 = 39° 8'$, $001 \wedge 011 = 39° 6'$.

**Forms:** *c* (001, *O*) *u* (101, 1-$\bar{i}$) *n* (011, 1-$\breve{i}$) *r* (321, 3-$\frac{3}{2}$)
*a* (100, *i*-$\bar{i}$) *m* (110, *I*) *t* (301, 3-$\bar{i}$) *o* (523, $\frac{5}{3}$-$\frac{5}{2}$) *s* (134, $\frac{3}{4}$-$\breve{3}$)
*b* (010, *i*-$\breve{i}$) *q* (130, *i*-$\breve{3}$)

*mm'''* = *89° 56′ *tt'* = 135° 27′ *ao* = 39° 59′ *bs* = 59° 9′
*qq'* = 36° 55′ *nn* = 78° 12 *ar* = 38° 1′ *oo'''* = 35° 39′
*au* = *50° 52′ *co* = 32° 43′ *ss'* = 19° 42½′ *rr'''* = 63° 17′
*uu'* = 78° 16′

Crystals rare, highly modified; habit short prismatic. Commonly massive; granular.



Cleavage not observed. Fracture splintery. Brittle. H. = 5·5. G. = 4·86 Nd.; 4·912 Haid. Luster dull adamantine or resinous. Color between clove-brown and cherry-red, passing into gray. Streak grayish white. Slightly subtranslucent.

**Comp.**—A silicate of the metals of the cerium group with iron and calcium in small amount, also water; formula doubtful.

Rammelsberg's analysis corresponds nearly to $3H_2O.2Ce_2O_3.3SiO_2$ which requires: Silica 20·1, cerium trioxide 73·8, water 6·1 = 100. Lindström's analysis, however, gives approximately $3H_2O.2(Ca,Fe)O.3Ce_2O_3.6SiO_2$; Groth writes the formula $(Ca,Fe)(CeO)(OH)_3Ce_2(SiO_3)_3$.

On the rare earths in cerite. cf. Crookes, Ch. News, **54**, 21, 40, etc.; also Krüss and Nilson, Öfv. Ak. Stockh., **44**, 371, 1887; the latter identity didymium chiefly, also samarium.

Hermann (l. c.) gave the name *lanthanocerite* to the mineral analyzed by him, which he found to contain lanthanum and didymium chiefly, with but little cerium.

**Anal.**—1, Rg., Pogg., **107**, 631, 1859. 2, Lindström, Öfv. Ak. Stockh., **30**, 13, 1873. 3, Stolba and Kettner, Ber. Böhm. Ges., 372, 1879. Also Hisinger, Hermann, Kjerulf, see 5th Ed., p. 414.

| | $SiO_2$ | $Ce_2O_3$ | $Di_2O_3,La_2O_3$ | FeO | $Al_2O_3$ | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. | 19·18 | 64·55 | 7·28 | 1·54 | — | 1·35 | 5·71 | = 99·61 |
| 2. G. = 4·86 | 22·79 | 24·06 | 35·37 | 3·92 | 1·26 | 4·35 | 3·44 | gangue 4·33 = 99·52 |
| 3. | 18·18 | 33·25 | 34·60 | 3·18 | — | 1·69 | 5·18 | = 96·08 |

**Pyr., etc.**—In a matrass yields water. B.B. infusible alone; with borax in the outer flame forms a yellow globule, which becomes almost colorless on cooling; in the inner flame a weak iron reaction. With soda not dissolved, but fuses to a dark yellow slaggy mass. Gelatinizes with hydrochloric acid.

**Obs.**—Occurs at Bastnäs, near Riddarhyttan, in Westmanland, Sweden, forming a bed in gneiss, and associated with mica, hornblende, chalcopyrite, cerine (allanite), etc. It bears considerable resemblance to the red granular variety of corundum, but is readily distinguished by its inferior hardness.

Hisinger and Berzelius, in 1803–4, detected in this mineral a new metal which they named *cerium*, after the planet *Ceres*, then recently announced; and the mineral they called *cerite*. Klaproth made the same discovery about the same time, and gave the name *ochroite* to the mineral, and *ochroite earth* to the new earth (alluding to its color, from ὠχρός, *brownish yellow*). In his Beiträge, 1807, Klaproth accepted the names of Hisinger and Berzelius, yet added a syllable (lest they should appear to come from κηρα, *wax*), making them *cererium* and *cererite*—a change not accepted. In 1839 Mosander proved that the oxide of cerium contained the new metal *lanthanum*, and in 1842 another new metal, *didymium*.

Crystals usually prismatic in habit, often slender to acicular; rarely flattened, the prism nearly wanting. Prismatic faces strongly striated vertically, and the crystals hence often much rounded to barrel-shaped. The triangular prism *m* $(10\bar{1}0)$ frequently predominating, the complementary form *m,* $(01\bar{1}0)$ then absent or subordinate; also the hexagonal prism *a* $(11\bar{2}0)$ present alone; or, again, *m* with *a*; the cross-section of the prism then, respectively, three-sided, six-sided, or nine-sided. Crystals commonly hemimorphic (cf. figures); the rhombohedron *r* $(10\bar{1}1)$ occurring on the edges of the trigonal prism *m* $(10\bar{1}0)$ at the antilogous end (see below); also the rhombohedron *o* $(02\bar{2}1)$ and scalenohedron *u* prominent at the antilogous end (Pierrepont, Gouverneur, Pfd., cf. f. 5, 6, 9, 10). Penetration-twins with parallel axes not common; also rare, a cruciform-twin with *r* as tw. pl.[3] Crystals sometimes isolated but more commonly in parallel and radiating groups. Sometimes massive compact; also columnar, coarse or fine, parallel or divergent.

Cleavage: *a*, *r* difficult. Fracture subconchoidal to uneven. Brittle and often rather friable. H. = 7–7·5. G. = 2·98–3·20. Luster vitreous to resinous. Color black, brownish black, bluish black, most common; blue, green, red, and sometimes of rich shades; rarely white or colorless; some specimens red internally and green externally; and others red at one extremity, and green, blue, or black at the other. Streak uncolored. Transparent to opaque.

Strongly dichroic, especially in deep colored varieties; axial colors varying widely.[5] Absorption for the ordinary ray $\omega$ (vibrations $\perp \dot{c}$) much stronger than for the extraordinary ray $\epsilon$ (vibrations $\parallel \dot{c}$); thus sections $\parallel \dot{c}$ transmit sensibly the extraordinary ray only, and hence their use (*e.g.*, in the tourmaline tongs) for giving polarized light. Exhibits idiophanous figures.[6] Optically —. Double refraction strong. Sometimes abnormally biaxial.[7] Refractive indices[4]:

| | | | |
|---|---|---|---|
| *Colorless* | $\omega_y$ = 1·6366 Na | $\epsilon_y$ = 1·6193 | Dx. |
| " | $\omega_y$ = 1·6397 | $\epsilon_y$ = 1·6208 | Miklucho-Maclay |
| *Green* | $\omega_r$ = 1·6408 | $\epsilon_r$ = 1·6203 | Senarmont |
| *Bl. green* | $\omega_r$ = 1·6415 | $\epsilon_r$ = 1·6230 | " |
| *Blue* | $\omega_r$ = 1·6435 | $\epsilon_r$ = 1·6222 | " |
| " | $\omega_y$ = 1·6530 | $\epsilon_y$ = 1·6312 Na | Schwebel |
| " | $\omega_{bl}$ = 1·6564 | $\epsilon_{gr}$ = 1·6343 Tl | " |
| *Green, chrom. var.* | $\omega_r$ = 1·6579 approx. | $\epsilon_r$ = 1·62407 Li | Arzruni |
| | $\omega_{gr}$ = 1·6870 " | $\epsilon_y$ = 1·63733 Na | " |
| | | $\epsilon_{gr}$ = 1·64075 Tl | " |

Erofeyev (l. c.) shows that the refractive indices vary somewhat widely with the color and even in successive layers of the same crystal.

Becomes electric by friction; also strongly pyroelectric as early investigated by Rose, and later by others.[5] The end terminated by the rhombohedron *r* (10$\bar{1}$1) and the corresponding unit prism *m* (10$\bar{1}$0) is, as above noted, with few exceptions the antilogous pole, becoming + electrified with decrease and — electrified with increase of temperature. Cf. also figs. 11, 12 from Rose.

**Var.**—*Ordinary.* In crystals as above described; black much the most common. (*a*) *Rubellite;* the red, sometimes transparent; the Siberian is mostly violet-red (*siberite*), the Brazilian rose-red; that of Chesterfield and Goshen, Mass., pale rose-red and opaque; that of Paris, Me., fine ruby-red and transparent. (*b*) *Indicolite.* or *indigolite;* the blue, either pale or bluish black; named from the indigo-blue color. (*c*) *Brazilian Sapphire* (in jewelry); Berlin-blue and transparent; (*d*) *Brazilian Emerald, Chrysolite* (or *Peridot*) *of Brazil;* green and transparent. (*e*) *Peridot of Ceylon;* honey-yellow. (*f*) *Achroïte;* colorless tourmaline, from Elba. (*g*) *Aphrizite;* black tourmaline, from Kragerö, Norway. (*h*) *Columnar* and *black;* coarse columnar. Resembles somewhat common hornblende, but has a more resinous fracture, and is without distinct cleavage or anything like a fibrous appearance in the texture; it often has the appearance on a broken surface of some kinds of soft coal.

*Dravite* of Tschermak is the brown, greenish black or brownish black magnesium tourmaline from Unterdrauburg in the Drave district in Carinthia.

The varieties based upon composition fall into three prominent groups, between which there are many gradations:

1. ALKALI TOURMALINE. Contains sodium or lithium, or both; also potassium. G. = 3·0–3·1. Color red to green; also colorless.

2. IRON TOURMALINE. G. = 3·1–3·2. Color usually deep black.

3. MAGNESIUM TOURMALINE. G. = 3·0–3·09. Usually yellow-brown to brownish black; also colorless (anal. 54).

A *chromium tourmaline* has also been described (anal. 71, 72). G. = 3·120. Color dark green.

**Comp.**—A complex silicate of boron and aluminium, with also either magnesium, iron, or the alkali metals, prominent. Formula uncertain. According to early investigations of Rammelsberg, recently reviewed and extended, the oxygen ratio of Si : R is in general 2 : 3 and the formula may hence be written:

$$\overset{\text{I}}{\text{R}}_6\text{SiO}_5 = \overset{\text{II}}{\text{R}}_3\text{SiO}_5 = \overset{\text{III}}{\text{R}}_2\text{SiO}_5.$$

Here $\overset{\text{I}}{\text{R}}$ = Na,Li,K; $\overset{\text{II}}{\text{R}}$ = Mg,Fe,Ca; $\overset{\text{III}}{\text{R}}$ = Al,B,Cr,Fe.

[a] $Fe_2O_3$.   [b] NiO.   [c] NiO.   [d] At 105° 0·07.

Riggs, as the result of a series of new analyses (anal. 36–55), gives as the general formulas for the three types:

*Lithium T.* $4H_2O.2(Na,Li)_2O.3B_2O_3.8Al_2O_3.12SiO_2$.
*Iron T.* $4H_2O.Na_2O.4FeO.3B_2O_3.7Al_2O_3.12SiO_2$.
*Magnesium T.* $4H_2O.\frac{2}{3}Na_2O.\frac{28}{3}MgO.3B_2O_3.5Al_2O_3.12SiO_2$.

Jannasch and Calb (l. c.) have deduced the general formula $R_9(BO_2)(SiO_4)_2$, and the special formulas:

*Lithium T.* $7H_2O.4(Li,Na)_2O.4FeO.6B_2O_3.15Al_2O_3.24SiO_2$.
*Iron T.* $7H_2O.2Na_2O.9FeO.6B_2O_3.14Al_2O_3.24SiO_2$.
*Magnesium T.* $7H_2O.2Na_2O.12MgO.6B_2O_3.13Al_2O_3.24SiO_2$.

The composition of the differently colored portions of the same crystal has been specially investigated by Scharizer, cf. anals. 65–67.

**Anal.**—1–34, Rg., 1850–1870 (Pogg., **80**, 449, **81**, 1, 1850; **139**, 379, 547, 1870); the analyses are quoted in the form given in Min. Ch., p. 540 *et seq.*, 1875. 35, Id., Abh. Ak. Berl., 1889 (read Feb. 14). Cf. also Jb. Min., **2**, 149, 1890.

36–55, Riggs, Am. J. Sc., **35**, 35, 1888. 56–64, Jannasch and Calb, Ber. Ch. Ges., **22**, 216, 1889, also Calb (or Kalb), Inaug. Diss., Göttingen, 1890. 65–67, Scharizer, Zs. Kr., **15**, 337, 1889. 68, Sauer, Zs. G. Ges., 38, 704, 1886. 69, Sommerlad, Zs. G. Ges., **36**, 649, 1884. 70, Engelmann, Inaug. Diss., Bonn, p. 19, 1877. 71, Cossa and Arzruni, Zs. Kr., **7**, 1, 1882. 72, Chatard, Johns Hopkins Univ. Circular, No. 75, 1889. For analyses see pp. 554, 555.

**Pyr., etc.**—The magnesia varieties fuse rather easily to a white blebby glass or slag; the iron-magnesia var. fuse with a strong heat to a blebby slag or enamel, either white, greenish, or brownish; the iron var. fuse with difficulty, or, in some, only on the edges, to a brownish, brownish red, gray, or black slag; the iron-magnesia-lithia var. fuse on the edges, and often with great difficulty, to a yellowish, grayish, bluish, or whitish slag or enamel, and some are infusible; the lithia var. are infusible, but becoming white or paler, sometimes, as the Paris (Me.) rubellite, affording a fine enamel on the edges (R.). With the fluxes many varieties give reactions for iron and manganese. Fused with a mixture of potassium bisulphate and fluor spar gives a strong reaction for boric acid. By heat alone tourmaline loses weight from the evolution of silicon fluoride and perhaps also boron fluoride, and only after previous ignition is the mineral completely decomposed by hydrofluoric acid. Not decomposed by acids (Rg.). After fusion perfectly decomposed by sulphuric acid (Kbl.), and gelatinizes with hydrochloric acid.

**Obs.**—Tourmaline is usually found in granite, gneiss, syenite, mica schist, chloritic or talcose schist, dolomite, granular limestone; sometimes as a result of contact metamorphism near dikes of igneous rocks, thus adjoining a granite vein at Mt. Willard, N. H. (see Hawes, Am. J. Sc., **21**, 21, 1881). The variety in granular limestone or dolomite is commonly brown; the bluish black var. sometimes associated with tin ores; the brown with titanium.

Many foreign localities are mentioned above. Small brilliant black crystals in decomposed feldspar, at Sonnenberg near Andreasberg in the Harz, are called *aphrizite*. Rubellite and green tourmaline occur near Ekaterinburg in the Ural; beautiful pink crystals are found at Elba; green at Campolongo in Tessin, Switzerland; also from the Binnenthal, green to yellow; red to green, blue and black at Penig, Saxony; red and green varieties at Wolkenburg; also deep green and red in the province Minas Geraes, Brazil; yellow and brown from Ceylon; dark brown varieties from Eibenstock, Saxony; the Zillerthal; black from Arendal, Norway; Snarum; Kragerö. The chrome tourmaline (anal. 71) is from the chromite deposits at Nizhni Isetsk in the Sysersk district in the Ural. Indicolite is found at Utö, Sweden. Pale yellowish brown crystals in talc at Windisch Kappel in Carinthia; white specimens (*achroïte*) come from St. Gothard, Siberia, and Elba. In Great Britain, fine black crystals have been obtained near Bovey Tracey in Devon; also found in Cornwall at different localities; green near Dartmoor in Devon; black near Aberdeen in Scotland, and elsewhere; dark brown at Dalkey in Co. Dublin, Ireland; green near Dunfanaghy, Co. Donegal; green and red at Ox mountain, near Sligo.

In the U. States, in *Maine* at Paris and Hebron, magnificent red and green tourmalines with lepidolite, etc., some crystals over an inch in diameter, transparent, ruby-red within, surrounded by green, or red at one extremity and green at the other; also blue and pink varieties; and at Norway; pink at Rumford, embedded in lepidolite; at Auburn in clear crystals of a delicate pink or lilac with lepidolite, etc.; at Albany, green and black; at Streaked Mtn., black. In *Mass.*, at Chesterfield, red, green, and blue, in a granite vein with albite, uranite and microlite, the crystals small and curved, nearly opaque, and fragile, the green crystals often with distinct prisms of red color inside, especially when in smoky quartz: at Goshen, similar, blue and green, in great perfection; at Norwich, New Braintree, and Carlisle, good black crystals. In *N. Hamp.*, Alstead, Grafton, Sullivan, Acworth, and Saddleback Mt.; at Orford, large brownish black crystals abundant in steatite. In *Vermont*, at Brattleboro, black. In *Conn.*, at Monroe, perfect dark brown crystals in mica-slate near Lane's mine, sometimes two inches in length and breadth; at Haddam, fine black crystals in mica slate with anthophyllite, also in granite with iolite, and also at the gneiss quarries, on the east side of the river; at New Milford, black crystals with beryl and mica; black at Newtown, Bethel, and Waterbury; bluish black at Branchville.

In *N. York*, near Gouverneur, light and dark brown crystals, often highly modified, with tremolite, apatite, and scapolite in granular limestone, at Canton; in simple prisms in the same rock near Port Henry, Essex Co., sometimes as a shell inclosing feldspar; at Schroon, with chondrodite and scapolite; at Newcomb, Essex Co., in brown crystals; at Crown Point, fine brown crystals; at the chrysoberyl locality near Saratoga, N. Y., black; at Alexandria, Jefferson Co.; at Kingsbridge, brown, yellowish or reddish brown crystals in dolomite; near Edenville, gray or bluish gray and green in three-sided prisms occur; short black crystals in the same vicinity, and at Rocky Hill, sometimes 5 inches in diameter; a mile southwest of Amity, yellow and cinnamon-colored crystals with spinel in calcite; also near the same village a clove-brown variety with hornblende and rutile in granular limestone; in splendent black crystals at Pierrepont, St. Lawrence Co.; colorless and glassy at De Kalb; dark brown at McComb. In *N. Jersey*, at Franklin, Hamburg, and Newton, black and brown crystals in limestone, with spinel; also grass-green crystals in crystalline limestone near Franklin. In *Penn.*, at Newlin, Chester Co.; at London Grove and near Unionville, of a light yellow or brownish yellow, in limestone, and rarely *white;* at Parksburg, Chester Co.; in Delaware Co., at Aston; at Chester, fine black; Middletown, black; Marple, of a green color in talc; in New Garden township, Chester Co., in limestone, light brown to yellow and sometimes transparent; near New Hope on the Delaware, large black crystals, in which the prismatic faces are sometimes almost wanting. A chrome-var. from the chromite beds in Montgomery Co., *Maryland.* In *N. Car.*, Alexander Co., in fine black crystals with emerald and hiddenite; green at Silver Creek, Burke Co. In *S. Car.*, in Cheowee valley. In *Georgia*, Habersham Co. In *California*, black crystals, 6–8 in. in diameter, in feldspar veins, in the mountains between San Diego and the Colorado desert, bordering the elevated valley of San Felipe.

In *Canada*, in the province of Quebec, superb greenish yellow or yellowish brown crystals, 1 inch through, in limestone at Calumet Falls, Litchfield, Pontiac Co.; transparent and brown at Hunterstown, with vesuvianite and garnet; fine brown crystals at Clarendon, Pontiac Co.; black at Grenville and Argenteuil, Argenteuil Co.; St. Jérôme, Terrebonne Co. In Ontario, in fine crystals at North Elmsley, N. Burgess and Bathurst, Lanark Co.; Blythfield, Renfrew Co.; Galway and Stoney L. in Dummer, Peterborough Co.; Charleston L. in Leeds Co.

The name *turmalin* from *Turamali* in Cingalese (applied to zircon by jewelers of Ceylon) was introduced into Holland in 1703, with a lot of gems from Ceylon. The property of attracting the ashes of burnt peat, after friction, led to its being very soon named in Holland *Aschentrecker*, or *ash-drawer.* In 1717, Lemery, in his Memoir in the Hist. de l'Acad. des Sc., France, referred the attraction to magnetism; and in 1756 to 1762, appeared the several Memoirs of Æpinus (published in the Mem. Acad. Berlin, vol. **12**, and at St. Petersburg) on the *electrical* properties of tourmaline. The name *tourmaline* was slow of introduction into mineralogical treatises. The first specimens from Ceylon were cut gems, so that the common characteristics of tourmaline and schorl were not apparent. Linnæus, in his Syst. Nat., 1768, suggests the relation between them, but de Lisle was the first to describe Ceylon crystals, and bring the two minerals into one species. On the name *schorl*, see Introduction, p. xliv. Long after the union of tourmaline and schorl, the species continued to bear the latter of these names; and even in 1816, Jameson, in his System of Mineralogy, retains schorl as the name of the species, with *common schorl* and *tourmaline* or *precious schorl* as two subspecies.

**Alt.**—Tourmaline occurs altered to mica, chlorite, cookeite, steatite. The mica is lepidolite, a species which is related in composition to some tourmaline, and is a frequent associate of the red and green varieties. It appears to take place through the addition of alkalies. Some rubellites and green tourmalines at Chesterfield are hollow, evidently from decomposition and removal of the interior; and in the cavities are occasionally observed small crystals of yellow uranite (Teschemacher).

Zeuxite, of Thomson, Min., **1**, 320, 1836, was found in 1814 in acicular interwoven prismatic crystals at Huel Unity, Cornwall; color brown, slightly greenish in some lights; G. = 3·051; H. = 4·25. Greg shows that the mineral is a ferriferous tourmaline (Phil. Mag., **10**, 118, 1855); this is confirmed by Dx. (Min., **2**, xliv, 1874).

**Ref.**—[1] Preisschrift, p. 112, 1825; Kupffer deduces from his measurements $rr' = 46° 47'$ black, $= 46° 52'$ green, $= 46° 58'$ red. The angle 46° 52', which is about the mean of these, has been accepted by Miller, Dx., et al. It is, however, rather variable. Erofeyev gives 46° 54', Vh. Min. Ges., **6**, 81–108, 1871. In the 5th Ed., the rhombohedron with a terminal angle of 77° was taken as the fundamental form because it showed a certain relation to calcite (see Am. J. Sc., **17**, 216, 1854). The probable tetartohedral character was first noted, though with some question, by Erofeyev (l. c.) and confirmed by Ramsay, Vet. Ak. Handl. Bih., **12** (2), No. 1, 1886; cf. also Solly, Min. Mag., **6**, 80, 1884.

[2] For lists of forms, with authorities, critical remarks as to doubtful forms, original observations, etc., see Erofeyev, l. c.; Slg., Zs. Kr., **6**, 217, 1881; Gdt., Index, **3**, 243, 1891. Min., **2**, 67, 1879. *Conductivity*, heat and electricity, S. P. Thompson and Lodge, Phil. Mag., **8**, 18, 1879, **12**, 112, 1881; Fitzgerald, Sc. Proc. Dubl. Soc., **1**, 370, 1880; Stenger, Wied., **22**, 522, 1884. *Specific heat*, Joly, Proc. R. Soc., **41**, 268, 1887.

A *boro-silicate of uranium* described by W. G. Waring (Eng. Mng. J., **49**, 356, 1890) from Pima Co., Arizona, has been shown by Kunz to be only black tourmaline.

**427. DUMORTIERITE.** *Gonnard*, Bull. Soc. Min., **4**, 2, 1881; *Bertrand*, ib., **3**, 171, 1882; and **4**, 9, 1881.

Orthorhombic. Prismatic angle approximately 60°; 56° Diller[1]. Rarely in distinct crystals with *a* (100) and *m* (110). Usually in fibrous to columnar aggregates. Twins: tw. pl. *m* (110), repeated, forming trillings Lcx.

Cleavage: *a* distinct; also prismatic, imperfect. H. = 7. G. = 3·265 Diller; 3·36 Dmr. Luster vitreous. Color bright smalt-blue to greenish blue. Transparent to translucent.

Pleochroism very strong: 𝔠 colorless, 𝔟 reddish violet, 𝔞 deep ultramarine-blue. Exhibits idiophanous figures, analogous to andalusite. Optically −. Ax. pl. ∥ *b*. Bx ⊥ *c*. Dispersion $\rho < v$ Btd.; $\rho > v$ Lévy-Lcx.

**Comp.**—Essentially a basic aluminium silicate. Perhaps $Al_8Si_3O_{18}$ or $4Al_2O_3.3SiO_2$ = Silica 30·6, alumina 69·4 = 100. Part of the aluminium seems to be replaced by boron.

**Anal.**—1, Damour, Bull. Soc. Min., **4**, 6, 1881. 2–4, J. E. Whitfield, Am. J. Sc., **37**, 216, 1889.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $B_2O_3$ | MgO | ign. | | |
|---|---|---|---|---|---|---|---|---|
| 1. Beaunan | 29·85 | 66·02 | 1·01 | — | 0·45 | 2·25 | | = 99·58 |
| 2. Harlem, N. Y. | 31·44 | 68·91 | — | *tr.* | — | — | | = 100·35 |
| 3. Clip, Arizona | 27·99 | 64·49 | — | 4·94 | *tr.* | 1·72 | $P_2O_5$ 0·20 | = 99·34 |
| 4. " " | 31·52 | 63·66 | — | 2·62 | 0·52 | 1·34 | Alk. 0·48 | = 100·14 |

An earlier analysis by Riggs of the Harlem mineral (Am. J. Sc., **34**, 406, 1887) showed 4·07 $B_2O_3$, but probably from tourmaline which is intimately associated with it.

**Pyr., etc.**—B.B. infusible, loses color on strong ignition; with cobalt solution a beautiful blue, characteristic of aluminium. With salt of phosphorus gives a slightly bluish opaline bead.

**Obs.**—Found in fibrous forms embedded in feldspar in blocks of gneiss at Chaponost, near Lyons, France, the original locality being near Beaunan; also at Brignais.

Also reported from Wolfshau, near Schmiedeberg, Silesia; in the iolite of the gneiss of Tvedestrand, Norway.

In the U. S., it occurs near Harlem, New York Island, in the pegmatoid portion of a biotite-gneiss; in a quartzose rock at Clip, Yuma Co., Arizona.

Named for the palæontologist, M. Eugène Dumortier.

**Ref.**—[1] Cf. Btd., l. c.; Diller, Am. J. Sc., **37**, 216, 1889.

**428. STAUROLITE.** Pierres de croix *de Robien*, N. idées sur la format. d. Foss., 109, 1751 (with figs.). Basaltes crystallisatus pt. *Cronst.* (the specimen a cross of two brown 6-sided crystals, worn as an amulet at baptisms in Basel, and called *Lapis crucifer*, and *Basler Taufstein*), Min., 70, 1758. Schorl cruciforme pt., Pierres de croix, *de Lisle*. Crist., 1772, 1783 (with figs.). Staurolite *Delameth.*, Sciagr., **1**, 298, 1792. Grenatite (fr. St. Gothard), *Saussure*, Voy. Alpes, § 1900, 1796. Granatite. Staurolith *Karst.*, Tab., 22, 1800. Staurotide *H.*, Tr., **3**, 1801. Nordmarkite *Dana*, Min., 389, 1868. Xantholite *Heddle*, Min. Mag., **3**, 59, 1879.

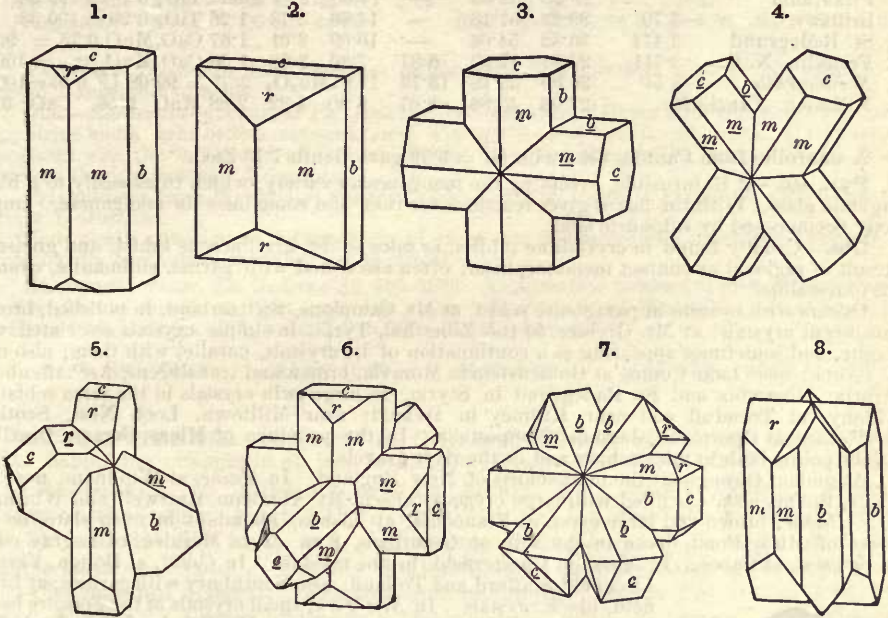
Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·4734 : 1 : 0·6828 Phillips[1].

100 ∧ 110 = 25° 20′, 001 ∧ 101 = 55° 16′, 001 ∧ 011 = 34° 19½′.

**Forms:** *b* (010, *i*-ĭ), *c* (001, *O*); *m* (110, *I*); *r* (101, 1-ī); also only as tw. planes, *y* (230, *i*-$\frac{3}{2}$), *x* (032, $\frac{3}{2}$-ĭ), *z* (232, $\frac{3}{2}$-$\frac{3}{2}$).

Angles: *mm‴* = *50° 40′, *yy‴* = 70° 45½′, *rr′* = 110° 32′, *mr* = *42° 2′, *cx* = 45° 41′, *cz* = 60° 31′.

Twins cruciform: (1) tw. pl. $x$ (032), the two crystals crossing nearly at right angles, since $cx = 45° 41'$. (2) tw. pl. $z$ (232), crossing at an angle of 60° approximately, since $cz = 60° 31'$. (3) tw. pl.[2] $y$ (rare), here $b\underline{b} = 70° 45\frac{1}{2}'$. Crystals commonly prismatic and often flattened ∥ $\bar{b}$; often with rough surfaces.



Figs. 1, 2, Simple forms. 3–5, Common twins. 6–8, Fannin Co., Ga.

Cleavage: $b$ distinct, but interrupted; $m$ in traces. Fracture subconchoidal. Brittle. H. = 7–7·5. G. = 3·65–3·75. Subvitreous, inclining to resinous. Color dark reddish brown to brownish black, and yellowish brown. Streak uncolored to grayish. Translucent to nearly or quite opaque.

Pleochroism distinct: $\mathfrak{c}$ (= $\dot{c}$) hyacinth-red to blood-red, $\mathfrak{a}$, $\mathfrak{b}$ yellowish red, Rosenbusch; or $\mathfrak{c}$ gold-yellow, $\mathfrak{a}$, $\mathfrak{b}$ light yellow to colorless. Optically +. Ax. pl. ∥ $a$. Bx ⊥ $c$. Axial angles:

$2H_{a.r} = 113° 10'$ $\beta_r = 1{\cdot}749$ $\therefore$ $2V_{a.r} = 88° 46'$ Lévy-Lcx.

$2H_{o.r} = 117° 52'$ $2V_{o.r} = 91° 39'$ Dx. $\beta_r = 1{\cdot}7526$, Mlr.

$\alpha = 1{\cdot}736$ $\beta = 1{\cdot}741$ $\gamma = 1{\cdot}746$ Lévy-Lcx.

**Comp., Var.**—Formula doubtful, perhaps $H_4(Fe,Mg)_6(Al,Fe)_{24}Si_{11}O_{66}$ or $2H_2O.6(Fe,Mg)O.12Al_2O_3.11SiO_2$ Friedl.

Coloriano gives $H_2Fe_2Al_{12}Si_5O_{31}$; Groth suggests the simpler form $HFeAl_5Si_2O_{13}$.

Impurities are usually present, especially in the form of inclosed silica, sometimes up to 30 to 40 p. c.; also garnet, mica, and perhaps magneite, brookite, cf. Rg., Lsx., Friedl, l. c. See also analyses, 5th Ed., p. 389, which give $SiO_2$ varying from 27·0 to 51·3.

*Nordmarkite* is a manganesian variety from Nordmark, Sweden, anal. 10.

*Xantholite* is a variety of somewhat anomalous composition, according to the analysis, which is probably to be explained by the presence of impurities (cf. Lcx., Bull. Soc. Min., **9**, 78, 1886).

Anal.—1, Rg., Zs. G. Ges., **25**, 53, 1873. 2, Friedl, Zs. Kr., **10**, 366, 1885. 3, Lsx., Min. Mitth., 173, 1872. 4, Coloriano, Bull. Soc. A staurolite from Canton, Ga., with G. = 3·79 gave Genth 7·13 ZnO.

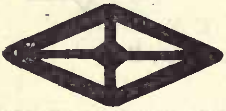
**Pyr., etc.**—B.B. infusible, excepting the manganesian variety, which fuses easily to a black magnetic glass. With the fluxes gives reactions for iron, and sometimes for manganese. Imperfectly decomposed by sulphuric acid.

**Obs.**—Usually found in crystalline schists, as mica schist, argillaceous schist, and gneiss, as a result of regional or contact metamorphism; often associated with garnet, sillimanite, cyanite, and tourmaline.

Occurs with cyanite in paragonite schist, at Mt. Campione, Switzerland, in polished, brown, translucent crystals; at Mt. Greiner, in the Zillerthal, Tyrol, in simple crystals associated with cyanite, and sometimes appearing as a continuation of its crystals, parallel with them; also near Innsbruck; near Lake Como; at Goldenstein in Moravia, brown and translucent; Aschaffenburg, Bavaria; Oberwölz and St. Radegrund in Styria; in large twin crystals in the mica schists of Brittany; at Tornduff and near Killiney in Ireland; near Milltown, Loch Ness, Scotland (*xantholite*); at Oporto, St. Jago de Compostella. In the province of Minas Geraes, Brazil, at various points both in mica schists and in the river gravels.

Abundant throughout the mica schists of New England. In *Maine*, at Windham, near the bridge, the mica slate is filled with large crystals; also at Mt. Abraham, Hartwell, and Winthrop. In *N. Hamp.*, brown and large cryst. at Franconia; at Lisbon, abundant in mica slate; on the shores of Mink Pond, loose in the soil; at Grantham, 2 m. from Meriden, of a gray color. In *Vermont*, at Cabot. In *Mass.*, at Chesterfield, in fine crystals. In *Conn.*, at Bolton, Vernon, Litchfield, Stafford, and Tolland; also Southbury with garnets; at Litchfield, black crystals. In *New York*, small crystals at the Foss ore bed in Dover, Dutchess Co.; also three and a half miles from New York City, on the Hudson; as a result of contact metamorphism in the mica schist near Peekskill, N. Y. (cf. Williams, Am. J. Sc., **36**, 254, 1888). In *Penn.*, reddish brown cryst. abundant on the Wissahickon, 8 m. from Philadelphia. In *N. Carolina*, at the Culsagee corundum mine near Franklin, Macon Co.; large coarse crystals at the Parker mine, Cherokee Co.; also in Madison and Clay counties. In *Georgia*, at the lead mine, Canton, in quartzose mica schist, the gangue of the lead ore; also in Fannin Co., loose in the soil in fine crystals.



Dr. C. T. Jackson has described a variety of staurolite in tessellated crystals like chiastolite, from Charlestown, N. H., as represented in the accompanying figure.

Named from σταυρός, *a cross*. Haüy's change of *staurolite* to *staurotide* was neither necessary nor reasonable.

**Alt.**—Occurs altered to steatite.

**Ref.**—[1] Min., 75. 1837. In some respects it would be more natural to take the twinning planes (see below) as fundamental, 011, 111, 110, when the symbols of the prism would become 320, and the axes 0·7101 : 1 : 1·0242. [2] E. S. D., Am. J. Sc., **11**, 384, 1876; this twinning can be explained as having either 230 or 130 as tw. pl.; the first gives $b\underline{b}$ = 70° 45½′ and 109′ 14½′, the second 109° 42′ and 70° 18′; the measured angle 70° 30′ hardly decides between these, but the former is the more probable as it corresponds to the two other more common laws.

**429. KORNERUPINE.** Kornerupin *J. Lorenzen*, Medd. Grönl., **7**, 19, 1884. Prismatin *A. Sauer*, Zs. G. Ges., **38**, 704, 1886.

Orthorhombic. Axes $\breve{a} : \bar{b}$ = 0·854 : 1. In fibrous to columnar aggregates, resembling sillimanite, showing in the prismatic zones the forms *m* (110), *a* (100), and *b* (010) with $mm'''$ = *81° kornerupine, = 81° 31′ prismatine.

Cleavage: prismatic, rather perfect. H. = 6·5. G. = 3·273 kornerupine; 3·341 prismatine, Ussing. Luster vitreous. White to colorless (K.), yellow-brown (Pr). Optically −. Ax. pl. ∥ 100, $Bx_a \perp$ 001. Axial angle 2E = 32½° K.

*Prismatine* $\alpha_y = 1·6691$ $\beta_y = 1·6805$ $\gamma_y = 1·6818$ ∴ $2V_y = 37° 7$ for Na
$2E_y = 65° 30'$ and from $\beta = 1·6805$ ∴ $2V_y = 37° 34'$.

**Comp.**—$MgAl_2SiO_6$ or $MgO.Al_2O_3.SiO_2$ = Silica 29·7, alumina 50·5, magnesia 19·8 = 100.

**Anal.**—1, Lorenzen, l. c. 2, Sauer, l. c.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | ign. |
|---|---|---|---|---|---|---|---|
| 1. *Kornerupine* | 3·23 | 30·90 | 46·79 | 2·02 | — | 19·46 | 1·30 = 100·47 |
| 2. *Prismatine* | 3·341 | 30·89 | 43·06 | — | 6·28 | 15·08 | 1·36 $Na_2O$ 2·04, $K_2O$ 0·79 = 99·50 |

**Pyr.**—B.B. does not fuse; becomes bright blue if moistened with cobalt solution and ignited. Insoluble in acids.

**Obs.**—*Kornerupine* occurs at Fiskernäs on the west coast of Greenland with green amphibole, sapphirine and a light brown magnesia mica; also gedrite and occasionally iolite. It is intimately associated with the iolite, and sometimes appears in a micropegmatitic form with it. Named after the Danish geologist, Kornerup.

*Prismatine* is from Waldheim, Saxony, where it forms layers in granulyte with albite, also garnet, tourmaline.

Ussing calls attention to the similarity of these two independently described minerals, and it can hardly be doubted that they are identical.

KRYPTOTIL *Sauer*, Zs. G. Ges., **38**, 705, 1886. An alteration product of prismatine, occurring in fine fibrous forms of light greenish color. Composition: $HAlSiO_4 = H_2O.Al_2O_3.SiO_2$ = Silica 50·0, alumina 42·5, water 7·5 = 100. Anal.—Sauer:

$SiO_2$ 48·43 $Al_2O_3$ 41·63 MgO 2·13 $H_2O$ 7·70 = 99·89.

**430. SAPPHIRINE.** Sapphirin (fr. Greenland) *Giesecke*, Stromeyer's Unters., **1**, 391, 1821. Sapphirine. Sapphirin pt. [rest blue Spinel] *Hausm.*, Handb., 427, 1847. Saphirine.

Monoclinic. In indistinct crystals, tabular ∥ *b*; rarely showing prismatic planes on the edges, *bm* = 57° 27′, *mm‴* = 65° 6′; also other prisms inclined 23° 34′ and 31° 36′ to *b*, and a clinodome giving $b \wedge 011 \doteq 47\frac{1}{2}°$; $\beta = 79\frac{1}{2}°$; angles variable, Ussing[1]. Usually in disseminated grains, or aggregations of grains.

Cleavage not distinct. Fracture subconchoidal. H. = 7·5. G. = 3·42–3·48; 3·486 Ussing. Luster vitreous. Color pale blue or green. Translucent. Pleochroic: $\mathfrak{b} = \mathfrak{c}$ blue, $\mathfrak{a}$ colorless. Optically −. Ax. pl. ∥ *b*. $Bx_a \wedge \dot{c} = -71°$ or $\mathfrak{c} \wedge 001 = +8\frac{1}{2}°$. Axial angles, Ussing[1]:

$$2K_{a.y} = 68°\,50' \qquad 2K_{o.y} = 111°\,13' \qquad \therefore\ 2V_{a.y} = 68°\,49' \qquad \beta_y = 1·712$$

$$\alpha_r = 1·7055 \qquad \beta_r = 1·7088 \qquad \nu_r = 1·7112$$

Also, Dx., $2H_{a.r} = 77°\,50'$ $2H_{a.bl} = 79°\,0'$ $\alpha_r = 1·705$ $\beta_r = 1·709$ $\gamma_r = 1·711$

$$2H_{a.r} = 83°\,29' \qquad 2H_{a.y} = 83°\,55' \qquad 2H_{a.gr} = 84°\,34'$$

**Comp.**—$Mg_5Al_{12}Si_2O_{27}$ or $5MgO.6Al_2O_3.2SiO_2$ = Silica 12·9, alumina 65·7, magnesia 21·4 = 100.

**Anal.**—1, Damour, Bull. G. Soc., **6**. 315, 1849. 2, Lorenzen, Medd. Grönl., **7**, 1884. 3, Ussing, Öfv. Ak. Stockh., **46**, 17, 1889. Also Schluttig, Inaug. Diss., Leipzig, 22, 1884, cf. Zs. Kr., **13**, 74.

| | | $SiO_2$ | $Al_2O_3$ | FeO | MgO |
|---|---|---|---|---|---|
| 1. | G. = 3·473 | 14·86 | 63·25 | 2·00 | 19·28 = 99·39 |
| 2. | G. = 3·46 | 12·95 | 64·44 | 1·66 | 19·83 ign. 0·34 = 99·22 |
| 3. | G. = 3·486 | 12·83 | 65·29 | 0·65 | 21·40 $Fe_2O_3$ 0·93 = 100·10 |

**Pyr., etc.**—B.B. alone and with borax infusible, unaltered.

**Obs.**—Associated with mica, anthophyllite, and amphibole at Fiskernäs in south-western Greenland. The name alludes to the sapphire color.

**Ref.**—[1] Öfv. Ak. Stockh., **46**, 17, 1889, and Zs. Kr., **15**, 598, 1889. Dx., Min., **1**, 462, 1862, **2**, xlii, 1874.

## APPENDIX TO ANHYDROUS SILICATES.

**Barylite** *C. W. Blomstrand*, G. För. Förh., 3, 128, 1876. Barylith.

In groups of prismatic crystals, more or less tabular in habit. Two distinct cleavages forming an angle of about 84°. H. = 7. G. = 4·03. Luster greasy. Colorless. Semi-transparent. Composition.—$Ba_4Al_4Si_7O_{24}$ or $4BaO.Al_2O_3.7SiO_2$ = Silica 34·0, alumina 16·5, baryta 49·5 = 100. Analysis:

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | BaO | PbO | CaO | MgO | CuO | $Bi_2O_3$ | ign. |
|---|---|---|---|---|---|---|---|---|---|---|
| $\frac{2}{3}$ | 34·36 | 16·02 | 0·98 | 46·23 | 0·93 | 0·68 | 0·27 | 0·09 | 0·19 | 0·15 = 99·90 |

B.B. infusible; not attacked by acid. Named from βαρύς, *heavy*, and λίθος, *stone*. Occurs with hedyphane in crystalline limestone at Långban, in Wermland, Sweden.

**Hypochlorite.** Sogenannter Grüneisenerde von Schneeberg, Hypochlorit, *Schüler*, Schw. J., **66**, 41, 1832, Dissert. de Ferro ochr., etc., Jena, 1832.

Bismutoferrite *Frenzel*, J. pr. Ch., **4**, 355, 1871, Jb. Min., 516, 1872.

**Hypochlorite** was described as minute crystalline; also earthy. Fracture even to flat conchoidal. Brittle. H. = 6. Luster vitreous, feeble. Color green. Streak light green. Analysis.—Schüler:

$SiO_2$ 50·24 $Al_2O_3$ 14·65 $Bi_2O_3$ 13·03 FeO 10·54 $P_2O_5$ 9·62 Mn *tr.*

In minute crystals and grains, or massive and earthy, with native bismuth and cobalt ores, at Schneeberg, Johanngeorgenstadt, and Bräunsdorf, in Saxony. Also reported from Ullersreuth, Voigtland, in a bed of limonite. Named from ὑπόχλωρος on account of its green chlorite-like color. Beyond doubt a mixture.

**Bismutoferrite** of Frenzel is a supposed bismuth-iron silicate in part mixed with the hypochlorite ("wismuth-hypochlorit") of Schneeberg. G. = 4·47. Two analyses gave:

| $SiO_2$ | $Bi_2O_3$ | $Fe_2O_3$ | |
|---|---|---|---|
| 23·08 | 43·26 | 33·33 | = 99·67 |
| 24·05 | 42·83 | 33·12 | = 100 |

An "antimony-hypochlorite" is also said to occur at Schneeberg.

**Monzonite** *F. v. Kobell*, Ber. Ak. München, 1, 162, 1871.

Compact. Fracture splintery to subconchoidal. H. = 6. G. = 3. Color light grayish green. Translucent on thin edges. Resembles green hornstone. Analysis, Kobell, l. c.:

| $SiO_2$ | $Al_2O_3$ | FeO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 52·60 | 17·10 | 9·00 | 2·10 | 9·65 | 6·60 | 1·90 | 1·50 = 100·45 |

B.B. fuses at 3 to a lustrous grayish green glass. Not decomposed by acids before or after fusion. Found on Mt. Monzoni in the Fassathal, Tyrol.

**Neociano** *A. Scacchi*, Rend. Accad. Napoli, Jan., 1881. Neocyanite.

In very minute monoclinic crystals, tabular ∥ 010; these are terminated by two orthodomes *m* and *n*, making angles of 71° and 53° with *a* (100), front and back respectively. Color blue. Supposed to be an anhydrous copper silicate. B.B. fuses to a black glass. Easily decomposed by acids, with the separation of pulverulent silica. From fumaroles at Vesuvius, formed by sublimation, together with three other substances. One of these forms a white granular mass, G. = 2·287, probably silica. A second is a white asbestus-like material, containing lime; difficultly fusible, and decomposed only in boiling acid. The other forms yellowish brown crystals in six-sided rhombic plates; insoluble in acid.

**Ramosite** *N. W. Perry*, Eng. Mng. J., **37**, 140, Feb. 23, 1884; Trans. Am. Inst. Mining Eng., **12**, 628, 1884.

In pebbles in alluvium; compact. Fracture conchoidal. H. = 8–9. G. = 3·83. Color deep black. Opaque, translucent on thin edges. Luster vitreous. Analysis:

$SiO_2$ 46·32 $Fe_2O_3$ 13·00 $Al_2O_3$ 19·19 CaO 17·74 MgO 13·13 $MnO_2$ *tr.* = 99·38.

From Ramos, San Luis Potosi, Mexico. The description obviously needs revision; it may prove to be simply a kind of garnet.

**Sphenoclase.** Sphenoklas *F. von Kobell*, J. pr. Ch., **91**, 348, 1864.

Massive, with faint indications of a foliated structure. Fracture splintery. H. = 5·5–6. G. = 3·2. Luster feeble. Color pale grayish yellow. Subtranslucent. Comp.—Perhaps $6RO.Al_2O_3.6SiO_2$ Rg., but needs confirmation. Analysis.—Kbl.:

$SiO_2$ 46·08 $Al_2O_3$ 13·04 FeO 4·77 MnO 3·23 MgO 6·25 CaO 26·50 = 99·87

B.B. fuses at 3 to a greenish glass. Slightly attacked by acids; but after heating, easily decomposed with gelatinization by hydrochloric acid.

From Gjellebäk in Norway, with wollastonite and the so-called edelforsite, forming thin layers of varying thickness in a bluish granular limestone. Named from σφήν, *a wedge*, and κλάσις, *fracture*, it breaking into wedge-shaped pieces.

## B. Hydrous Silicates.

The HYDROUS SILICATES include chiefly the true hydrous compounds, that is, those which contain water of crystallization, like the zeolites; also the hydrous amorphous species, as the clays, etc. There are also included certain species—as the Micas, Talc, Kaolinite—which, while they yield water upon ignition, are without doubt to be taken as acid or basic metasilicates, orthosilicates, etc. Their relation, however, is so close to other true hydrous species that it appears more natural to include them here than to have placed them in the preceding chapter with other acid and basic salts. Finally, some species are referred here about whose chemical constitution and the part played by the water present there is still much doubt.

The divisions of the Hydrous Silicates recognized are as follows:

### I. Zeolite Division.

**1. Introductory Subdivision.**
**2. Zeolites.**

### II. Mica Division.

**1. Mica Group.**
**2. Clintonite Group.**
**3. Chlorite Group.**

### III. Serpentine and Talc Division.

Chiefly hydrous Silicates of Magnesium.

### IV. Kaolin Division.

Chiefly hydrous Silicates of Aluminium; for the most part belonging to the group of the clays.

### V. Concluding Division.

Species not included in the preceding divisions; chiefly silicates of the heavy metals, iron, manganese, etc.

---

### I. Zeolite Division.

#### 1. Introductory Subdivision.

Of the species here included, several, while not strictly ZEOLITES, are closely related to them in composition and method of occurrence.

431. **Inesite** $2(\mathrm{Mn},\mathrm{Ca})\mathrm{SiO}_3 + \dot{\mathrm{H}}_2\mathrm{O}$ Triclinic
$\breve{a}:\bar{b}:\acute{c} = 0{\cdot}9753:1:1{\cdot}3208$ $\alpha = 92° 18'$ $\beta = 132° 56'$ $\gamma = 93° 51'$

$\grave{a}:\bar{b}:\acute{c}$ $\beta$
432. **Ganophyllite** $\mathrm{Mn}_7\mathrm{Al}_2\mathrm{Si}_8\mathrm{O}_{26}.6\mathrm{H}_2\mathrm{O}$ Monoclinic $0{\cdot}413:1:1{\cdot}831$ 86° 39'

---

433. **Okenite** $\mathrm{H}_2\mathrm{Ca}(\mathrm{SiO}_3)_2 + \mathrm{H}_2\mathrm{O}$ Orthorhombic?
434. **Gyrolite** $\mathrm{H}_2\mathrm{Ca}_2(\mathrm{SiO}_3)_3 + \mathrm{H}_2\mathrm{O}$
435. **Apophyllite** $\mathrm{H}_7\mathrm{KCa}_4(\mathrm{SiO}_3)_8 + 4\tfrac{1}{2}\mathrm{H}_2\mathrm{O}$ Tetragonal $\acute{c} = 1{\cdot}2515$

**431. INESITE.** *A. Schneider*, Jb., Preuss. G. Landesanst. for 1887, p. 472 (1888); Zs. G. Ges., 39, 829, 1888. Rhodotilit *G. Flink*, Öfv. Ak. Stockh., 45, 571, 1888, 46, 12, 1889.

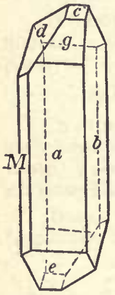
Triclinic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}975266 : 1 : 1{\cdot}32078$; $\alpha = 92° 18' 12''$, $\beta = 132° 55' 54''$, $\gamma = 93° 50' 42''$ Scheibe[1].

$100 \wedge 010 = {}^*82° 35'$, $100 \wedge 001 = 46° 41' 32''$, $010 \wedge 001 = 83° 14' 59''$.

**Forms:** *a* (100, $i\text{-}\bar{i}$), *b* (010, $i\text{-}\breve{i}$), *c* (001, *O*), *M* ($1\bar{1}0$, $'I$), *l* (101, $'1\text{-}\bar{i}'$), *g* (201, $'2\text{-}\bar{i}'$), *e* ($\bar{1}01$, $,1\text{-}\bar{i},$), *d* ($0\bar{1}1$, $'1\text{-}\breve{i}$), *o* (532, $,\tfrac{5}{2}\text{-}\tfrac{5}{3}$), *i* ($\bar{7}47$, $,1\text{-}\tfrac{7}{4}$)?.

$aM = 37° 59'$ $cg = 34° 36\tfrac{1}{2}'$ $ce = 85° 57\tfrac{1}{2}'$ $ad = {}^*64° 37'$
$b'M = 59° 26'$ $al = 19° 36\tfrac{3}{4}'$ $a'e = {}^*47° 21'$ $b'd = {}^*49° 23'$
$cl = 27° 4\tfrac{3}{4}'$ $ag = 12° 5'$ $cd = 47° 22'$ $be = {}^*93° 20'$

Crystals small, prismatic in habit. Usually in fibrous masses; often radiated and spherulitic.



*Inesite*, Scheibe.

Cleavage: *b* perfect; *a* less so. Fracture uneven. Brittle. H.=6. G. = 3·0295 Flink. Luster vitreous. Color rose-red to flesh-red; becoming colorless on exposure. Streak white. Pleochroism distinct but feeble.

Optically —. Extinction-direction on *a* (100) inclined to edge *a/b*, 12° to the left below; on *b* (010) inclined 60½° above behind. $Bx_a$ not quite ⊥ *b*. Axial angles (Adams polariscope, with $n_y = 1{\cdot}7782$ Na for the glass) measured on cleavage fragments ∥ *b*:

$2G_{a.r} = 64° 0'$ Li $2G_{a.y} = 63° 28'$ Na $2G_{a.gr} = 62° 51'$ Tl.

**Comp.**—$2(Mn,Ca)SiO_3 + H_2O$ = Silica 43·8, manganese protoxide 41·4, lime 8·2, water 6·6 = 100. Here Mn : Ca = 4 : 1.

**Anal.**—1, Bärwald, quoted by Schneider. 2, Flink, l. c.

| | $SiO_2$ | MnO | FeO | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. *Inesite* | 43·92 | 37·87 | 0·69 | 8·40 | 0·33 | 9·22 | $Al_2O_3$ 0·29 = 100·72 |
| 2. *Rhodotilite* | 43·67 | 37·04 | 1·11 | 9·38 | 0·15 | 7·17 | PbO 0·77 = 99·29 |

Of the water Bärwald found that 4·54 p. c. was lost at 110°, 0·48 at 200°, 2·23 at 300°, 0·62 at 440°, 1·35 upon ignition; total 9·22.

**Pyr.**—Gives off water in the closed tube and turns brown. Reacts for manganese with the fluxes. Soluble in acids, but not after ignition.

*Inesite* occurs at the manganese mines at Nanzenbach, northeast of Dillenburg, Germany. The manganese ores occur at the contact between clay slate and diabase, and the inesite is found with a manganesian calcite in cavities of a dark brown hydrous manganese silicate, allied to stratopeite (see p. 704). The crystals are embedded in calcite. Named from ἴνες, *flesh fibers*, in allusion to the color and structure.

*Rhodotilite* occurs filling cavities of calcite crystals, with rhodonite, garnet, etc., at the Harstig mine, Pajsberg, Wermland, Sweden. Named from ρόδον, *rose*, τίλος, *fiber*.

As shown by Flink (1889) the two minerals, though independently described, are without doubt identical, and the descriptions agree in almost every particular. The formula provisionally accepted is that of Flink. Schneider suggested $(Mn,Ca)(MnOH)_2Si_3O_8 + H_2O$.

**Ref.**—[1] Quoted by Schneider, l. c.

**432. GANOPHYLLITE.** *A. Hamberg*, G. För. Förh., 12, 586, 1890.

Monoclinic. Axes $\grave{a} : \bar{b} : \dot{c} = 0{\cdot}4130 : 1 : 1{\cdot}8309$; $\beta = 86° 39'$ Hamberg.
$100 \wedge 110 = 22° 24\tfrac{1}{2}'$, $001 \wedge 101 = 74° 7\tfrac{1}{2}'$, $001 \wedge 011 = {}^*61° 19'$.

**Forms:** *b* (010, $i\text{-}\grave{i}$), *c* (001, *O*), *m* (110, *I*), *e* (011, $1\text{-}\grave{i}$).

Angles: $mm''' = {}^*44° 49'$, $ee' = 122° 38'$, $cm = {}^*86° 54'$, $me = 88° 23\tfrac{1}{2}'$. The measurements are only approximate and hence the axial ratio cannot be regarded as highly accurate.

In crystals up to an inch in length, habit short prismatic, terminated by *c* and the acute clinodome *e* (011). Faces *m* and *e* dull, striated ∥ *c*. Also foliated, micaceous.

Cleavage: basal, perfect; resembling mica. Percussion-figure on cleavage fragment a six-rayed star; one ray ∥ edge *b/c*, the others inclined approximately

60° and hence not ‖ edge *c*/*m*. H. = 4–4·5. G. = 2·84. Luster vitreous, brilliant. Color brown.

Pleochroism distinct in sections ‖ ć: $\mathfrak{c}$ (= b̍) and $\mathfrak{b}$ (= à) colorless, $\mathfrak{a}$ (= ć) yellow-brown. Optically –. Ax. pl. ⊥ *b*. $Bx_a \perp c$; hence a cleavage fragment gives the axial figures. Axial angles:

$2E_r = 41° 19'$ Li    $\beta_r = 1·7250$   ∴ $2V_r = 23° 36'$
$2E_y = 41° 53'$ Na    $\beta_y = 1·7287$   ∴ $2V_y = 23° 52'$
Also $\gamma_r = 1·7264$  $\gamma_y = 1·7287$  ∴ (with 2E) $\alpha_r = 1·6941$  $\alpha_y = 1·7046$

**Comp.**—$6H_2O.7MnO.Al_2O_3.8SiO_2$ = Silica 40·5, alumina 8·6, manganese protoxide 41·8, water 9·1 = 100.

**Anal.**—Hamberg, l. c.

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| $\frac{2}{2}$ 39·67 | 7·95 | 0·90 | 35·15 | 1·11 | 0·20 | 2·70 | 2·18 | 9·79 $Li_2O$ *tr.*, PbO? 0·20 = 99·85 |

Most of the water goes off at 100° in a vacuum, if sufficient time is allowed, but with diminishing rapidity; it is largely reabsorbed in moist air. Hence it is somewhat analogous in behavior to the zeolites, so that the author calls it a *mangan-zeolite*. Physically it has some resemblance to the micas.

**Pyr.**—Reacts for manganese with the fluxes. Dissolves readily in strong acids, but becomes nearly insoluble after ignition.

**Obs.**—Occurs at the Harstig mine near Pajsberg, Wermland, Sweden, embedded in calcite, also implanted upon rhodonite and sometimes covered with caryophilite, barite, and native lead; again associated with garnet, manganophyllite, and pyrophanite.

Named from γάνος, *luster*, φύλλον, *leaf*, in allusion to the high luster on the cleavage laminæ.

---

433. **OKENITE.** Okenit *v. Kobell*, Kastner's Arch., **14**, 333, 1828. Dysclasite *Connel*, Ed. Phil. J., **17**, 198, 1834. Bordite *Adam*, Dufr. Min., **4**, 697, 1859.

Orthorhombic? Prismatic angle 57° 41′ Breith. Composed of a congeries of minute interlacing acicular crystals. Commonly fibrous; also compact.

Cleavage in traces. H. = 4·5–5. G. = 2·28, okenite, Kbl.; 2·362, dysclasite, Connel. Luster subpearly. Color white, with a shade of yellow or blue; often yellow by reflected light, and blue by transmitted. Frequently opalescent. Subtransparent to subtranslucent. Optically –. Ax. pl. ‖ *b* (010), the needles being elongated ‖ ć. Bx ⊥ *a* (100). Axial angle large. $\gamma - \alpha = 0·091$ Lcx.[1]

**Comp.**—$H_2CaSi_2O_6 + H_2O$ or $2H_2O.CaO.2SiO_2$ = Silica 56·6, lime 26·4, water 17·0 = 100.

**Anal.**—1, von Kobell, l. c. 2, Hauer, Jb. G. Reichs., **5**, 190, 1854. 3, Connel, l. c. 4, Adam, l. c. 5, Haughton, J. G. Soc. Ireland, **2**, 114, 1868. 6, Darapsky, Vh. Ver. Santiago, No. 6, p. 248, 1888 (read May 18, 1886).

| | | $SiO_2$ | CaO | $H_2O$ |
|---|---|---|---|---|
| 1. Disco | | 55·64 | 26·59 | 17·00 $Al_2O_3$,$Fe_2O_3$ 0·53, $K_2O$ *tr.* = 99·76 |
| 2. “ | | $\frac{2}{2}$ 54·81 | 27·23 | 18·04 = 100·08 [$Na_2O$ 0·44 = 100·44 |
| 3. Stromö, *Dysclasite* | G. = 2·362 | 57·69 | 26·83 | 14·71 $Fe_2O_3$ 0·32, $Mn_2O_3$ 0·22, $K_2O$ 0·23, |
| 4. Bordö, *Bordite* | G. = 2·33 | 56·92 | 25·14 | 14·19 $Al_2O_3$ 0·67, $Na_2O$ 1·04 = 97·96 |
| 5. Poona | | 54·24 | 27·44 | 17·04 $Na_2O$ 0·07 = 98·79 |
| 6. Rio Putagan, Chili | | 54·60 | 29·52 | 15·03 MgO *tr.*, $Na_2O$ 1·06 = 100·21 |

**Pyr., etc.**—In the closed tube yields water. B.B. alone becomes opaque and white, and fuses to a glass. Effervesces with soda, and fuses to a subtransparent glass, which is milk-white on cooling; with borax forms a transparent colorless glass. Gelatinizes readily in hydrochloric acid.

**Obs.**—Occurs in basalt or related eruptive rocks. Found at the Färöer (*bordite*); in Iceland; on the island of Disco, Greenland; in amygdaloidal basalt at Poona, near Bombay, India. On lava of Rio Putagan, Chili.

**Artif.**—A crystallized silicate near okenite, but containing some alkalies ($Na_2O$ 3·3, $K_2O$ 2·2) replacing the lime, has been obtained by A. de Schulten, Bull. Soc. Min., **5**, 92, 1882. Cf. also Doelter (Jb. Min., **1**, 123, 1890), who obtained okenite by recrystallization in carbonated water in a sealed tube.

**Ref.**—[1] Bull. Soc. Min., **8**, 341, 1885; **10**, 152, 1887.

**434. GYROLITE.** Gurolite *Anderson*, Phil. Mag., 1, 111, 1851.

In concretions, lamellar-radiate in structure.

H. = 3–4. G. not given. Luster vitreous to pearly. Color white. Translucent, becoming opaque. Optically uniaxial, negative. Double refraction rather strong, Dx.[1]

**Comp.**—$H_2Ca_2Si_3O_9 + H_2O$ or $3H_2O.2CaO.3SiO_2$ = Silica 52·1, lime 32·3, water 15·6 = 100.

**Anal.**—1, Anderson, l. c. 2, How, Am. J. Sc., **32**, 13, 1861. 3, Clarke, ib., **38**, 128, 1889.

| | $SiO_2$ | $Al_2O_3$ | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ |

[a] Incl. $Fe_2O_3$.

**Pyr., etc.**—In a closed tube yields water, intumesces, and separates into thin scales. B.B. swells up and fuses with difficulty to an opaque enamel.

**Obs.**—From the Isle of Skye, with stilbite, laumontite, etc. In India from the railway cuttings between Bombay and Poona; also from the Treshinish Islands (Heddle, but cf. okenite, anal. 5). Reported also from the Färöer and from Greenland.

With the apophyllite of New Almaden, California, in fibrous layers between the wall of the vein and the apophyllite. Also N. Scotia, 25 m. S.W. of C. Blomidon, between Margaretville and Port George, on apophyllite.

According to How, gyrolite is formed from apophyllite, with which it often occurs.

**Ref.**—[1] Dx., N. R., 13, 1867, Min., 2, xxi, 1874.

Heddle obtained thin six-sided plates, resembling heulandite, with plane angles 128° 45′ and 128° 55′, and he infers a similar form. Min. Mag., **8**, 272, 1889.

**435. APOPHYLLITE.** Zeolith von Hellesta *C. Rinman*, Ak. H. Stockh., 82, 1784. Zeolithus lamellaris major *Müller*, De Zeolithis Suecicis, 32, 1791. Ichthyophthalmite (fr. 4.

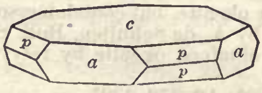

Figs. 1-3, Common forms. 4, L. Superior. 5, Utö, Sweden, after [illegible]auf.

On the apophyllite from the Seisser Alp, Tyrol, Ploner[7] has determined the following forms, many of which, however, are merely vicinal planes. Of these several had been earlier given by Rumpf, viz., 9·9·10, 24·24·25, 51·51·50, 108, 106.

1·0·60, 1·0·40, 1·0·30, 1·0·24, 1·0·20, 1·0·18, 1·0·14, 1·0·13, 1·0·12, 1·0·11, 2·0·21, 1·0·10, 2·0·19, 109, 108, 3·0·22, 107, 2·0·13, 3·0·19, 106, 3·0·17, 2·0·11, 3·0·16, 4·0·21, 3·0·14, 209, 104, 3·0·10, 103, 307, 504, 302.

1·1·54, 1·1·45, 1·1·36, 1·1·27, 1·1·18, 119, 335, 445, 556, 667, 778, 889, 9·9·10, 10·10·11, 11·11·12, 13·13·14, 17·17·18, 24·24·25, 50·50·51, 51·51·50, 25·25·24, 443, 332, 553, 221, 441, 551.

13·4·4, 311, 20·7·7, 522, 12·5·5, 744, 855, 322, 755, 433, 544, 655, 766.

21·7·3, 15·5·3, 12·4·3, 623, 313.

$ay$ = 18° 26′
$vv'$ = 19° 46′
$ss'$ = 44° 3½′
$ee'$ = 67° 4′
$vv''$ = 28° 6′
$ss''$ = 64° 4′
$ee''$ = 102° 45′

$dd'$ = 27° 18′
$zz'$ = 42° 7′
$pp'$ = 76° 0′
$xx''$ = 20° 4′
$dd''$ = 38° 59′
$\phi\phi''$ = 53° 39′

$zz''$ = 61° 5′
$\chi\chi''$ = 99° 26′
$pp''$ = 121° 4′
$cp$ = *60° 32′
$ap$ = 52° 0′
$a\rho$ = 19° 45′

$a\alpha$ = 23° 6′
$a\sigma$ = 32° 37′
$a\tau$ = 87° 31½′
$\rho\rho^{vii}$ = 36° 34′
$\alpha\alpha^{vii}$ = 35° 42½′
$\sigma\sigma^{vii}$ = 49° 49′

Twins: tw. pl. *p*, rare[6]. Habit varied; in square prisms (*a*) usually short and terminated by *c* or by *cp*, and then resembling a cube or cubo-octahedron; also acute pyramidal (*p*) with or without *c* and *a*; less often thin tabular ‖ *c*. Faces *c* often rough; *a* bright but vertically striated; *p* more or less uneven. Also massive and lamellar; rarely concentric radiated.

Cleavage: *c* highly perfect; *m* less so. Fracture uneven. Brittle. H. = 4·5–5. G. = 2·3–2·4. Luster of *c* pearly; of other faces vitreous. Color white, or grayish; occasionally with a greenish, yellowish, or rose-red tint, flesh-red. Transparent; rarely nearly opaque. Double refraction weak; usually +, also −. Often shows anomalous optical characters, cf. Mld.[9] Indices:

$\omega_r = 1·5309$ Li $\epsilon_r = 1·5332$ $\omega_y = 1·5337$ Na $\epsilon_y = 1·5356$ Luedecke[8].

A division of a basal section into biaxial parts with varying optical orientation is common (cf. Mld., Klein, *et al.*); thus there may be a central diagonal square and four lateral sectors bounded by lines parallel to the axes, and sometimes four others between these last, corresponding in position to the planes *e* (101).

Doelter found that apophyllite became uniaxial at about 260° C., the temperature at which it loses its water of crystallization.

**Var.**—1. *Ordinary.* Usually in crystals, as above described; the pearly basal cleavage is a conspicuous character. G. = 2·335, Iceland, Haid.; 2·359, Thomson.

Haüy's *Mesotype épointée* was an Iceland variety; Fuchs and Gehlen in 1816 ascertained its identity with apophyllite.

The name *Oxhaverite* was applied to a pale green crystal found in petrified wood at the Oxhaver Springs, near Husavic in Iceland. *Albine* of Werner (named from *albus, white*) is in small nearly cubic crystals, opaque white in color, from Aussig, Bohemia; it is partly decomposed and consists largely of calcite. *Xylochlore*, from Iceland, is olive-green, and has G. = 2·290; it owes its color to the presence of a little iron.

*Tesselite*, from the Färöer, is a cubical variety, exhibiting a tessellated structure in polarized light.

*Leucocyclite*, when sections parallel to the base are examined in polarized light, shows a black cross with rings that are alternately white and violet-black (whence the name from λευκός, *white*, and κύκλος, *circle*), instead of the ordinary colored rings—a peculiarity observed in crystals from the Seisser Alp, Andreasberg (part of those of this locality), Skye, Färöer, Iceland, Utö, and Poona in India. The above are optically +. Some crystals from Utö and Cziklowa, similarly examined, exhibit a black cross on a deep violet ground, and are optically −. These different optical phenomena may be presented by contiguous plates of the same crystal, cf. Dx.

**Comp.**—$H_7KCa_4(SiO_3)_8 + 4\frac{1}{2}H_2O$ or $K_2O.8CaO.16SiO_2.16H_2O$. = Silica 53·7, lime 25·0, potash 5·2, water 16·1 = 100. A small amount of fluorine replaces part of the oxygen.

The above formula (Rg., Groth) differs but little from $H_2CaSi_2O_6 + H_2O$, in which potassium replaces part of the basic hydrogen. The form often accepted, $H_2(Ca,K)Si_2O_6 + H_2O$, corresponds less well with the analyses.

Rg. writes the formula, accepted above, $4(H_2CaSi_2O_6 + H_2O) + KF$.

[a] Another determination gave 1·65 F.

Rg. found that no water was lost over sulphuric acid, nor at 100°; the first is expelled at 200°, and at 260° the loss corresponds to about 4 p. c. which is reabsorbed and is hence regarded as water of crystallization. Doelter gives, as follows: Loss of water at 240°, after 2 hours, 8·04 p. c.; after 4 hours heating at a red heat 9·20; for Fassathal at 260° after 2 hours, 9·59 p. c., which was gradually absorbed again on exposure to moist air, but only after 3586 hours. These determinations by Unterweissacher, Jb. Min., **1**, 120, 1890. Hersch (l. c.) obtained the following results, after 2 hours heating, in each case:

| Temp. | 100° | 160° | 200° | 240° | 275° | 300° | red ht. | |
|---|---|---|---|---|---|---|---|---|
| $H_2O$ | 0·11 | 0·38 | 0·77 | 2·03 | 9·08 | 9·91 | 16·61 | p. c. |

**Pyr., etc.**—In the closed tube exfoliates, whitens, and yields water, which reacts acid. In the open tube, when fused with salt of phosphorus, gives a fluorine reaction. B.B. exfoliates, colors the flame violet (potash), and fuses to a white vesicular enamel. F. = 1·5 (Kobell). Decomposed by hydrochloric acid, with separation of slimy silica.

**Obs.**—Occurs commonly as a secondary mineral in basalt and related rocks, with various zeolites, also datolite, pectolite, calcite; also occasionally in cavities in granite, gneiss, etc. Greenland, Iceland, the Färöer Islands, and British India afford fine specimens of apophyllite in amygdaloid. The Indian mineral is of unrivaled size and beauty, the crystals sometimes 3 to 4 inches across, often associated with salmon-pink stilbite, etc. It has been found in connection with the Deccan trap area, at Poona near Bombay during the sinking of wells and in the Western Ghâts, obtained abundantly during the construction of the Great Indian Peninsular Railway (Mallet). Also occurs at Andreasberg, sometimes of a delicate pink, in silver veins, traversing slate; Radauthal in the Harz; Montecchio Maggiore, Italy; at Orawitza, Cziklowa, and Szaska in Hungary, associated with wollastonite; in Fifeshire, with magnetic iron; at Puy de la Piquette in Auvergne, in a Tertiary limestone, near intruded basaltic rocks; at Finbo, Utö, and Hällesta, Sweden; in Tyrol, on the Seisser Alp; also the Fassathal; near Nerchinsk, Siberia; in Australia; Guanajuato, Mexico, often of a beautiful pink color implanted upon amethyst.

In the U. S., large crystals occur at Bergen Hill, N. J., associated with analcite, pectolite, stilbite, datolite, etc., some of them 3 inches across. It is also found at Gin Cove, near Perry, Maine, with prehnite and analcite in amygdaloid; in N. York, at the Tilly Foster iron mine, Brewster, but rare; in Penn., at the French Creek mines, Chester Co., also at Fritz Is., in the Schuylkill; at the Cliff mine, Lake Superior region; Table Mt. near Golden, Col.; in California, in large crystals at the mercury mines of New Almaden with bitumen, and often stained brown by it.

It has been found at Peter's Point and Partridge Island, in the Basin of Mines, Nova Scotia, both massive and crystallized, presenting white, reddish, and greenish colors, and associated with laumontite, thomsonite, and other zeolites; also at Chute's cove, Cape d'Or, Isle Haute, Swan's Creek, and Cape Blomidon.

Apophyllite was so named by Haüy in allusion to its tendency to exfoliate under the blowpipe, from ἀπό and φύλλον, *a leaf*. Its whitish pearly aspect, resembling the eye of a fish after boiling, gave rise to the earlier name *Ichthyophthalmite*, from ἰχθύς, *fish*, ὀφθαλμός, *eye*.

**Alt.**—Occurs altered to pectolite near Tiexno on Monte Baldo, along with unchanged crystals. Altered apophyllite from Table Mt., near Golden, Colorado, has been analyzed by Hillebrand (l. c.); it is pearly-white in color with a finely foliated structure and forms the exterior of crystals which within are often perfectly fresh. The material (which lost water over sulphuric acid) after drying at 100° gave:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 67·96 | 8·48 | 1·04 | 5·47 | 0·53 | [0·74] | 1·23 | 14·55 | = 100 |

**Artif.**—Crystals have been obtained by Wöhler from heated waters, and he inferred that a temperature of 180° was necessary to the result. He stated that when heated in water to this temperature under a pressure of 10 to 12 atmospheres, it forms a solution which crystallizes on cooling. Pearly radiated crystals were formed by Becquerel through the action of a solution of potassium silicate on plates of calcium sulphate (gypsum). Daubrée has detected crystals of apophyllite in the Roman works at the hot springs of Plombières.

Also obtained by Doelter (l. c.) by recrystallization, the powdered mineral being digested for 3 weeks in a closed tube at 150°–160° with water containing carbon dioxide; minute tetragonal crystals were the result. Again from okenite by heating with potassium silicate and carbonated water at 200° for 30 days.

By the fusion of apophyllite and slow crystallization the hexagonal $CaSiO_3$ (p. 373) was obtained.

**Ref.**—[2] Min., 436, 1852; also accepted by Dx., Min., **1**, 125, 1862. [2] Cf. Lévy, Min. Heuland, **2**, 271, 1837; Schrauf, Ber. Ak. Wien, **62** (1), 700, 1870, Atlas XXI; Seligmann, Jb. Min., **1**, 140, 1880. Rumpf, who makes the species monoclinic, adds several forms mostly vicinal, Min. Mitth., **2**, 369, 1879; Ploner (ref. below) also adds many forms, chiefly vicinal; all of these are given above. Bgr. notes on the apophyllite from the islands of the Langesund fiord the probable forms: 1·0·12, 503, 326, 321, Zs. Kr., **16**, 644, 1890.

---

The following are imperfectly defined hydrous calcium silicates, several of them approximating to okenite and gyrolite.

CENTRALLASSITE *How*, Ed. N. Phil. J., **10**, 84, 1859; Phil. Mag., **1**, 128, 1876. Radiated massive, the fibers or columns lamellar and separable. Brittle. H. = 3·5; G. = 2·45–2·46. Luster pearly. Color white or yellowish white; thin laminæ transparent; graduating into an opaque white variety, subresinous in luster. The mineral was found in a nodule from amygdaloid, near Black Rock, Bay of Fundy, and constituted the portion between a thin outer layer, "*cerinite*," and an inner bluish mass, called "*cyanolite*." How obtained:

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 1. | $\frac{3}{2}$ $SiO_2$ 58·86 | $Al_2O_3$ 1·14 | CaO 27·91 | MgO 0·16 | $K_2O$ 0·59 | $H_2O$ 11·41 | = 100·07 |
| 2. | 54·72 | 2·19 | 31·53 | — | 0·76 | 11·58 | = 100·78 |

B.B. fuses easily, with spirting, to an opaque glass. It is near okenite in composition. Two analyses of the so-called *cyanolite* gave:

| | $SiO_2$ | $Al_2O_3$ | CaO | MgO | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| G. = 2·495 | 74·15 | 0·84 | 17·52 | *tr.* | 0·53 | 7·39 | = 100·43 |
| | 72·52 | 1·24 | 18·19 | *tr.* | 0·61 | 6·91 | = 99·47 |

Probably the same mineral with centrallassite, impure with much more silica; or it is chalcedony, impure with centrallassite. The name alludes to the color.

*Cerinite* gave: $SiO_2$ 58·13, $Al_2O_3$ 12·21, $Fe_2O_3$ 1·01, CaO 9·49, MgO 1·83, $K_2O$ 0·37, $H_2O$ 15·96 = 99·00.

XONOTLITE. Xonaltit *Rammelsberg*, Zs. G. Ges., **18**, 33, 1866. Xonotlit Min. Ch., 380, 1875.

Massive. Fracture splintery. Very hard. G. = 2·71–2·718. Color white to bluish gray; pink. Tough. Optically like okenite, Lcx. Comp.—Perhaps $4CaSiO_3 + H_2O$ = Silica 49·8, lime 46·4, water 3·8 = 100. Anal.—1, 2, Rg., l. c. 3, Heddle, Min. Mag., **5**, 4, 1882.

| | G. | $SiO_2$ | FeO | MnO | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. Mexico, *white* | 2·710 | 49·58 | 1·31 | 1·79 | 43·56 | — | 3·70 | = 99·94 |
| 2. " *gray* | 2·718 | 50·25 | 2·28 | | 43·92 | 0·19 | 4·07 | = 100·71 |
| 3. Scotland | 2·605 | 48·91 | 2·97 | 2·27 | 40·39 | 0·56 | 4·17 | $Al_2O_3$ 0·11, $K_2O$ 1·16, $Na_2O$ [0·22 = 100·76 |

Yields water. Decomposed by hydrochloric acid with separation of pulverulent silica. Occurs at Tetela de Xonotla, Mexico, in concentric layers, with apophyllite and bustamite.

Described by Heddle (l. c.) as occurring near Kilfinnichan, Loch Screden, Mull; at Gribon, opposite Oronsay, and on the north shore of Loch na Keal. It resembles a pink chalcedony and is closely associated with gyrolite.

**Tobermorite** *Heddle*, Min. Mag., 4, 119, 1880. Massive, fine granular. G. = 2·423. Color pale pinkish white. Translucent. Anal.—1, Tobermory; 2, north of Tobermory, toward Bloody Bay.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | | 46·51 | 2·40 | 1·14 | 1·85 | 33·40 | 0·47 | 1·45 | 0·36 | 12·61 | = 100·19 |
| 2. | G. = 2·423 | 46·62 | 3·90 | 0·66 | 1·08 | 33·98 | — | 0·57 | 0·89 | 12·11 | = 99·81 |

Occurs filling cavities in the rocks near Tobermory, Island of Mull. Near gyrolite.

**Chalcomorphite.** Chalkomorphit *Rath*, Pogg. Erg., 6, 376, 1873.

Hexagonal. Axis $\dot{c}$ = 1·9091, *cp* = *65° 36′. In minute acicular prisms with *c*, *m*, *p*; *pp′* = 54° 10½′. Cleavage: *c* distinct. H. = 5. G. = 2·54. Luster vitreous. Color white. Anal.—Rath, on 0·26 gr.

$SiO_2$ 25·4 $Al_2O_3$ 4·0 CaO 44·7 $H_2O$ (& $CO_2$) 16·4 loss (incl. $Na_2O$) 9·5 = 100

Gives water in the closed tube, becoming white and lusterless. B.B. fuses with difficulty on the edges, curling up like scolecite. Soluble in hydrochloric acid with the separation of gelatinous silica. From the Laacher See, also from Niedermendig in the Eifel, occurring in cavities in limestone inclusions in the lava.

**Plombierite** *Daubrée*, C. R., 46, 1088, 1858, Ann. Mines, 13, 244, 1858. A gelatinous substance which hardens in the open air, formed from the thermal waters of Plombières. It becomes, on hardening, opaque snow-white. It afforded after drying at 100° C.: $SiO_2$ 40·6, $Al_2O_3$ 1·3, CaO 34·1, $H_2O$ 23·2 = 99·2, corresponding to the hydrated calcium silicate: $CaSiO_3 + 2H_2O$ = Silica 39·5, lime 36·8, water 23·7 = 100.

Chabazite and apophyllite in fine crystals are other results of the action of the waters of Plombières on the brick and mortar of an old Roman aqueduct, besides hyalite, aragonite, and perhaps scolecite and harmotome.

**Louisite** *Honeymann*, Proc. Nova Scotia Inst. Nat. Sc., 5, 15, 1878. A transparent, glassy, leek-green mineral; streak white; fracture splintery. H. = 6·5. G. = 2·41. Gelatinizes with hydrochloric acid. An analysis by H. Louis gave: $SiO_2$ 63·74, $Al_2O_3$ 0·57, FeO 1·25, MnO *tr.*, CaO 17·27, MgO 0·38, $K_2O$ 3·38, $Na_2O$ 0·08, $H_2O$ 12·96 = 99·63. This corresponds, but only approximately, to $CaO.3SiO_2.2H_2O$, which requires Silica 66·2, lime 20·6, water 13·2 = 100.

It needs further examination, especially by the microscope, with reference to the possibility of admixed silica. Named for H. Louis, Esq., of Londonderry, N. S.

## 2. ZEOLITES.

The **Zeolites** form a family of well-defined hydrous silicates, closely related in composition, in conditions of formation, and hence in method of occurrence. They are often with right spoken of as analogous to the Feldspars, like which they are all silicates of aluminium with sodium and calcium chiefly, also rarely barium and strontium; magnesium, iron, etc., are absent or present only through impurity or alteration. Further, the composition in a number of cases corresponds to that of a hydrated feldspar; while fusion and slow recrystallization result in the formation from some of them of anorthite ($CaAl_2Si_2O_8$) or a calcium-albite ($CaAl_2Si_6O_{16}$) as shown by Doelter. The Zeolites do not, however, form a single group of species related in crystallization, like the Feldspars, but include a number of independent groups widely diverse in form and distinct in composition. A transition in composition between certain end compounds has been more or less well established in certain cases, but unlike the Feldspars, with these species calcium and sodium seem to replace one another and an increase in alkali does not go with an increase in silica.

Like other hydrous silicates they are characterized by inferior hardness, chiefly from 3·5 to 5·5, and the specific gravity is also lower than with corresponding anhydrous species, chiefly 2·0 to 2·4. Corresponding to these characters, they are rather readily decomposed by acids, many of them with gelatinization. The intumescence, B.B., which gives the name to the family (from ζεῖν, *to boil*, and λίθος, *stone*) is characteristic of a large part of the species.

The Zeolites are all secondary minerals, occurring most commonly in cavities and veins in basic igneous rocks, as basalt, amygdaloid, diabase, etc.; less frequently in granite, gneiss, etc. In these cases the lime, and in part the soda, has been chiefly yielded by the feldspar, the soda also by elæolite, sodalite, etc., potash by leucite, etc. The different species of the family are often associated together, and also with pectolite and apophyllite (sometimes included with the zeolites), datolite, prehnite and, further, calcite.

The constitution of the Zeolites, particularly with reference to the part played by the water, has been discussed by many authors. See Damour, Ann. Ch. Phys., **53**, 438–459, 1858. Malaguti and Durocher, Ann. Mines, **9**, 325, 1846. Rg., Min. Ch., 1860, 1875. Lemberg (artif.), Zs. G. Ges., **28**, 535 *et seq.*, 1876. Streng (chabazite group), Ber. Oberhess. Ges., **16**, 74–123, 1877. Fresenius (phillipsite group), Zs. Kr., **3**, 42, 1879. Jannasch (heulandite, etc.), Jb. Min., **2**, 269, 1882. Friedel and Sarasin, Bull. Soc. Ch., **42**, 593, 1884. Hersch, Inaug. Diss., Zürich, 1887. Doelter (artif.), Jb. Min., **1**, 118, 1890.

On the effect of loss of water upon the optical properties, see Rinne, Jb. Min., **2**, 17–38, 1887, and Ber. Ak. Berlin, 1163, 1890. Rinne shows that sections after having been heated until they became opaque may be made transparent again and suitable for optical examination by immersion in oil; important molecular changes are thus shown to accompany the loss of water, in some cases they serve to explain the anomalous optical characters often observed in natural crystals (cf. chabazite, analcite, etc.). See also Doelter, l. c., and other authors noted beyond. A summary of the optical relations of the various species, with reference to the means of distinguishing between them by the microscope, is given by Lcx., Bull. Soc. Min., **8**, 321 *et seq.*, 1885.

The species are arranged on the same method as the anhydrous silicates, first the highly acid species, Ptilolite and Mordenite, then the metasilicates, including much the larger part of the family, and finally the normal orthosilicates. For the most part the species fall in definite groups.

## Mordenite Group.

436. **Ptilolite** $(Ca,K_2,Na_2)Al_2Si_{10}O_{24} + 5H_2O$

437. **Mordenite** $(Ca,Na_2,K_2)Al_2Si_{10}O_{24} + 6\frac{2}{3}H_2O$ Monoclinic

$\grave{a} : \overset{|}{b} : \acute{c} = 0{\cdot}4010 : 1 : 0{\cdot}4279 \quad \beta = 88° 30'$

## Heulandite Group. Monoclinic.

| | | | $\grave{a} : \overset{\vert}{b} : \acute{c}$ | $\beta$ |
|---|---|---|---|---|
| 438. | **Heulandite** | $H_4CaAl_2(SiO_3)_6 + 3H_2O$ | 0·4035 : 1 : 0·4293 | 88° 34½′ |
| 439. | **Brewsterite** | $H_4(Sr,Ba,Ca)Al_2(SiO_3)_6 + 3H_2O$ | 0·4049 : 1 : 0·4204 | 86° 20′ |

| | | | | |
|---|---|---|---|---|
| 440. | **Epistilbite** | $H_4CaAl_2(SiO_3)_6 + 3H_2O$ | 0 5043 : 1 : 0·5801 | 54° 53′ |

## Phillipsite Group. Monoclinic.

| | | | $\grave{a} : \overset{\vert}{b} : \acute{c}$ | $\beta$ |
|---|---|---|---|---|
| 441. | **Phillipsite** | $(K_2,Ca)Al_2Si_4O_{12} + 4\frac{1}{2}H_2O$ | 0·7095 : 1 : 1·2563 | 55° 37′ |
| 442. | **Harmotome** | $H_2(K_2,Ba)Al_2Si_5O_{15} + 5H_2O$ | 0·7032 : 1 : 1·2310 | 55° 10′ |
| 443. | **Stilbite** | $(Na_2,Ca)Al_2Si_6O_{16} + 6H_2O$ | 0·7623 : 1 : 1·1940 | 50° 50′ |

444. **Gismondite** $CaAl_2(SiO_3)_4 + 4H_2O$? Monoclinic. Pseudotetragonal.

445. **Laumontite** $H_4CaAl_2Si_4O_{14} + 2H_2O$ Monoclinic.

$\grave{a} : \overset{|}{b} : \acute{c} = 1{\cdot}1451 : 1 : 0{\cdot}5906 \quad \beta = 68° 46'$

446. **Laubanite** $Ca_2Al_2(SiO_3)_5 + 6H_2O$

## Chabazite Group. Rhombohedral.

| | | | $rr'$ | $\dot{c}$ |
|---|---|---|---|---|
| 447. | **Chabazite** | $(Ca,Na_2)Al_2Si_4O_{12} + 6H_2O$, pt. | 85° 14′ | 1·0860 |
| 448. | **Gmelinite** | $(Na_2Ca)Al_2Si_4O_{12} + 6H_2O$ | 68° 8′ | 0·7345 or $\frac{3}{2}\dot{c} = 1·1017$ |
| 449. | **Levynite** | $CaAl_2Si_3O_{10} + 5H_2O$ | 73° 56′ | 0·8357 $\frac{4}{3}\dot{c} = 1·1143$ |

| | | | | |
|---|---|---|---|---|
| 450. | **Analcite** | $NaAl(SiO_3)_2 + H_2O$ | Isometric. | |
| 451. | **Faujasite** | $H_4Na_2CaAl_4(SiO_3)_{10} + 18H_2O$ | Isometric. | |
| 452. | **Edingtonite** | $BaAl_2Si_3O_{10} + 3H_2O$ | Tetragonal. | $\dot{c} = 0·6725$ |

## Natrolite Group. Orthorhombic and Monoclinic.

| | | | | |
|---|---|---|---|---|
| | | | $\breve{a} : \bar{b} : \dot{c}$ | |
| 453. | **Natrolite** | $Na_2Al_2Si_3O_{10} + 2H_2O$ | 0·9785 : 1 : 0·3536 | |
| | | | $\grave{a} : \bar{b} : \dot{c}$ | $\beta$ |
| 454. | **Scolecite** | $Ca(AlOH)_2(SiO_3)_3 + 2H_2O$ | 0·9764 : 1 : 0·3434 | 89° 18 |
| 455. | **Mesolite** | $\left\{\begin{matrix} Na_2Al_2Si_3O_{10} + 2H_2O \\ 2[CaAl_2Si_3O_{10} + 3H_2O] \end{matrix}\right.$ | | |

## Thomsonite Group.

| | | | | |
|---|---|---|---|---|
| | | | | $\breve{a} : \bar{b} : \dot{c}$ |
| 456. | **Thomsonite** | $(Na_2,Ca)Al_2(SiO_4)_2 + 2\frac{1}{2}H_2O$ | Orthorhombic. | 0·9932 : 1 : 1·0066 |
| 457. | **Hydronephelite** | $HNa_2Al_3(SiO_4)_3 + 3H_2O$ | Hexagonal. | |
| | Ranite | $(Na_2,Ca)Al_2(SiO_4)_2 + 2H_2O$ | | |

## Mordenite Group.

**436. PTILOLITE** *W. Cross* and *L. G. Eakins*, Am. J. Sc., **32**, 117, 1886.

In short capillary crystalline needles, aggregated in delicate tufts or forming loose spongy masses.

Cleavage perhaps basal. Luster vitreous. Colorless, white in the mass. Transparent. Extinction parallel.

**Comp.**—$RAl_2Si_{10}O_{24} + 5H_2O$ or $RO.Al_2O_3.10SiO_2.5H_2O$. Here $R = Ca : K_2 : Na_2 = 6 : 2 : 1$ approx., which requires: Silica 70·0, alumina 11·9, lime 4·4, potash 2·4, soda 0·8, water 10·5 = 100.

**Anal.**—Eakins. l. c. on air-dried material:

| $SiO_2$ | $Al_2O_3$ | CaO | $K_2O$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|
| 70·35 | 11·90 | 3·87 | 2·83 | 0·77 | 10·18 = 99·90 |

The loss of water beginning at 100° C. goes on steadily up to 300° or 350°, when all is expelled.

**Pyr., etc.**—Fuses B.B. to a clear glass. Gradually decomposed by sulphuric acid, but hardly acted upon by hydrochloric acid, even when boiling.

**Obs.**—Occurs upon a bluish chalcedony in cavities in a vesicular augite-andesyte which is found in fragments in the conglomerate beds of Green and Table mountains, Jefferson Co., Colorado.

Named from *πτίλον, wing, down,* in allusion to the light downy nature of the aggregates.

**437. MORDENITE.** *How*, J. Ch. Soc., **17**, 100, 1864.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 0·40099 : 1 : 0·42792$; $\beta = 88° 29\frac{3}{4}' = 001 \wedge 100$ Pirsson[1].

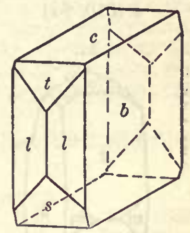
$100 \wedge 110 = 21° 50' 36''$, $001 \wedge 101 = 46° 3' 37''$, $001 \wedge 011 = 23° 9' 35''$.

**Forms:** *b* (010, *i*-ì), *c* (001, *O*), *l* (450, *i*-$\frac{5}{4}$), *t* (201, − 2-ī), *s* ($\bar{2}01$, 2-ī).

Angles: *ll'''* = 53° 14', *bl* = 63° 23' *ct* = *63° 40', *cs* = 66° 8', *ts'* = *50° 12', *lt* = 35° 46', *ls'* = * 36° 7'.

The form approximates very closely to that of heulandite (p. 574), if the occurring prism is made 450, as above.

In minute crystals tabular ∥ *b*, resembling heulandite in habit and angles. Crystals in groups by growth ∥ *b*; also radially arranged. In small hemispherical, reniform, or cylindrical concretions. Structure fibrous.



Wyoming, Pirsson.

Cleavage: *b* perfect. Fracture uneven. Brittle. H. = 3–4. G. = 2·08 How; 2·15 Pirsson. Luster vitreous; on *b* pearly; in fibrous forms highly silky. Color white, yellowish, or pinkish. Translucent on the edges. Ax. pl. and $\mathfrak{a} \perp b$. Double refraction weak. Extinction inclined about 15° to *à*, or $\mathfrak{c} \wedge \grave{c} = -73° 30'$. Axial angle large.

**Comp.**—$3RAl_2Si_{10}O_{24} + 20H_2O$ where $R = K_2 : Na_2 : Ca = 1 : 1 : 1$. Percentage composition: Silica 67·2, alumina 11·4, lime 2·1, soda 2·3, potash 3·5, water 13·5 = 100.

**Anal.**—1, How, l. c. 2, Pirsson, Am. J. Sc., **40**, 232, 1890.

| | | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. | ⅚ | 68·40 | 12·77 | 3·46 | 2·35[a] | — | 13·02 = 100 |
| 2. | | 66·40 | 11·17 | 1·94 | 2·27 | 3·58 | 13·31 $Fe_2O_3$ 0·57, MgO 0·17 = 99·41 |

[a] Incl. 0·09 to 0·23 $K_2O$.

The powdered mineral loses 3 to 6 p. c. after an hour's exposure to a temperature of 100°.

**Pyr.**—B B. fuses with some difficulty and without intumescence to a white enamel. Not perfectly decomposed by acids.

Obs.—Occurs near Morden, King's Co., Nova Scotia, in trap, with apophyllite, barite, and a prehnite-like mineral; at Peter's Point, eight miles west, with gyrolite. Also in western Wyoming near Hoodoo Mt., on the ridge forming the divide between Clark's Fork and the East Fork (Lamar R.) of the Yellowstone river; it occurs in cavities in a decomposed amygdaloidal basalt in crystals and in spherical concretions.

Named after the original locality in Nova Scotia.

Ref.—[1] Wyoming. Am. J. Sc., **40**, 232, 1890.

STEELEITE *How*, Min. Mag., **2**, 134, 1878. A partially altered mordenite, found as red or reddish pink, or chalk-white, balls, varying in size from one to two and a half inches in diameter, embedded in a red clay in cavities in trap. Also in other forms, closely associated with stilbite. In part soft and chalk-like; in part hard and unaltered. Gelatinizes with acids. Locality Cape Split, 13 miles west of Cape Blomidon, N. S. Named after the collector, Mr. Joseph Steele of Scot's Bay, N. S.

PSEUDONATROLITE *Grattarola*, Att. Soc. Tosc., **4**, 229, 1879; Boll. Com. G., 284, 1872. In minute, acicular crystals. H. = 5–6. Luster vitreous to pearly. Colorless, white in the mass. Extinction parallel.

Mean of three analyses:

$SiO_2$ 62·64 $Al_2O_3$ 14·76 CaO 8·54 MgO *tr.* Alk. 1·00 $H_2O$ 14·82 = 101·76.

B.B. fuses less readily than natrolite. Partially soluble in hydrochloric acid. From the granite of San Piero, Elba, where it occurs, associated with stilbite, in slender crystals showing six planes in the prismatic zone; they are not terminated, being attached at both extremities to the walls of the cavities in which they are found. The mineral was originally described by the author (1872) as natrolite, from which, however, he showed it to differ widely in composition; it needs further examination.

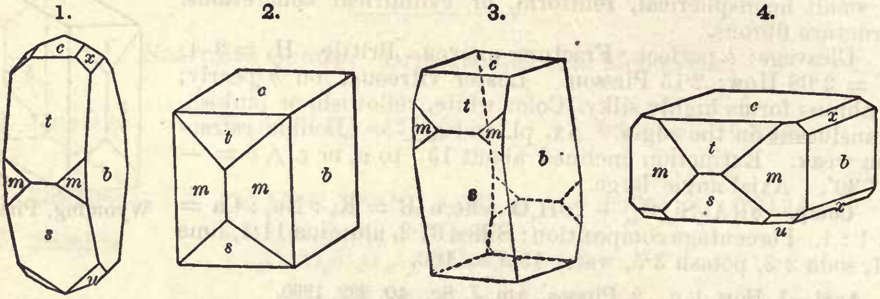
## Heulandite Group. Monoclinic.

**438. HEULANDITE.** Blättriger Zeolith *Meyer*, Beschaft. Ges. N. Fr. Berlin, **4**, 1779, *Hoffm.*, Bergm. J., 430, 1789. Blätter-Zeolith (var. of Z.) *Wern.*, 1800, Ludw. Min., 49, 1803 Stilbite pt., Stilbite anamorphique, *H.*, Tr., **3**, 1801. Euzeolith *Breith.*, Hoffm. Min., **4**, b, 40, 1818. Heulandite *Brooke*, Ed. Phil. J., **6**, 112, 1822. Lincolnite *Hitchcock*, Rep. G. Mass. 1833, 437, 1835, 662, 1841. Beaumontite *Lévy*, Inst., 455, 1839, and Ann. Mines, **17**, 610, 1840.

Monoclinic. Axes: $\grave{a} : \overset{|}{b} : \acute{c} = 0{\cdot}40347 : 1 : 0{\cdot}42929$; $\beta = 88^\circ\ 34\frac{1}{2}' = 001 \wedge 100$ Des Cloizeaux[1].

$100 \wedge 110 = 21^\circ\ 58'$, $001 \wedge 101 = 46^\circ\ 1\frac{1}{6}'$, $001 \wedge 011 = 23^\circ\ 13\frac{1}{3}'$.

**Forms**[2]: *c* (001, *O*) *t* (201, − 2-$\bar{i}$) *x* (021, 2-$\grave{i}$) *u* ($\bar{1}$11, 1)
*a* (100, *i*-$\bar{i}$) *m* (110, *I*) *s* ($\bar{2}$01, 2-$\bar{i}$) *z* (052, $\frac{5}{2}$-$\grave{i}$)? *v* ($\bar{2}$21, 2)[3]
*b* (010, *i*-$\grave{i}$)



Figs. 1, Campsie Hills, after Greg. 2, *Beaumontite*, Jones's Falls. 3, 4, Montecchio Maggiore, Artini.

| | | | |
|---|---|---|---|
| *mm'''* = *43° 56' | *xx'* = 81° 17' | *cu* = 49° 40½' | *vv* = 40° 28' |
| *ct* = *63° 40' | *cx* = 40° 38½' | *cv* = 67° 34 | *mt* = 32° 44' |
| *cs* = *66° 0' | *zz'* = 94° 2' | *uu'* = 33° 9' | *ms'* = 33° 7' |
| *ts* = 129° 40' | *cm* = 88° 41' | | |

Twins: tw. pl. *a*. Crystals sometimes flattened ∥ *b*, the surface of pearly luster; form often suggestive of the orthorhombic system, since the angles *cs* and *ct* differ but little. Crystals often made up of subindividuals in nearly parallel position. Faces usually undulating; *b* often deeply depressed, the orthodomes bright but striated ∥ *b*. Also in globular forms; granular.

Cleavage: *b* perfect. Fracture subconchoidal to uneven. Brittle. H. = 3·5–4. G. = 2·18–2·22. Luster of *b* strong pearly; of other faces vitreous. Color various shades of white, passing into red, gray, and brown. Streak white. Transparent to subtranslucent.

Optically +. Double refraction weak. Ax. pl. and $Bx_a \perp b$. Ax. pl. and $Bx_o$ for some localities nearly ∥ *c*; also for others, nearly ⊥ *c* in white light (Dx.). $Bx_o \wedge \acute{c} = +\ 57\frac{1}{2}^\circ$ Rinne, etc., see below. Dispersion $\rho < v$, when ax. pl. ∥ *c*; $\rho > v$, when ⊥ *c*; also crossed very strong; the ax. planes for red and blue inclined from 7° to 12°. Axial angle variable, from 0° to 92°; usually $2E_r = 52^\circ$, $2E_{bl} = 53^\circ$ Dx[4]. Also, Artini[4]:

| | | | |
|---|---|---|---|
| Montecchio Maggiore | $2E_y = 81^\circ\ 14'$ | $2E_y = 94^\circ\ 27'$ | $2E_y = 89^\circ\ 54'$ |

Also 2E = 92° 46 and at 150° 2E = 103° 50′ in white light.

Indices:

$\alpha = 1{\cdot}498$ $\beta = 1{\cdot}499$ $\gamma = 1{\cdot}505$ Lévy-Lcx.[4]

Rinne found for crystals from Andreasberg the inclination of the ax. pl. to $\grave{a} = +\ 34^\circ$ (i.e. in obtuse angle of $\grave{a}$ and $\acute{c}$); hence $Bx_o \wedge \acute{c} = +\ 57\frac{1}{2}^\circ$; for others from Viesch, these angles were 6° and $85\frac{1}{2}'$ respectively; for Berufiord + 8° and $83\frac{1}{2}'$; Fassathal 32° and $59\frac{1}{2}$. Lévy-Lcx. give $Bx_o \wedge \acute{c} = +\ 85^\circ\ 30'$. For Turkestan crystals, the ax. pl. is inclined 0° 30′ to *c* (001) Erem., and $2E_r = 52^\circ\ 30'$, $2E_{bl} = 53^\circ\ 20'$. For crystals from the Serra de Botucatú, Brazil, the ax. pl. makes an angle of 19° 35′ with *c* (or $\grave{a}$); sections ∥ *b* show tw. lamellæ ∥ *c*, Hussak, l. c.

For Montecchio Maggiore, Negri found the ax. pl. inclined about + 34° to $\grave{a}$, and hence nearly normal to *t* (201) or $Bx_o \wedge \dot{c} = +57\frac{1}{2}°$; Artini made this angle, for the same locality, − 34°, and the ax. pl. nearly normal to *s* ($\bar{2}01$), but obviously by error (cf. Negri).

Sections ‖ *b* are described by Mld. as having a division into four sectors for all of which $Bx_a \perp b$, but the ax. pl. and the ax. angle are variable. Increase of temperature to 150° changes these, but they return to the original condition upon the reassumption of the water. Heated to 180° the sections become opaque and the change is permanent[5].

This subject has been later studied by W. Klein and particularly by Rinne; the latter describes the presence of five sectors, more or less sharply defined in polarized light, in sections ‖ *b*, bounded externally by the usually occurring planes, that bounded by *s* (201) having an hour-glass form. These sectors show a rather wide variation in the position of the ax. plane.

Increase of temperature (Rinne) causes the axial angle to diminish and at 150° the division into sectors no longer exists; further we have ax. pl. ‖ *b*, and $\mathfrak{a} \perp c$ (001); the structure then is that of an orthorhombic crystal. If the heating is carried on till the crystal loses its transparency, further change goes on, the sectors reappear, the ax. pl. is ⊥ *b* and $\mathfrak{c}$ becomes ⊥ ($\bar{2}01$). If strongly heated, the orientation remains the same but the division into sectors disappears and the double refraction before strong becomes weak, and the bright polarization-colors are changed to a bluish gray. Finally by ignition on a platinum foil the double refraction almost entirely disappears. The changes are obviously connected with the loss of the water, two molecules of which go off at 150° and a third at 180°, all being water of crystallization; this water is reabsorbed in moist air.

**Comp.**—$H_4CaAl_2Si_6O_{18} + 3H_2O$ or $5H_2O.CaO.Al_2O_3.6SiO_2$ = Silica 59·2, alumina 16·8, lime 9·2, water 14·8 = 100.

Strontium is usually present, sometimes up to 3·6 p. c. as shown by Jannasch.

[a] Incl. $Fe_2O_3$. [b] Incl. 0·62 p. c. $Fe_2O_3$.

The red color of the Fassa crystals is due, according to Kenngott, to minute crystalline grains of another mineral, probably iron oxide.

According to Damour, the Färöer mineral loses part of its water in dry air, which it retakes in ordinary air; the loss of the mineral is 2·1 p. c. at 100° C., and 8·7 p. c. between 100° and 150° C.; and this is restored again after 24 hours in the air. At 190° the loss is 12·3 p. c.; and by the end of two months all is regained but 2·1 p. c.

Jannasch found for Berufiord heulandite, Jb. Min., **2**, 269, 1884, also later, ibid., **2**, 39, 1887:

| Temp. | 100°–110° | 150°–160° | 200° | 250° | 300° | 340°–350° | ign.[a] |
|---|---|---|---|---|---|---|---|
| $H_2O$ | 3·33 | 5·97 | 8·05 | 8·89 | 12·66 | 13·45 | 16·82 p. c. |

[a] Over the blast-lamp.

Hersch obtained the following results (see anal. 8) after two hours' heating at each temperature.

| Temp. | 100° | 145° | 195° | 250° | 290° | red ht. |
|---|---|---|---|---|---|---|

**Pyr.**—As with stilbite, p. 584.

**Obs.**—Heulandite occurs principally in basaltic rocks, associated with chabazite, stilbite, and other zeolites; also in gneiss, and occasionally in metalliferous veins.

The finest specimens of this species come from Berufiord, and elsewhere in Iceland; the Färöer; in British India, near Bombay, on the islands of Elephanta and Caranja; also in railroad cuttings in the Bhor and Thul Ghâts, and at other points. It also occurs in the Kilpatrick Hills, near Glasgow; on the I. of Skye; in the Fassathal, Tyrol; Andreasberg, Harz; near Semil and Rodisfort, Bohemia; Poremba, Poland; Marschendorf, Moravia; Neudörfel, near Zwickau, Saxony; Siberia, at Nerchinsk, etc.; in the amygdaloid of Abyssinia; in augite porphyrite of Serra de Botucatú, Brazil. Red varieties occur at Campsie in Stirlingshire, with red stilbite; also in Fassathal, Tyrol; also on the southern slope of the Ak-Burchan Mts., Turkestan; brown in ore beds at Arendal.

In the United States, with stilbite and chabazite on gneiss, at Hadlyme, Ct., and Chester, Mass.; with these minerals and datolite, apophyllite, etc., in amygdaloid at Bergen Hill, New Jersey; sparingly at Kipp's Bay, New York Island, on gneiss, along with stilbite; at McKinney's quarry, Rittenhouse Lane, near Philadelphia, sparingly; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac; in minute crystals, seldom over half a line long, with haydenite, at Jones's Falls, near Baltimore, on a syenitic schist (Lévy's *beaumontite*, which is crystallographically and optically identical with heulandite).

At Peter's Point, Nova Scotia, it occurs in amygdaloid, presenting white and flesh-red colors, and associated with laumontite, apophyllite, thomsonite, etc.; also at Cape Blomidon, in crystals an inch and a half in length; at Martial's Cove, Isle Haute, Partridge Island, Swan's Creek, Two Islands, Hall's Harbor, Long Point.

Named after the English mineralogical collector, H. Heuland, whose cabinet was the basis of the classical work (1837) of Lévy.

**Artif.**—Obtained by Doelter by recrystallization after digesting the powdered mineral for 11 days in water containing carbon dioxide at 170° in a closed tube. The crystals were of characteristic form. An analysis gave Unterweissacher: $SiO_2$ 58·90, $Al_2O_3$ 14·02, CaO 8·53, $Na_2O$ 3·36, $H_2O$ 15·19 = 100. Also by digesting pulverized anorthite with fresh precipitated silica in carbonated water for 14 days at 200°. Jb. Min., **1**, 128, 1890.

Lemberg shows that by digestion in a potassium or sodium chloride solution for a week these alkali metals may be made to replace the calcium, forming a potash- or soda-heulandite (Kalistilbit, Natronstilbit). Zs. G. Ges., **28**, 558, 1876.

**Ref.**—[1] Min., p. 425, 1862; the results of Eremeyev agree closely, Vh. Min. Ges., **13**, 389, 1878. The vertical axis has here (as with Mlr.) half the length assumed by Dx. and some authors, with whom *t* = 101, *s* = 1̄01, *u* = 1̄12, etc. With N.-Z., *s* = 1̄01, *t* = 100, *c* = 001, etc. Cf. also Rinne, Jb. Min., **2**, 25, 1887. Breithaupt made it triclinic, Min., **3**, 449, 1847; cf. Rath, Jb Min., 517, 1874.

[2] Cf. Mlr., Min., p. 438, 1852; Greg, Min., 166, 1858; Dx., l. c., who gives Greg's plane, *z*, the symbol 097, or in the position here taken, 0·18·7.

ORYZITE. Orizite *Grattarola*, Att. Soc. Tosc., **4**, 226, 1879.

In monoclinic crystals, somewhat resembling rice-grains. Habit prismatic, with *m* (110), *g* (011), and rarely *b* (010). Measured angles (approx.): *mm‴* = 40° 30′, *gg′* = 22° 30′, *mg* = 81° 10′. H. = 6. G. = 2·245. Luster vitreous to pearly. Color white. A triclinic form was earlier suggested. Composition, like heulandite. Analyses, Grattarola, l. c.

| | | | | | | |
|---|---|---|---|---|---|---|
| G. = 2·245 | $SiO_2$ 59·54 | $Al_2O_3$ 16·79[a] | CaO 8·67 | Alk. *tr.* | $H_2O$ 14·84 | = 99·84 |
| | 59·20 | 15·71 | 10·31 | *tr.* | 14·38 | = 99·60 |

[a] With some CaO.

Observed in granite blocks from Fonte del Prete, Elba. Named from ορυζα, *rice*. It was made dimorphous with heulandite, but it may be identical with it (cf. Groth, Zs. Kr., **4**, 641, 1880).

439. **BREWSTERITE.** *Brooke*, Ed. Phil. J., **6**, 112, 1822. Diagonit *Breith.*, Char., 118, 1832.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}40486 : 1 : 0{\cdot}42042$; $\beta = {}^*86^\circ\ 20' = 001 \wedge 100$ Brooke[1].

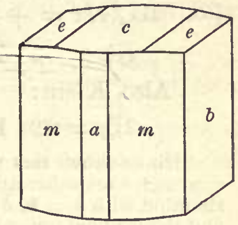
$100 \wedge 110 = 22^\circ\ 0'$, $001 \wedge 101 = 44^\circ\ 29\frac{2}{3}'$, $001 \wedge 011 = 22^\circ\ 45\frac{1}{2}'$.

**Forms**: *a* (100, *i*-ī), *b* (010, *i*-ì), *c* (001, *O*); *m* (110, *I*), *t* (120, *i*-2̀); *e* (016, $\frac{1}{6}$-ì).

Angles: *mm‴* = *44° 0′, *tt′* = 102° 7′, *ee′* = *8° 0′, *cm* = 86° 36′.

Crystals prismatic, flattened ‖ *b*; faces *m*, *t* vertically striated.
Cleavage: *b* perfect; *a* in traces. Fracture uneven. Brittle. H. = 5.

G. = 2·45 Dmr. Luster vitreous; on *b* pearly. Color white, inclining to yellow and gray. Transparent to translucent.



Optically +. Ax. pl. and $Bx_a \perp b$. Extinction-angle or $Bx_{o.r} \wedge \dot{c} = +22°$. Dispersion $\rho > v$ weak; crossed distinct, the ax. planes inclined 1° to 2° for red and blue. Axial angles:

$2E_r = 94°$, $2E_{bl} = 93°$. Again 2E = 102°–103° for white light, Dx.[2]

The axial angle increases somewhat on heating, from $2E_r = 93°\ 43'$ at 8°·8 to 95° 26′ at 105°·5. Further the axial plane for red is turned through an angle of 4° 54′ between 21°·5 and 146°·5.

Sections ‖ *b* show a division into three sectors: a central wedge-shaped portion whose sides make angles of 17° and 13°, respectively, with the front and back prismatic edges; this has also an extinction-angle of + 22°. Further, two triangular lateral sectors in which this angle is 40°, Dx.[2]

**Comp.**—$H_4(Sr,Ba,Ca)Al_2Si_6O_{18} + 3H_2O$ or $(Sr,Ba,Ca)O.Al_2O_3.6SiO_2.5H_2O$. If Sr : Ba : Ca = 4 : 2 : 1, this requires: Silica 54·3, alumina 15·4, strontia 8·9, baryta 6·6, lime 1·2, water 13·6 = 100.

**Anal.**—1, Connel, Ed. N. Phil. J., **10**, 35, 1830. 2, Thomson, Min., **1**, 348, 1836. 3, J. W. Mallet, Phil. Mag., **18**, 218, 1859.

| | $SiO_2$ | $Al_2O_3$ | BaO | SrO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. Strontian | 53·67 | 17·49 | 6·75 | 8·32 | 1·35 | 12·58 | $Fe_2O_3$ 0·29 = 100·45 |
| 2. " | 53·04 | 16·54 | 6·05 | 9·01 | 0·80 | 14·74 | = 100·28 |
| 3. " | $\frac{4}{4}$ 54·42 | 15·25 | 6·80 | 8·99 | 1·19 | 13 22 | = 99·87 |

According to Damour, loses water in unheated dried air, experiencing a loss of weight of 1·65 p. c. in the course of a month. At 100° C., after 2 hours, the loss is 0·2 p. c., but at 130° C. 7·7 p. c., when the mineral while still hot is electric, the crystals mutually attracting; they have become opaque and pearly; by 48 hours' exposure to ordinary air, the loss is reduced to 2·7 p. c. At 190° C., the loss is 8·2 p. c.; this is reduced to zero after 48 hours' exposure; and at 270°, the loss is 10·1 p. c., which is reduced to 1·2 p. c. after 8 days' exposure. At a dull red heat the loss is 12·8 p. c., and at a bright red, 13·3 p. c.

**Pyr., etc.**—B.B. swells up and fuses at 3 to a white enamel. Decomposed by acids without gelatinizing.

**Obs.**—First observed at Strontian in Argyleshire, with calcite. Occurs also at the Giant's Causeway, coating the cavities of amygdaloid; in the lead mines of St. Turpet; near Freiburg in Breisgau; at the Col du Bonhomme, S.W. of Mont Blanc, on a quartz rock; near Barèges, in the Pyrenees, in a calcareous schist; and it has been reported from the department of the Isère in France.

Named after Sir David Brewster (1781–1868).

**Ref.**—[1] Ed. Phil. J., **6**, 112, 1822. Cf. Haid, Min. Mohs, **3**, 80, 1825; Pogg., **5**, 161, 1825. The angle β = 86° 56′ of most recent authors is based upon what is apparently a misprint in Dx., Min., **1**, p. 421, 1862. [2] Dx., l. c., also N. R., 124, 1867.

**440. EPISTILBITE.** Epistilbit *G. Rose*, Pogg., **6**, 183, 1826. Monophan *Breith.*, Char., 279, 1823. Parastilbite *S. von Waltershausen*, Vulk. Gest., 251, 1853. Reissite *K. v. Fritzsch*, Hbg., Min. Not., **9**, 22, 1870.

Monoclinic. Axes $\grave{a} : \overset{1}{\bar{b}} : \dot{c} = 0·50430 : 1 : 0·58006$; $\beta = 54°\ 53' = 001 \wedge 100$ Rose-Tenne[1].

$100 \wedge 110 = 22°\ 25'$, $001 \wedge 101 = 29°\ 31\frac{1}{6}'$, $001 \wedge 011 = 25°\ 23'$.

**Forms**[2]: *a* (100, *i*-ī) as tw. pl., *b* (010, *i*-ì), *c* (001, *O*); *m* (110, *I*); *e* (1̄01, 1-ī); *u* (011, 1-ì); *s* (1̄12, ½), *p* (1̄11, 1).

| | | | |
|---|---|---|---|
| *mm‴* = *44° 50′ | *cs* = 38° 13′ | *pp′* = 50° 46′? | *mu* = 49° 55′ |
| *uu′* = *50° 46′ | *cp* = 72° 12′ | *ss′* = 32° 21′ | *c*c̲ = *70° 14′ |
| *ce* = 70° 13′ | *cm′* = 122° 7½′ | *bs* = 73° 49½′ | |

Crystals uniformly twins; habit prismatic: (1) tw. pl. *a*, common; also (2) tw. pl. *m*. The crystals sometimes cruciform penetration-twins. Faces *s* rounded, *b* brilliant. In radiated spherical aggregations; also granular.

Cleavage: *b* very perfect. Fracture uneven. Brittle. H. = 4–4·5, on *b* 3·5. G. = 2·25. Colorless to white, yellowish. Luster vitreous. Optically −. Ax. pl. ∥ b. $Bx_a \wedge \acute{c} = +8\frac{1}{2}$ to $9\frac{1}{2}$. Axial angles, Tenne:

$2E_r = 73° 30'$ Li $2E_y = 75° 35'$ Na $2E_{gr} = 76° 40'$ Tl

Also, Klein:

$2E_r = 69° 12'$ $2E_y = 70° 45'$ $2E_{gr} = 71° 55'$

Rinne shows that with increase of temperature the axes $\mathfrak{c}$ (= $Bx_a$) in the twinned crystals approach each other and finally unite, when the twinning disappears and the crystals are orthorhombic with $\breve{a} = \mathfrak{b}$, $\bar{b} = \mathfrak{a}$, $\acute{c} = \mathfrak{c}$. Exposed to the air the water expelled is slowly reabsorbed and the original optical and crystallographic characters reassumed; the orthorhombic characters, however, are retained if the crystals are embedded in Canada balsam. Ber. Ak. Berlin, 1181, 1890.

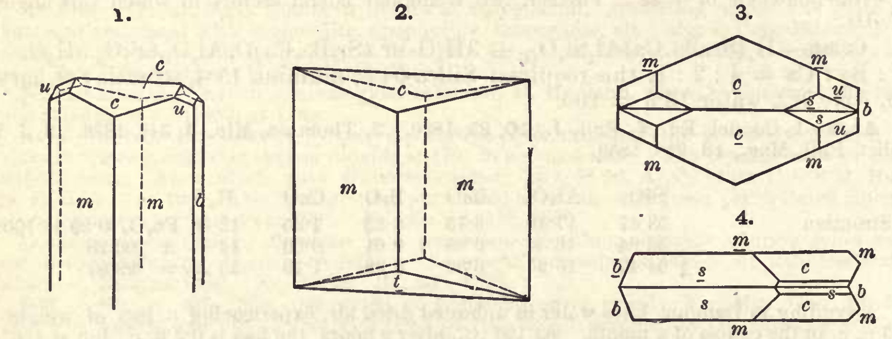

Fig. 1, *Reissite*, Luedecke. 2, Iceland, Hintze. 3, 4, Trechmann.

**Comp.**—Probably like heulandite, $H_4CaAl_2Si_6O_{18} + 3H_2O$ or $CaO.Al_2O_3.6SiO_2.5H_2O$ = Silica 59·2, alumina 16·8, lime 9·2, water 14·8 = 100. A little sodium replaces part of the calcium.

**Anal.**—1, G. Rose, l. c. 2, Hersch, Inaug. Diss., p. 20, Zürich, 1887. 3, 4, Jannasch, Henniges, Jb. Min., **2**, 262, 274, 1882. Also ib., **1**, 50, 1880.

The formula is also written (Groth) $H_6Ca_2Al_4(SiO_3)_{11} + 7H_2O$ which requires: Silica 57·1, alumina 17·6, lime 9·7, water 15·6 = 100.

| | G. | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. Berufiord | 2·250 | 58·59 | 17·52 | 7·56 | 1·78 | 14·48 | = 99·93 |
| 2. Djupivogur | 2·207 | 58·18 | 16·35 | 7·21 | 2·07 | 16·34 | = 100·15 |
| 3. Berufiord | 2·250 | $\frac{2}{2}$ 57·63 | 17·43 | 8·08 | 1·57 | 15·32 | $K_2O,Li_2O$ 0·05 = 100·08 |
| 4. Loc. unknown | 2·247 | $\frac{2}{2}$ 56·65 | 18·68 | 8·68 | 1·47 | 15·60 | = 101·08 |

A zeolite, probably epistilbite, from Lunddörrsfjäll gave Igelström: $SiO_2$ 58·35, $Al_2O_3$ 16·67, CaO 10·63, $H_2O$ 13·76 = 99·41. Jb. Min., 361, 1871.

Jannasch obtained further (anal. 4):

| Temp. | 100°–105° | 150°–160° | 200° | 260°–280° | 300°–350° | Rd. ht. |
|---|---|---|---|---|---|---|
| $H_2O$ | 1·76 | 3·58 | 4·48 | 10·22 | 12·13 | 15·52 |

Cf. also Jannasch, Jb. Min., **2**, 206, 1884; Bodewig, Zs. Kr., **8**, 611, 1884, **10**, 276, 1885.

**Pyr., etc.**—B.B. intumesces and forms a vesicular enamel. Soluble with difficulty or imperfectly in concentrated hydrochloric acid without gelatinizing.

**Obs.**—Occurs with scolecite at the Berufiord in Iceland; the Färöer; at Poona in India; in small flesh-colored crystals at Skye; in small reddish crystals, nearly or quite opaque, with stilbite, at Margaretville, N Scotia, 7 m. E. of Port George. Reported as occurring with stilbite, apophyllite, etc., at Bergen Hill, N. J. With heulandite, stilbite, etc., at Viesch in the Valais, Switzerland.

*Parastilbite* (cf. Tenne, l. c.) is from the Borgarfiord, Iceland. *Reissite* (cf. Luedecke, l. c.) is from Santorin.

**Ref.**—[1] Pogg., **6**, 183, 1826, Jb. Min., **1**, 43, 1880; the angles are quite uncertain as shown later by Trechmann, ib., **2**, 260, 1882, who gives a comparative table for epistilbite, reissite, parastilbite. The monoclinic character was also recognized by Dx , Bull Soc. Min., 2, 161, 1879; it had earlier been regarded as orthorhombic.

[2] Cf. authors noted above. Also on reissite, Hbg., Min Not., **9**, 22, 1870; Luedecke, Jb. Min., **1**, 162, 1881. On parastilbite, Tenne, Jb. Min., **2**, 195, 1881. Also Hintze, Zs. Kr., **8**, 605, 1884.

## Phillipsite Group. Monoclinic.

**441. Phillipsite.** **442. Harmotome.** **443. Stilbite.**

These three species have not only nearly the same axial ratios (p. 571), but they are also closely related in habit and method of twinning, as explained under the description of each. The relation is particularly close between phillipsite and harmotome.

Fresenius has shown that the species of this group may be regarded as forming a series, in which the ratio of $\overset{II}{R} : \overset{III}{R}_2$ is constant (= 1 : 1), while the silica and water both vary between certain limits. The end compounds assumed are:

$$RAl_2Si_6O_{16} + 6H_2O$$
$$R_2Al_4Si_4O_{16} + 6H_2O$$

Here R = Ca chiefly, in phillipsite and stilbite, and Ba in harmotome; also in smaller amounts $Na_2, K_2$. The first of the above compounds may be regarded as a hydrated calcium albite, the second as a hydrated anorthite. The subject, however, requires further study; the formulas given on p. 571 and beyond are those corresponding to reliable analyses of certain typical occurrences.

---

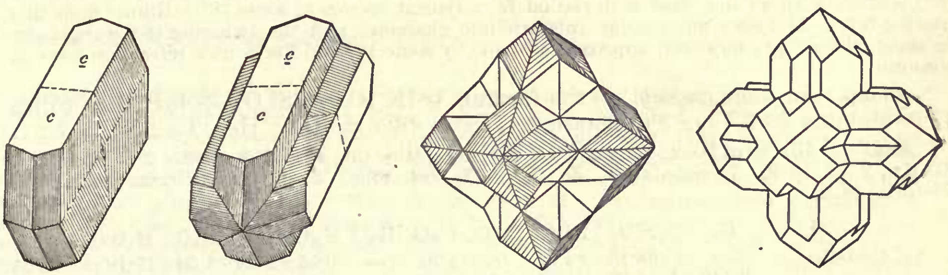
**441. PHILLIPSITE.** *Lévy*, Ann. Phil., **10**, 362, 1825. Lime-Harmotome. Kalk-Harmotom *Germ.* Kalk-Harmotom, Normalin, *Breith.*, Schw. J., **50**, 327, 1827, Uib., 32, 1830, Char., 126, 1832. Christianite *Dx.*, Ann. Mines, **12**, 373, 1847.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 0{\cdot}70949 : 1 : 1{\cdot}2563$; $\beta = {}^*55^\circ\ 37' = 001 \wedge 100$ Streng[1].

$100 \wedge 110 = 30^\circ\ 21'$, $001 \wedge \bar{1}01 = {}^*90^\circ\ 0'$, $001 \wedge 011 = 46^\circ\ 2'$.

**Forms:** *a* (100, *i*-ī), *b* (010, *i*-ì), *c* (001, *O*); *m* (110, *I*), *n* (120, *i*-2̀); *d* (501, − 5-ī), *f* (1̄01, 1-ī); *e* (011, 1-ì).

Angles: $mm''' = {}^*60^\circ\ 42'$, $nn' = 80^\circ\ 59\tfrac{1}{2}'$, $af = 34^\circ\ 23'$, $cd = 50^\circ\ 36\tfrac{1}{2}'$, $cm = 60^\circ\ 50'$, $ee' = 92^\circ\ 4'$.



1. 2. 3. 4.

Figs. 1, 2, Sirgwitz, Trippke. 3, 4, After Köhler.

Crystals uniformly penetration-twins, but often simulating orthorhombic or tetragonal forms. Twins sometimes, but rarely, simple (1) with tw. pl. *c*, and then cruciform so that diagonal parts on *b* (f. 1) belong together, hence a fourfold striation, ‖ edge *b*/*m*, may be often observed on *b*. (2) Double twins, the simple twins just noted united with *e* (011) as tw. pl., and, since *ee'* varies but little from 90°, the result is a nearly square prism, terminated by what appear to be pyramidal faces each with a double series of striations away from the medial line (cf. f. 2). These twins may have the prism formed either by *b* with its characteristic striations, with or without the reëntrant angle; or the external faces may belong to *c* (f. 2) when *b* appears in the reëntrant angle only (if this is shown); or still again the reëntrant angle may be absent and the crystals interpenetrate each other irregularly, so that an external face is formed in part by *b*, in part by *c*. Rarely[2] this double twin, showing a square prism formed by the faces *b*, *b*, may be terminated by the unusual form *a* (100) with four reëntrant angles of about 47¾°. Finally (3), three double twins of the ordinary type may be united to a single complex form with *m* as tw. pl. (f. 3, 4). This last may yield forms appearing like a rhombic dodecahedron, with or without a depression at the extremity of the octahedral axes; each rhombic face may then be divided into four fields by striations diverging from the center and parallel to the position that would be occupied by a plane on the octahedral solid angle of the dodecahedron (cf. f. 3).

Faces *b* often finely striated as just noted, but striations sometimes absent and in general not so distinct as with harmotome; also *m* striated ‖ edge *b*/*m*; further, *a*, *c*, and *d* (501) more or less distinctly ‖ edge *a*/*c*. Crystals either isolated, or grouped in tufts or spheres that are radiated within and bristled with angles at surface.

Cleavage: *c*, *b*, rather distinct. Fracture uneven. Brittle. H. = 4–4·5. G. = 2·2. Luster vitreous. Color white, sometimes reddish. Streak uncolored. Translucent to opaque.

Optically +. Ax. pl. and $Bx_o \perp b$. The ax. pl. lies in the obtuse angle of ȧ ċ, and is usually inclined to *c* (that is, to ȧ) about 15° to 20°, or 75° to 70° to the normal to *c*. The position, however, is variable, as also the axial angles. Dx. obtained:

| | Richmond | Dyref. | Oberwinter | C. d. Bove | Somma | Marburg | Annerd. |
|---|---|---|---|---|---|---|---|
| 𝔠 *c* = | + 60° 11′ | 71° 36′ | 72° | 73° 15′ | 73° 21′ | 74° 51½′ | 75° 0′ |
| $Bx_a \wedge \dot{c}$ = | − 85° 26′ | − 74° 1′ | − 73° 37′ | − 72° 26′ | − 72° 17′ | − 70° 45½′ | − 70° 37′ |

| | | | | |
|---|---|---|---|---|
| Richmond | $2H_{a.r} = 84° 8\frac{1}{2}'$ | $2H_{o.r} = 103° 21'$ | $2H_{a.y} = 84° 54\frac{1}{2}'$ | $2H_{o.y} = 103° 5'$ |
| Mte. Somma | $2H_{a.r} = 69° 55'$ | $2H_{o.r} = 112° 33'$ | | |
| Marburg | $2H_{a.r} = 70° 50'$ | $2H_{o.r} = 129° 15'$ | Dyrefiord | $2H_{o.r} = 98° 13'$ |

Fresenius found for Nidda crystals the axial angle inclined about 10° to *c* (hence 𝔞 *c* = 80° and $Bx_a \wedge \dot{c} = -65° 37'$); for yellow this angle is about 1° greater than for red.

According to Langemann[3] the individuals which form the complex twins of phillipsite are strictly triclinic since, for example, sections ‖ *f* (1̄01) show a deviation of the planes of vibration from the *b* axis, amounting in the Nidda phillipsite to 12½°; further, sections ‖ *c* show a division into sectors with in one case a deviation for adjacent sectors of some 18°. Rinne[3] finds that heating (cf. p. 571) does not change this triclinic character and the twinning structure is also retained; the ax. pl., however, approaches *c* (001) by some 10° and the double refraction loses in strength.

**Comp.**—In some cases (Rg.) the formula is $(K_2,Ca)Al_2Si_4O_{12} + 4\frac{1}{2}H_2O$ = Silica 48·8, alumina 20·7, lime 7·6, potash 6·4, water 16·5 = 100. Here Ca : $K_2$ = 2 : 1.

According to Damour, the Kaiserstuhl crystals (mixed with a little faujasite) lose 8 p. c. after a month in dried air, and regain all again in ordinary air in 24 hours. Heated to 50° C. for an hour, the mineral loses 12·3 p. c., and recovers nearly all in 24 hours' exposure to ordinary air, but becomes a powder and opaque (the faujasite remaining transparent). Heated to 150° C., the loss is 16 p. c., and only 0·8 p. c. after exposure again to the air for 4 days. At 250° C., the loss is 18·5 p. c., part of which is due to the faujasite; it is reduced to 9 p. c. in the free air.

Fresenius found that phillipsite began to be opaque at 150° and to fall to pieces; the amount of water gradually diminishes with rise in temperature and increases as it falls, each temperature corresponding to a definite amount.

**Pyr., etc.**—B.B. crumbles and fuses at 3 to a white enamel. Gelatinizes with hydrochloric acid.

**Obs.**—In translucent crystals in basalt, at the Giant's Causeway, Ireland; in small colorless crystals, and in spheroidal groups, in leucitophyre, at Capo di Bove, near Rome; in crystals and radiating masses at Aci Castello and elsewhere in Sicily; among the lavas of Mte. Somma; at Stempel, near Marburg; Habichtswald, near Cassel; Annerod, near Giessen; near Eisenach, in Saxe Weimar; Petersberg, in the Siebengebirge; Nidda in Hesse; Laubach; in the basalt of the Limbacher Kopf near Asbach; in the Kaiserstuhl, with faujasite; at Härtlingen, Nassau; Salesl, Bohemia, on the right bank of the Elbe; in the ancient lavas of the Puy-de-Dôme at Cap de Prudelles near Royat, and other points; also at Verrières, Loire; on the west coast of Iceland, the shores of Dyrefiord. Very small transparent crystals, of recent formation, in the masonry at the hot baths of Plombières, France, observed by Daubrée; also at Bourbonne-les-Bains and elsewhere.

Found in minute crystalline aggregates and irregular spherical groups bristling with crystals in the deep-sea dredging by the "Challenger" from the bottom of the central Pacific Ocean, south of the Sandwich Islands. They are embedded in a red clay with ferro-manganesian nodules (cf. p. 259), chondrules of enstatite, etc.; they are believed to have been formed at the ocean bottom by the decomposition of an augitic lava. An analysis by Renard gave:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | CaO | MgO | $K_2O$ | $Na_2O$ | $H_2O$(125°) | ign. |
|---|---|---|---|---|---|---|---|---|---|
| 48·70 | 17·58 | 6·17 | *tr.* | 1·70 | 1·02 | 4·83 | 3·75 | 7·95 | 9·47 = 101·17 |

The iron is due to impurity. See Rep. Challenger Ex., vol. **1**, 774, 815, 816, 1885; John Murray in Encycl. Brit., **18**, 125, 1885; for the description of the forms, etc., Renard, Bull. Ac. Belg., **19**, 88, 182, 1890; a general account is given in Proc. R. Soc. Edinb., **12**, 474, 1884.

Named after the English mineralogist, W. Phillips (d. 1828). The name *christianite* was given by Des Cloizeaux (after Christian VIII. of Denmark) to the Marburg harmotome and crystals from Iceland; and in his Min., 1862, he places all of phillipsite under his name christianite.

**Ref.**—[1] Jb. Min., 585, 1875. The monoclinic character of the species was first assumed by Groth and definitely proved by Streng. Cf. Köhler, Pogg., **37**, 560, 1836; Streng, Jb. Min., 561, 1874; Groth, Tab. Ueb., pp. 62, 104, 1874; also Trippke, Jb. Min., 681, 1878; Fresenius, Zs. Kr., **3**, 42, 1879; Zeph., Zs. Kr., **5**, 96, 1880; Stadtländer, Jb. Morvenite *Thom.*, Min., **1**, 351, 1836. Baryt-Harmotome. Barytkreuzstein *Germ.*

Monoclinic. Axes $\grave{a} : \overset{1}{\bar{b}} : \grave{c} = 0{\cdot}70315 : 1 : 1{\cdot}2310$; $\beta = {}^{*}55^\circ\ 10' = 001 \wedge 100$ Des Cloizeaux[1].

$100 \wedge 110 = 29^\circ\ 59\tfrac{1}{2}'$, $001 \wedge 101 = 35^\circ\ 41\tfrac{5}{6}'$, $001 \wedge 011 = 45^\circ\ 17\tfrac{5}{6}'$.

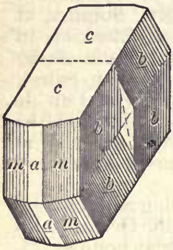
**Forms**[1]:

*a* (100, *i*-ī)
*b* (010, *i*-ì)
*c* (001, *O*)
*v* (410, *i*-$\bar{4}$)
*w* (520, *i*-$\tfrac{5}{2}$)
*m* (110, *I*)
*t* (101, − 1-ī)
*ε* (702, − $\tfrac{7}{2}$-ī)
*f* ($\bar{1}$01, 1-ī)
*e* (011, 1-ì) as tw. pl.

*mm'''* = *59° 59'
*vv'''* = 16° 25'
*ww'''* = 26° 0'
*at* = 19° 28'
*cε* = 48° 11'
*cf* = *90° 0'
*cm* = 60° 21'
*ee'* = 90° 36'

Crystals uniformly cruciform penetration-twins with *c* as tw. pl.; either (1) simple twins (f. 1) or (2) united as fourlings with tw. pl. *e*. These double twins often have the aspect of a square prism with diagonal pyramid, the latter with characteristic feather-like striations from the medial line. Also (3) in more complex groups of three double twins, with *m* as tw. pl. (cf. f. 4, p. 579); see further under phillipsite, where the forms are more fully described.

1.



Morvenite, Dx.

Cleavage: *b* easy, *c* less so. Fracture uneven to subconchoidal. Brittle. H. = 4·5. G. = 2·44–2·50. Luster vitreous. Color white; passing into gray, yellow, red, or brown. Streak white. Subtransparent to translucent. Optically +. Ax. pl. and $Bx_a \perp b$. Ax. pl. in obtuse angle $\grave{a}\ \dot{c}$ and inclined about 65° to $\grave{a}$ and 60° to $\dot{c}$; more exactly (Dx.), $Bx_{o.r} \wedge \dot{c} = +60° 32'$, $Bx_{o.bl} \wedge \dot{c} = +59° 55'$. Axial angle $2H_{a.r} = 87° 2'$, Dx. Indices:

$$\alpha = 1·503 \qquad \gamma = 1·508 \text{ Lévy-Lcx.} \qquad \beta = 1·516 \text{ Dx.}^2$$

According to Langemann[2], harmotome in a manner similar to phillipsite deviates optically from the requirements of the monoclinic system, as shown in sections ⊥ *b* and *c*. Rinne[2] shows that by heating (see p. 571) these optical characters, which refer the simple crystals of harmotome strictly to the triclinic system, are not changed, but the ax. pl. has approached *c* (001) by some 50°, while the double refraction has increased in strength.

**Comp.**—In part $H_2(K_2,Ba)Al_2Si_5O_{15} + 4H_2O$ or $(K_2,Ba)O.Al_2O_3.5SiO_2.5H_2O$ = Silica 47·1, alumina 16·0, baryta 20·6, potash 2·1, water 14·1 = 100.

**Anal.**—1, 3, Rg., Pogg., **110**, 624, 1860. 2, Hersch, Inaug. Diss., 18, Zürich, 1887. 4, Reynolds, Q. J. G. Soc., **27**, 374, 1871. 5, Fresenius, Zs. Kr., **3**, 42, 1878. 6, Dmr., Ann. Mines, **9**, 345, 1846.

| | G. | $SiO_2$ | $Al_2O_3$ | BaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. Andreasberg | | 48·49 | 16·35 | 20·08 | *tr.* | 2·07 | 13·00 = 99·99 |
| 2. " | | 45·72 | 16·79 | 22·34 | — | — | 15·18 = 100·03 |
| 3. Strontian | 2·354 | 47·52 | 16·94 | 20·25 | 1·09 | 1·00 | 13·45 = 100·25 |
| 4. " | | 48·02 | 17·42 | 20·17 | 0·62 | | 13·77 = 100 |
| 5. Oberstein | 2·402 | 47·42 | 15·89[a] | 18·98 | 1·71 | 0·48 | 15·14 MgO 0·13 = 99·75 |
| 6. Strontian, *Morvenite* | 2·498 | 47·60 | 17·04[b] | 20·86 | 0·74 | 0·81 | 14·16 = 101·21 |

[a] Incl. 0·09 $Fe_2O_3$. [b] Incl. 0·65 $Fe_2O_3$.

According to Damour, the Scotch harmotome loses 4·3 p. c. by 6 months' exposure to dried air. Heated to 100° C. it loses 1·8 p. c.; between 100° and 150°, 9 9 p. c.; between 100° and 190°, 13·5 p. c.; and after 24 h. exposure to the ordinary air, what is lost is restored. At a dull red heat the loss is 14·65 p. c., and the mineral is disaggregated; the total loss at a bright red heat is 14·70 p. c.

Hersch (ref. p. 571) obtained for the loss of water, after two hours' heating in each case:

| Temp. | 100° | 150° | 203° | 252° | 295° | red ht. |
|---|---|---|---|---|---|---|
| $H_2O$ | 2·74 | 5·74 | 9·23 | 10·67 | 12·42 | 15·29 p. c. |

**Pyr., etc.**—B.B. whitens, then crumbles and fuses without intumescence at 3·5 to a white translucent glass. Some varieties phosphoresce when heated. Decomposed by hydrochloric acid without gelatinizing.

**Obs.**—Harmotome occurs in basalt and similar eruptive rocks, also phonolyte, trachyte; not infrequently on gneiss, and in some metalliferous veins.

Occurs at Strontian, in Scotland, in fine crystals, some an inch through; in a metalliferous vein at Andreasberg in the Harz; at Rudelstadt in Silesia; at Oberstein, implanted on agate in siliceous geodes; at Kongsberg in Norway; in quartz syenite of Tonsenås near Christiania; with analcite in the amygdaloid of Dumbartonshire.

In the U. S., in small brown crystals with stilbite on the gneiss of New York island (4th Av. tunnel excavations). From a mine near Rabbit Mt., 22 miles W.S.W. of Port Arthur or the north shore of L. Superior, Ontario. The crystals are chiefly implanted upon calcite, which is associated with amethyst, fluorite, etc.

Named from ἀρμός, *joint*, and τέμνειν, *to cut*, alluding to the fact that the pyramid (made by the prismatic planes in twinning position) divides parallel to the plane that passes through the terminal edges.

The name *Andreolite* of Delamétherie (derived from the locality at Andreasberg) has the priority , and also *Ercinite* of Napione; but Haüy substituted *harmotome*, of no better signification, and all subsequent mineralogists have followed him.

**Ref.**—[1] Ann. Mines, **9**, 339, 1846; he unites morvenite and harmotome; also Min., **1**, 412, 1862, Ann. Ch. Phys., **13**, 417, 1868; Rg., Zs. G. Ges., **20**, 589, 1868; Kloos, Jb. Min., **2**, 212, 1885. Also earlier, Köhler, Pogg., **37**, 561, 1836.

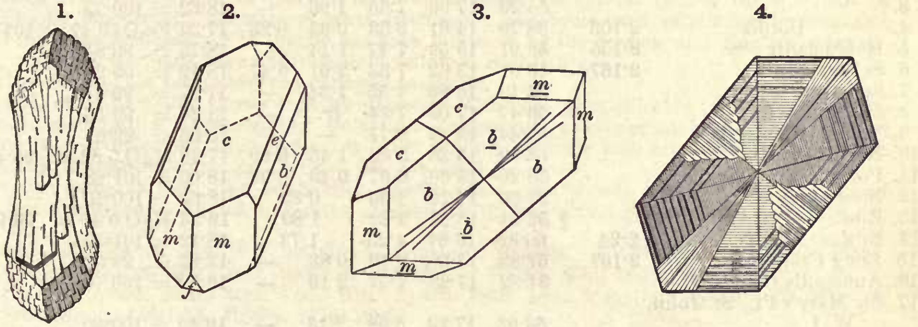
Puflerit *Bukeisen*, Ber. Ak. Wien, **24**, 286, 1857; Hypostilbite *Dana*, Min., p. 441, 1868.

Monoclinic. Axes: $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}76227 : 1 : 1{\cdot}19401$; $\beta = 50° \, 49\frac{3}{4}' = 001 \wedge 100$ Lasaulx[1].

$100 \wedge 110 = 30° \, 34\frac{5}{6}'$, $001 \wedge \bar{1}01 = 89° \, 30'$, $001 \wedge 011 = 42° \, 47\frac{1}{3}'$.

**Forms**[1]: *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$), *c* (001, *O*); *m* (110, *I*); *τ* (250, *i*-$\frac{5}{2}$)[3]? *t* (130, *i*-$\dot{3}$)[2]?; *f* ($\bar{1}$01, 1-$\bar{i}$); *e* (011, 1-$\breve{i}$).

Angles: *a'f* = 39° 40', *mm'''* = *61° 9¾', *ττ'* = 68° 11', *tt'* = 58° 51', *cm* = *57° 3½', *ee* = 85° 35'.



1, Sheaf-like crystal. 2–4, Lasaulx: 2, ideal simple crystal; 4, section ‖ *b* in polarized light.

Crystals uniformly cruciform penetration-twins with tw. pl. *c*, analogous to phillipsite and harmotome. The apparent form a rhombic pyramid (f. 2) whose faces are in fact formed by the planes *m* and *m*; the vertical faces being then the pinacoids *b* and *c*. Usually thin tabular ‖ *b*. These compound crystals are often grouped in nearly parallel position, forming sheaf-like aggregates (f. 1) with the side plane (*b*), showing its characteristic pearly luster, often deeply depressed. Also divergent or radiated; sometimes globular and thin lamellar-columnar.

Cleavage: *b* perfect. Fracture uneven. Brittle. H. = 3·5–4. G. = 2·094–2·205; 2·161 Haid. Luster vitreous; of *b* pearly. Color white; occasionally yellow, brown, or red, to brick-red. Streak uncolored. Transparent to translucent.

Optically —. Ax. pl. ‖ *b*. $Bx_a$ inclined 5° to axis *à* in obtuse angle *à ć*; hence $Bx_a \wedge \grave{c} = -55° \, 50'$. Ax. angle approx. 52° to 53° (blue glass) Lsx. Indices:

Kilpatrick $\alpha = 1{\cdot}494$ $\beta = 1{\cdot}498$ $\gamma = 1{\cdot}500$ Lévy-Lcx.[4]

Langemann[4] shows that strictly considered stilbite must be regarded as composed of triclinic individuals. Sections ‖ $\bar{1}$01 show sectors with the extinction inclined 5° to the edge formed with the plane *b*; sections ‖ *b* (f. 4. Lsx.) show four sectors, whose extinction-directions are inclined to one another 10°, separated by radiating portions of variable extinction; sections ‖ *c* show a central portion with parallel extinction and strips at the side in which it is inclined 2½° to the *b* edge.

Rinne[4] found that in sections ‖ *b*, which showed four sectors with the extinction inclined 10° to each other (the axis 𝔞 coinciding with the direction of elongation), after being strongly heated and made transparent in oil (p. 571), the axes 𝔠 and 𝔟 became respectively ‖ and ⊥ to edge *c* (001). The effect of increase of temperature had been to give it the molecular structure of an orthorhombic crystal, the ax. pl. becoming ‖ *c* and $Bx_a$ (= 𝔠) coinciding with the axis *à*.

**Comp.**—For most varieties $H_4(Na_2,Ca)Al_2Si_6O_{18} + 4H_2O$ or $(Na_2,Ca)O.Al_2O_3.6SiO_2.6H_2O$ = Silica 57·4, alumina 16·3, lime 7·7, soda 1·4, water 17·2 = 100. Here $Ca : Na_2 = 6 : 1$.

Some kinds show a lower percentage of silica, and these have been called *hypostilbite*, Dana, Min., p. 441, 1868; cf. anals. 22–25.

According to Damour, loses 1·3 p. c. at 100° C.; 13 p. c. between 100° and 150° C.; regaining all lost but 3·1 p. c. after 5 days' exposure to the ordinary air; at 170° C. the loss is 16·2 p. c., which is reduced to 9·2 p. c. after 15 days' exposure.

Hersch (l. c.) obtained for the loss of water, after two hours' heating in each case:

| Temp. | 104° | 150° | 210° | 250° | 290° | red ht. |
|---|---|---|---|---|---|---|
| $H_2O$ | 3·84 | 8·71 | 12·16 | 13·60 | 14·78 | 18·63 p. c. |

**Pyr., etc.**—B.B. exfoliates, swells up, curves into fan-like or vermicular forms, and fuses to a white enamel. F. = 2–2·5. Decomposed by hydrochloric acid, without gelatinizing. The *sphærostilbite* gelatinizes, but Heddle says this is owing to a mixture of *mesolite* with the stilbite.

**Obs.**—Stilbite occurs mostly in cavities in amygdaloidal, basalt, and similar rocks. It is also found in some metalliferous veins, and in granite and gneiss.

Abundant on the Färöer Islands, in Iceland, and on the Isle of Skye, in amygdaloid; also found on the Isle of Arran, Scotland; in Dumbartonshire, at Long Craig and at Kilpatrick, Scotland, in red crystals; at Kincardine, Kilmalcolm, Campsie, Scotland; at the Giant's Causeway and in the Mourne Mts., etc., Ireland; at Andreasberg in the Harz, and Kongsberg and Arendal in Norway, with iron ore; on the Seisser Alp in Tyrol and at the Pufler-loch (*puflerite*); on the granite of Striegau, Silesia; a brown variety on granite, at the copper mines of Gustafsberg, near Falun in Sweden. A common mineral in the Deccan trap area of British India, often in large beautiful sheaf-like forms of a salmon-pink color associated with apophyllite; fine crystals come from the Bhor and Thul Ghâts, also Poona, the island Elephanta, Bombay harbor, etc. (Mallet, Min. India, p. 123, 1887). In augite-porphyrite in the Serra de Brotas, northeast of Botucatú, Brazil.

In North America, sparingly in small crystals at Chester and the Somerville syenite quarries, Mass.; at the gneiss quarry, Thachersville, Conn., in crystals lining cavities in coarse granite; at Hadlyme, in radiated forms on gneiss, associated with epidote, garnet and apatite; at Phillipstown, N. Y., in crystals or fan-like groups; opposite West Point, in a vein of decomposing bluish feldspar, intersecting gneiss, in honey-yellow crystals; in the greenstone of Piermont, in minute crystals; in scopiform crystals of a dull yellow color, near Peekskill, N. Y.; and at Bergen Hill, New Jersey, in small but bright crystals; also at the Michipicoten Islands, Lake Superior.

At Partridge Island, Nova Scotia, forming a perpendicular vein from 3 to 4 inches thick, and from 30 to 50 feet long, intersecting amygdaloid, its colors white and flesh-red; also at Isle Haute, Digby Neck, Gulliver's Hole, Black Rock, Cape Blomidon, Hall's Harbor, Long Point.

The name *stilbite* is from *στίλβη, luster;* and *desmine* from *δέσμη, a bundle.* The species stilbite, as adopted by Haüy, included Strahlzeolith *Wern.* (radiated zeolite, or the above), and Blätterzeolith *Wern.* (foliated zeolite, or the species heulandite, p. 574). The former was the typical part of the species, and is the first mentioned in the description; and the latter (made the variety *stilbite anamorphique*) he added to the species, as he observes, with much hesitation. In 1817 Breithaupt separated the two zeolites, and called the former *desmine* and the latter *euzeolite,* thus throwing aside entirely, contrary to rule and propriety, Haüy's name *stilbite*, which should have been accepted by him in place of desmine, it being the typical part of his species. In 1822 Brooke (apparently unaware of what Breithaupt had done) used *stilbite* for the first, and named the other *heulandite.* In this he has been followed by the French and English mineralogists, while the Germans have unfortunately followed Breithaupt.

**Alt.**—Stilbite has been observed changed to quartz.

**Artif., etc.**—Lemberg shows that by digestion with potassium chloride for 13 days, stilbite is transformed into a corresponding potassium compound (Kalidesmin), while by a calcium chloride it is transformed back again, or with sodium chloride into a corresponding sodium compound (Natrondesmin). Zs. G. Ges., **28**, 559, 1876.

Doelter remarks that, like heulandite, stilbite fused and slowly cooled yields clusters of needles of a pyroxenic mineral, also often anorthite with amorphous ground-mass. Jb. Min., **1**, 132, 1890.

**Ref.**—[1] Zs. Kr., **2** 576, 1878; cf. also Langemann, Jb. Min., **2**, 132, 1886. [2] Heddle, meas. *bt* = 27°–30°, calc. 29° 25½′, Min. Mag., **4**, 44, 1880. [3] Mallet, Min. India, 125, 1887.

[4] On the optical characters, Dx., Min., **1**, 416, 1862; Lsx., l. c.; Langemann, Jb. Min., **2**, 126, 1886; Rinne, Abh. Ak. Berlin, 1175, 1890.

Foresite *Rath*, Pogg., **152**, 31, 1874.

In form and habit like stilbite. In crystalline crusts on tourmaline or lining cavities. Cleavage: *b* distinct, with pearly luster. G. = 2·405. Like stilbite in the position of the ax. pl. and bisectrix (Dx., Jb. Min., 640, 1876).

Anal.—1, Rath, l. c. 2, Bechi, D'Achiardi, Min. Tosc., **2**, 236, 1873. 3, Pulle & Capacci, quoted by D'Achiardi, Boll. Com. G., **5**, 311, 1874. 4, Sansoni, Att. Soc. Tosc., **4**, 317, 1879.

| 4. | $\frac{3}{3}$ 49·97 | 24·12 | — | 8·33 | *tr.* | — | 0·46 | — | 17·06 | = 99·94 |

D'Achiardi calls the mineral analyzed by Bechi cookeite (cuccheite).

B.B. expands and melts. With difficulty decomposed by hydrochloric acid, even after ignition. The water goes off in part at 100° to 110° C., after continued heating at 200° the mineral loses 5 to 5½ p. c., and to drive off the whole amount present (15·06 p. c. and 15·09 in two trials) a strong red heat was required.

Found at San Piero in Campo, Island of Elba, in cavities in the granite, with tourmaline, lepidolite, quartz, feldspar. It occurs, as a secondary product, along with heulandite and stilbite, covering these minerals.

Named after G. F. Forresi of Porto Ferrajo in Elba.

**444. GISMONDITE.** Zeagonite *Gismondi*, Osserv. Min. di Roma, 1816, Tasch. Min., **11**, 164, 1817. Gismondin *Leonh.*, ib., 168. Gismondine. Abrazite *Breislak*, Instit. Geol., **3**, 198. Aricite.

Monoclinic; pseudo-tetragonal by twinning' Apparent form a square octahedron with a terminal angle of 61° 30′ and an angle over the basal edge of 87° 30′ Mgc.; 61° 4′ and 88° 8′ Rath. Crystals twinned somewhat analogous to phillipsite. As explained by Rinne, the pyramid is formed by two sets of clinodomes *e* (011), twinned parallel to a prism of nearly 90°, each set being separately twinned parallel to the basal plane *c* (001). The edge of the pyramid corresponds in position, consequently, to the clino-diagonal axis. Faces rough and composite, often formed of many subindividuals.

Fracture subconchoidal. H. = 4·5. G. = 2·265. Luster vitreous. Colorless or white, bluish white, grayish, reddish. Transparent to translucent.

Optically −. $Bx_a \perp b$ (010) and $Bx_o$ sensibly $\perp a$ (100). Sections ∥ base of pyramid show four sectors, divided by diagonal lines, of which the two opposite have like extinction, while for the two adjacent the extinction-directions are inclined 5°. Sections ∥ pyramidal edge show parts ⊥ to both $Bx_a$ and $Bx_o$. Axial angles, Rinne:

$2H_{a.r} = 86° 58'$ Li $\quad 2H_{o.r} = 104° 11' \quad \therefore 2V_r = 82° 11' \quad \beta_r = 1·5348$
$2H_{a.y} = 87° 34'$ Na $\quad 2H_{o.y} = 103° 38' \quad \therefore 2V_y = 82° 43' \quad \beta_y = 1·5385$
$2H_{a.gr} = 88° 10'$ Tl $\quad 2H_{o.gr} = 102° 54' \quad \therefore 2V_{gr} = 83° 19' \quad \beta_{gr} = 1·5409$

The form was made orthorhombic by Credner; also by Lang, who regarded the crystals as made up of 110 and 011, with 110 ∧ $1\bar{1}0$ = 89° 10′, 011 ∧ $0\bar{1}1$ = 93° 41′, 110 ∧ 011 = 65° 18′. Irregularities of angle led Schrauf, and of optical character Lasaulx, to assume a twinning of triclinic individuals. Des Cloizeaux, however, while proving the forms to be penetration-twins, shows that the directions of extinction vary somewhat widely, probably as caused by the irregular grouping but not so as to confirm Lasaulx's assumption of triclinic individuals. The later observations of Rinne are given above.

Rinne finds that on increase of temperature the variations in the extinction disappear and the crystals become orthorhombic in structure; further the ax. pl. becomes parallel to a diagonal and the bisectrix coincides with $\dot{c}$. Also $2H_{a.gr}$ = 24° 57′. Optically −; double refraction weak.

**Comp.**—Uncertain; corresponds nearly to $CaAl_2Si_4O_{12} + 4H_2O$ = Silica 34·3, alumina 29·1, lime 16·0, water 20·6 = 100. Potash replaces some of the lime.

**Anal.**—1, Marignac, Ann. Ch. Phys., **14**, 46, 1845.

[a] A single determination.

**Pyr., etc.**—At 100° C. yields one-third of its water, and becomes opaque. B.B. whitens, intumesces much, and melts to a milky glass. Easily dissolves in acids and gelatinizes.

**Obs.**—Occurs in the leucitophyre or leucitic lava, of the region of Mt. Albano, south-east of Rome, at Capo di Bove, and elsewhere, associated with pyroxene, magnetite, mellilite, phillipsite, wollastonite, etc.; on the Gorner glacier, near Zermatt (Kenngott), in cavities in a coarse, granular, reddish brown garnet-rock, with epidote, calcite, chlorite, and genthite; also in the Val di Noto, Sicily (Scacchi), in white mammillary concretions, fibrous within. Other localities are: the Frauenberg near Fulda; Schiffenberg near Giessen in basalt in part altered to a clay-like substance; on the Hohenberg (Hamberg) near Bühne in Westphalia, in a nephelite-basalt in octahedral crystals of relatively large size (¾ cm. on the edge); Schlauroth near Görlitz in Silesia; Salesl, Bohemia.

A mineral near gismondite in form and like it in its complex grouping occurs with other zeolites on Fritz Island in the Schuylkill river, Penn.

*Zeagonite* is from ζεῖν, *to boil*, and ἄγονος, *barren;* and *abrazite*, from ἀ, privative, and βράζειν, *to boil*, has about the same meaning.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 1{\cdot}1451 : 1 : 0{\cdot}5906$; $\beta = 68° \, 46\tfrac{1}{4}' = 001 \wedge 100$ Miller[1].

$100 \wedge 110 = 46° \, 52'$, $001 \wedge 101 = 22° \, 3\tfrac{1}{6}'$, $001 \wedge 011 = 28° \, 50'$.

**Forms**[2]: *b* (010, *i-ì*) *m* (110, *I*) *e* ($\bar{2}$01, 2-*ì*) *r* (111, – 1)
*a* (100, *i-ī*) *c* (001, *O*) *d* (201, – 2-*ì*)[3] *f* ($\bar{6}$01, 6-*ì*)[3] *u* ($\bar{1}$11, 1)

*mm'''* = *93° 44′ *cf* = 92° 23½′ *br* = 66° 44′ *uu'* = 60° 28′
*cd* = 35° 0′ *cr* = 31° 38′ *bu* = 59° 46′ *md* = 55° 22′
*ce* = 56° 55′ *cm* = *75° 40′ *rr'* = 46° 32′ *m'e* = 66° 30′
*a'e* = *54° 19′ *cu* = 41° 57′

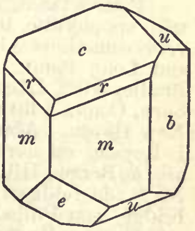
The form of laumontite approximates somewhat closely to that of the pyroxenes.

Twins: tw. pl. *a*. Common form the prism *m* with oblique termination *e*. Also columnar, radiating, and divergent.

Cleavage: *b* and *m* very perfect; *a* imperfect. Fracture uneven. Not very brittle. H. = 3·5–4. G. = 2·25–2·36. Luster vitreous, inclining to pearly upon the faces of cleavage. Color white, passing into yellow or gray, sometimes red. Streak uncolored. Transparent to translucent; becoming opaque and usually pulverulent on exposure.

Optically –. Ax. pl. ∥ *b*. $Bx_a \wedge \grave{c} = +65°$ to 70°. Dispersion large, $\rho < v$; inclined slight. Axial angles, Dx.:

Huelgoet $2E_r = 52° \, 24'$ $2E_{bl} = 56° \, 15'$



Huelgoet, Dx.

**Comp., Var.**—$H_4CaAl_2Si_4O_{14} + 2H_2O = 4H_2O.CaO.Al_2O_3.4SiO_2$ = Silica 51·1, alumina 21·7, lime 11·9, water 15·3 = 100.

*Leonhardite* is a laumontite which has lost part of its water (to one molecule), and the same is probably true of *caporcianite*. The former occurs in white or yellowish crystals like ordinary laumontite, also columnar and granular; caporcianite in pearly flesh-red monoclinic crystals. *Schneiderite* is laumontite from the serpentine of Monte Catini, Italy, which has undergone alteration through the action of magnesian solutions. It occurs with sloanite in the gabbro rosso of Tuscany. Named after Sign. Schneider, director of the mine of Monte Catini. The Ædelforsite of Retzius, or the *Red Zeolite of Ædelfors*, is referred here by N. J. Berlin, who considers it impure from mixed quartz. Bischof has analyzed a pseudomorph of laumontite after orthoclase.

| 14. | *Caporcianite* | 2·47 | 52·02 | 22·83 | 9·68 | 13·17 | MgO 1·11, $Na_2O$ 0·25, $K_2O$ 1·11 |

Laumontite loses its water of crystallization very readily and hence is often found with less than the normal amount. Malaguti and Durocher (ref., p. 571) give the following:

| Temp. | 100° | 200° | 300° | red ht. | Also | *in vac.* | $H_2SO_4$ |
|---|---|---|---|---|---|---|---|
| $H_2O$ | 3·17 p. c. | 6·08 | 7·28 | remainder | | 2·26 p. c. | 3·85 |

Leonhardite loses over sulphuric acid 1·7–1·9 p. c. water, and has then the composition of laumontite dried at 100°, Smita, l. c.

Doelter finds that laumontite, when fused and cooled very slowly, forms a semi-crystalline mass in which anorthite is prominent, also a pyroxenic mineral in acicular forms with an amorphous ground-mass. Jb. Min., **1**, 130, 1890.

**Pyr., etc.**—B.B. swells up and fuses at 2·5–3 to a white enamel. Gelatinizes with hydrochloric acid.

**Obs.**—Occurs in the cavities of basalt and similar eruptive rocks; also in porphyry and syenite, and occasionally in veins traversing clay slate with calcite. It was first observed in 1785, in the lead mines of Huelgoet in Brittany, by Gillet Laumont, after whom it is named.

Its principal localities are the Färöer Islands; Disco in Greenland; in Bohemia, at Eule in clay slate; St. Gothard in Switzerland; the Fassathal, in large masses with radiated structure; Sarnthal, near Botzen, Tyrol; the Plauenscher Grund, near Dresden; Hartfield Moss in Renfrewshire, accompanying analcite; the amygdaloidal rocks in the Kilpatrick hills, near Glasgow; the basaltic rocks of the Hebrides, and the north of Ireland. In India, in the Deccan trap area, at Poona and in the Western Ghâts.

Peter's Point, Nova Scotia, affords fine specimens of this species. It is there associated with apophyllite, thomsonite, and other species of this family; also at Port George, N. S., in veins sometimes 3 in. thick, and at Margaretville, colored green by copper; also at Digby Neck and Long Point. Also found in good specimens at Phippsburg, Maine; also sparingly at Bradleysville, Litchfield Co., Conn., near a paper-mill in narrow seams in gneiss; and at Southbury, Conn., a little east of the village, on the land of Mr. Stiles; also sparingly at West Rock, New Haven. Abundant in many places in the copper veins of Lake Superior in trap, and on I. Royale; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac. Found also at Bergen Hill, N. J., in diabase, with datolite, apophyllite, etc.; sparingly at Phillipstown, N. Y., in feldspar with stilbite; at the Tilly Foster iron mine, Brewster, N. Y.; at Columbia bridge, near Philadelphia.

*Leonhardite* occurs in a trachytic rock at Schemnitz in Hungary; at Pfitsch in an earthy chlorite, and near Predazzo in the Fleimsthal, Tyrol, in a melaphyre; in the Floitenthal. Also at Copper Falls, Lake Superior region, a variety which alters but little on exposure. *Caporcianite* occurs in geodes with calcite in the gabbro rosso of Monte de Caporciano at l'Impruneta, and other places in Tuscany. It is sometimes accompanied by native copper.

**Ref.**—[1] Mlr., Min., p. 452, 1852; he made $x = 102$, $u = 011$, $r = 111$. The position here taken is that of Dx. (Min., **1**, p. 492, 1862), but the vertical axis has half the length assumed by him. [2] Cf. Mlr., Dx., l. c. [3] J. D. D., on schneiderite from Mte. Catini, Min., p. 400, and f. 381, p. 399, 1868.

### 446. LAUBANITE. H. Traube, Jb. Min., 2, 64, 1887.

In fine fibrous, sometimes spherical, bundles with eccentric radiated structure; resembles stilbite.

H. = 4·5–5. G. = 2·23. Luster dull. Color snow-white, superficially pale yellow with iron oxide. Transparent to translucent.

**Comp.**—$Ca_2Al_2Si_5O_{15} + 6H_2O$ or $2CaO.Al_2O_3.5SiO_2 + 6H_2O$ = Silica 48·2, alumina 16·4, lime 18·0, water 17·4 = 100.

**Anal.**—Traube, l. c.

| $SiO_2$ | $Al_2O_3$ | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|
| $\frac{2}{2}$ 47·84 | 16·74 | 16·17 | 1·35 | 17·08 | FeO 0·56 = 99·74 |

**Pyr.**—B.B. fuses to a blebby glass. Decomposed by warm concentrated hydrochloric acid with separation of gelatinous silica.

**Obs.**—Occurs implanted upon phillipsite crystals in basalt at Lauban, Silesia.

## Chabazite Group. Rhombohedral.

**447. Chabazite.** **448. Gmelinite.** **449. Levynite.**

The fundamental rhombohedrons of the species of the Chabazite Group have different angles, but, as shown in the axial ratios on p. 572, they are closely related, since, taking the rhombohedron of Chabazite as the basis, that of Gmelinite has the symbol $\frac{2}{3}(20\bar{2}3)$ and of Levynite $\frac{3}{4}(30\bar{3}4)$.

The variation in composition often observed in the first two species has led to the rather plausible hypothesis that they are to be viewed as isomorphous mixtures of the feldspar-like compounds

$$(Ca,Na_2)Al_2Si_2O_8 + 4H_2O$$
$$(Ca,Na_2)Al_2Si_6O_{16} + 8H_2O$$

---

*ss′* = 107° 7′
*tt′* = 34° 6′
*iiᵛ* = 5° 55′

Twins: (1) tw. axis ć, penetration-twins (f. 2, 3, 4) very common. (2) Tw. pl. *r*, contact-twins, rare. Form commonly the simple rhombohedron varying little in angle from a cube; also *r* and *e*. Faces *r, i, e* striated ‖ intersection-edges; also *a* ‖ edge *a*/*r*. Also amorphous.

Cleavage: *r* rather distinct. Fracture uneven. Brittle. H.=4–5. G.=2·08–2·16. Luster vitreous. Color white, flesh-red; streak uncolored. Transparent to translucent. Optically −; also + (Andreasberg, also haydenite). Double refraction weak. The interference-figure usually confused; sometimes distinctly biaxial; basal sections then divided into sharply defined sectors with different optical orientation. These anomalous optical characters probably secondary and chiefly conditioned by the variation in the amount of water present. Mean refractive index 1·5, Lévy-Lcx.

The optical characters of chabazite have led Becke[3] to a hypothesis of a twinning of triclinic individuals. On this view the chabazite rhombohedron is formed of six or more individuals, each cleavable in three directions, corresponding to the rhombohedral planes, but to be taken as the pinacoids of a triclinic crystal, 100, 010, 001. The angles $\alpha$, $\beta$, $\gamma$, formed on each of these faces, respectively, between the diagonal and the extinction-directions vary for the different localities, but in a typical example (Färöer) were as follows: $\alpha = 22^\circ{\cdot}8$, $\beta = 5^\circ{\cdot}8$, $\gamma = 12^\circ{\cdot}3$. The following angles were also obtained on the cleavage form: $100 \wedge 010 = 83^\circ\ 42'$, $100 \wedge 001 = 85^\circ\ 31\tfrac{1}{2}'$, $010 \wedge 001 = 85^\circ\ 5'$.

These six or more individuals are regarded as united into double twins according to two twinning laws, the tw. planes, 110 and $1\bar{1}0$ (corresponding to faces of the prism of the second series), inclined 118·5° to each other. Three types are distinguished, according as to whether the faces taken as 100, 010, or 001 form the exterior of the pseudo-rhombohedral crystal. These three types are recognized by the angle formed by the extinction-directions in the two halves of a rhombohedral face on either side of the diagonal line. In the first type this angle is about 46°; in the second small, about 11°; in the third about 24°. A basal section shows six sectors with an arrangement of the extinctions in the different parts corresponding to these types, of which, however, the second is rare and not positively identified.

The herschelite of Sicily and seebachite of Richmond differ from chabazite in showing a small axial angle through the terminal plane; moreover, the individuals here are referred to the monoclinic system, twinned in a manner more or less closely analogous to that characterizing the chabazite proper.

Klein has described phacolite from Annerod, a basal section (‖ *c*) of which showed in parallel polarized light an optical division into six sectors; while, further, each sector was divided into two parts with extinction (‖ $\mathfrak{c}$) inclined in each symmetrically 6° to 7° to the *b*-axis between them. This direction was further the ax. plane with $Bx_{\mathfrak{a}}$ ($= \mathfrak{a}$) $\perp$ *c* the plane of the section; hence optically −; $2E = 75$–$80^\circ$ approx. These last semi-sectors were more or less sharply separated by a feather-like area between them. Different crystals and different parts of the same crystal showed wide variation in the arrangement and in the strength of the double refraction, and it is inferred that these differences are connected with a loss of the water of crystallization. This is confirmed by the behavior of a section on being heated: the heating serves to increase the strength of the double refraction, calls out the optical areas where they did not exist before or develops them in extent and distinctness. There is, however, no return to the original condition on cooling.

Rinne has investigated the effect of heat further and concludes that the optically positive chabazites, by heating and consequent loss of water, gain the optical characters of the negative varieties. Further heating changes both kinds to those with strong positive double refraction. The distinction between the optically + and − kinds in nature is hence probably connected with amount of water present.

**Var.**—1. *Ordinary.* The most common form is the fundamental rhombohedron, in which the angle is so near 90° that the crystals were at first mistaken for cubes. *Acadialite*, from Nova Scotia (*Acadia* of the French of last century), is only a reddish chabazite; sometimes nearly colorless. In some specimens the coloring matter is arranged in a tessellated manner, or in layers, with the angles almost colorless. For chabazite from Oberstein G. = 2·092, from Aussig 2·093 Streng.

*Haydenite* is a yellowish variety in small crystals from Jones's Falls, near Baltimore, Md.; the crystals are often twinned parallel to *R*.

A gelatinous substance (*adipite*) having the composition of chabazite (anal. 12) has been noted by Renevier filling cavities between calcite crystals in veins in the molasse at Crêt-Meilloret near Lausanne.

2. *Phacolite* is a colorless variety occurring in twins of mostly a hexagonal form, and often much modified so as to be lenticular in shape (whence the name, from *φακός, a bean*); the original was from Leipa in Bohemia.

Here belongs also herschelite (seebachite) from Richmond, Victoria; the composite twins of great variety and beauty. Probably also the original herschelite from Sicily made orthorhombic by v. Lang (pseudo-hexagonal by twinning). It occurs in flat, almost tabular, hexagonal prisms with rounded terminations divided into six sectors.

**Comp.**—Somewhat uncertain, since a rather wide variation is often noted even among specimens from the same locality. The ratio of $(Ca,Na_2,K_2) : Al$ is nearly constant (= 1 : 1), but of $Al_2 : Si$ varies from 1 : 3 to 1 : 5; the water also increases with the increase in silica. The composition usually corresponds to $(Ca,Na_2)Al_2Si_4O_{12} + 6H_2O$ which, if calcium alone is present, requires: Silica 47·4, alumina 20·2, lime 11·1, water 21·3 = 100. If $Ca : Na_2 = 1 : 1$, the percentage composition is: Silica 47·2, alumina 20·0, lime 5·5, soda 6·1, water 21·2 = 100.

Potassium is also present in small amount, and the Oberstein mineral contains both barium and strontium (0·48 BaO, 0·32 SrO Schröder). Streng (Ber. Oberhess. Ges., **16**, 74, 1877) explains the supposed facts most satisfactorily by the hypothesis that the members of the group are isomorphous mixtures, analogous to the feldspars of

$$\begin{cases} m(Ca,Na_2)Al_2Si_2O_8 + 4H_2O \\ n(Ca,Na_2)Al_2Si_6O_{16} + 8H_2O \end{cases}$$

If $m : n = 1 : 1$, this is equivalent to the formula above given.

[a] In desiccator 3·64 (= 1 $H_2O$), at red heat 18·62 p. c. [b] Incl. SrO 0·43.

Richmond phacolite loses 2 molecules $H_2O$ over calcium chloride after a week, Hintze, Zs. Kr., **10**, 276, 1885.

According to Damour, crystals from Dyrefiord, Iceland, and Rübendörfel, Bohemia, lost 7·2 p. c. after 5 months in dried air; after some months in the free air again regained this, and also an excess of 0·15 p. c. Heated for 1 hour to 100° C., the loss was 2·75 p. c.; to 180°, 14

p. c.; to 230°, 17 p. c.; to 300°, 19 p. c.; this loss was reduced to zero in 3 days; at a dull red heat, the loss was 21 p. c., and the mineral was no longer hygroscopic; at a bright red, it lost 22·4 p. c., intumesced, and was partially fused.

Phacolite lost 7 p. c. after 7 months in dried air; and 4 months after, in an atmosphere saturated with moisture, it had an excess of 12·5 p. c., which it lost very nearly again in ordinary air. Heated to 100° C., the loss was 3·7 p. c.; to 210°, 15·7 p. c.; to 290°–360°, 18 p. c.; and after 48 hours' exposure to the free air, the amount lost was restored. At a dull red heat, the loss was 22·2 p. c.; at a bright red, 22·8 p. c., and the material was fused to a blebby enamel.

Rg. gives as the loss to 300° 17·1 to 19·5 p. c.

The mean results obtained by Burkhardt and Hammerschlag (quoted by Streng, l. c.) are:

| 100° | 200° | 300° | ign. | strong ign. |
|---|---|---|---|---|
| 4·73 | 9·53 | 14·55 | 21·03 | 22·39 |
| 3·99 | 10·90 | 14·93 | 20·13 | 21·78 |
| 4·06 | 11·31 | 15·02 | 21·24 | 22·50 |
| 4·69 | 11·82 | 15·16 | 21·14 | 22·62 |

Hersch's results after 2 hours' heating in each case are as follows:

For *Chabazite:*

| Temp. | 102° | 125° | 155° | 195° | 240° | 260° | 290° | red ht. |
|---|---|---|---|---|---|---|---|---|
| $H_2O$ | 5·77 | 6·51 | 9·22 | 11·29 | 13·55 | 14·44 | 14·81 | 22·47 p. c. |

For *Phacolite:*

| Temp. | 100° | 150° | 195° | 240° | 285° | 320 | red ht. |
|---|---|---|---|---|---|---|---|
| $H_2O$ | 6·21 | 9·81 | 13·78 | 17·61 | 18·78 | 18·91 | 21·97 p. c. |

**Pyr., etc.**—B.B. intumesces and fuses to a blebby glass, nearly opaque. Decomposed by hydrochloric acid, with separation of slimy silica.

**Obs.**—Chabazite occurs mostly in basaltic rocks, and occasionally in gneiss, syenite, mica schist, hornblendic schist.

Occurs at the Färöer Islands, Greenland, and Iceland, associated with chlorite and stilbite; at Aussig in Bohemia, in a kind of greenstone (the *graustein* of Werner); at Oberstein, with harmotome; at Annerod, near Giessen; at the Giant's Causeway, Antrim, Kilmalcolm, Renfrewshire (some an inch across); Isle of Skye, etc.; Poona, near Bombay, India, but rare.

*Phacolite* occurs at Leipa in Bohemia; also at Salesl and Wannow, in Bohemia; in Antrim, Ireland, at Giant's Causeway.

*Herschelite* accompanies phillipsite in a lava at Aci Castello, near Aci Reale, Sicily; also at Cyclops, Catania; in basalt near Richmond, Victoria, Australia (*seebachite*), the crystals in mode of twinning and in optical properties like the Sicilian.

Both massive and incrusted at the Paugatuck stone-quarry, Stonington, Conn., with scapolite, titanite, and apatite; also yellowish red in North Killingworth, on the Essex turnpike; at Hadlyme, Conn., on gneiss; sparingly at Branchville in a pegmatyte vein with chlorite, etc.; in syenite at Somerville, Mass., also at Chester, Mass., in amygdaloid; at Bergen Hill, N. J., in small crystals; in the same rock at Piermont, N. Y.; in fissures in hornblendic gneiss at Jones's Falls, near Baltimore (*haydenite*), with heulandite. Phacolite has been reported from New York Island.

In Nova Scotia, wine-yellow or flesh-red (the last the *acadialite*), associated with heulandite, analcite, and calcite, at Five Islands, Swan's Creek, Digby Neck, Mink Cove, William's Brook.

At Husavic, Iceland, fossil clam shells (Venus) occur in a recent deposit, lined within with small rhombohedrons of chabazite. Daubrée states that crystals occur at the warm springs of Luxeuil, Dept. of Haute Saône, France, as well as at those of Plombières, under conditions which indicate that they were formed through the agency of the warm waters; the temperature at Luxeuil is 115° F., and at Plombières 163° F. Also a recent formation at Bourbonne-les-Bains and at Oran, Algiers.

The name *Chabazite* is from χαβᾶζιος, an ancient name of a stone. *Herschelite* after Sir John F. W. Herschel (1792–1871). *Seebachite* after Karl von Seebach, a German mineralogist (1839–1878).

**Alt.**—The haydenite is often covered with chlorite, and sometimes chlorite takes the place of the crystal.

Altered crystals from the Vogelsgebirge have been analyzed by Suckow, 5th Ed., p. 436.

*Doranite* of Thomson may be altered chabazite, if the analysis is not an incorrect one of the unaltered mineral. Found in basalt, 2 m. W. of Carrickfergus, Co. Antrim. Cf. 5th Ed., p. 436.

**Artif., etc.**—Obtained by Doelter (1) by recrystallization in water containing carbon dioxide; the powdered mineral was digested in a closed tube for 9 days at 150°, and minute rhombohedral crystals obtained. (2) Also with similar result by direct synthesis of freshly precipitated silica, alumina, also calcium hydrate placed in carbonated water and kept for a long time at 200° in a sealed tube. By the fusion and slow cooling of chabazite, anorthite was obtained. Jb. Min., 1, 124, 1890.

Lemberg describes the conversion of normal chabazite into the corresponding barium and potassium compounds by slow digestion with solutions of barium chloride and potassium chloride; also the resubstitution by the action of calcium chloride, Zs. G. Ges., **28**, 556, 1876.

**Ref.**—[1] Min., 138, 1823, this angle varies somewhat widely, and seldom admits of exact measurement. [2] Cf. Tamnau, Inaug. Diss., Stuttgart, 1836. Also Dx., Min., **1**, 407, 1862; Streng, Oberhess, Ges., **16**, 74, 1877; Becke, Min. Mitth., **2**, 391, 1879; Gdt., Index, **1**, 407, 1886. Gdt. with Streng includes also gmelinite and levynite. The symbol of the striated vicinal scalenohedron *i* (Ph.) is doubtful.

On the form of phacolite, herschelite, seebachite, see: Lang, Phil. Mag., **28**, 506, 1864; Ulrich, Contrib. Min. Victoria, 1870; Rath, Pogg., **158**, 387, 1876; Lsx., l. c.

$r\chi = 6° \; 2'$
$\rho\chi = 31° \; 42'$
$cq = 51° \; 57\tfrac{1}{2}'$

Twins: (1) tw. pl. *q* (30$\bar{3}$2) which corresponds in angle to the fundamental rhombohedron of the related species chabazite, see f. 6. (2) tw. axis $\dot{c}$, penetration- or contact-twins (f. 5) analogous to those of chabazite.

Crystals usually hexagonal in aspect: sometimes ρ smaller than *r*, and habit rhombohedral; *m* often horizontally striated; ρ often enclosed by the striated or channeled faces of the scalenohedron $\phi$ as in f. 5; sometimes in oscillatory combination with $r$ as in f. 3. Faces $\mathcal{E}$ striated ‖ edge $\mathcal{E}/r$ and often grooved, similarly to $\phi$.

Cleavage: *m* easy; *c* sometimes distinct. Fracture uneven. Brittle. H. = 4·5. G. = 2·04–2·17. Luster vitreous. Colorless, yellowish white, greenish white, reddish white, flesh-red. Transparent to translucent. Optically positive, Cyprus, also negative, Andreasberg, the Vicentine, and Glenarm, N. Scotia. Double refraction very weak. Interference-figure often disturbed, and basal sections divided optically into section analogous to chabazite. Refractive indices, Pirsson [1]:

| | | | |
|---|---|---|---|
| Nova Scotia | $\omega_y = 1{\cdot}4760$ | 1·4646 | 1·4770 Na |
| | $\epsilon_y = 1{\cdot}4674$ | 1·4637 | 1·4765 |

Montecchio Maggiore $\omega_y = 1{\cdot}48031$ $\epsilon_y = 1{\cdot}47852$ Negri.[3]

**Comp.**—In part $(Na_2,Ca)Al_2Si_4O_{12} + 6H_2O$. If sodium alone is present this requires: Silica 46·9, alumina 19·9, soda 12·1, water 21·1 = 100.

The above corresponds to anal. 1 (in which some lime is also present); other analyses show more silica which has been ascribed to the presence of free silica, but, as Pirsson shows, is explained by Streng's hypothesis (p. 591), the albite-like compound being present in relatively large amount.

**Anal.**—1, Rg., Pogg., **49**, 211, 1840. 2, Lemberg, Zs. G. Ges., **28**, 547, 1876. 3–5, Howe, Am. J. Sc., **12**, 270, 1876. 6, 7, Pirsson, ibid., **42**, 62, 1891.

Acording to Damour, the Cyprus gmelinite loses 6 p. c. in dried air; at 100° C. loss 13 p. c., and the amount is regained rapidly in free air; at 230° C. loss 20 p. c.; at a bright red heat 21·5 p. c., and the grains become soldered together. The Irish crystals lose 7·25 p. c. in dried air, which in six months increases to 9·3 p. c.; the loss is reduced to 1·5 p. c. after a few days of exposure. In the closed tube crumbles, giving off much water.

**Pyr., etc.**—B.B. fuses easily (F. = 2·5–3) to a white enamel. Decomposed by hydrochloric acid with separation of silica.

**Obs.**—Occurs in flesh-red crystals in amygdaloidal rocks at Montecchio Maggiore (*sarcolite* of Vauquelin) and at Castel, in the Vicentine; at Andreasberg, in argillaceous schist, with analcite and heulandite; in Transylvania; at Glenarm and Portrush in Antrim, Ireland; the island of Magee, some crystals ½ in. across; near Larne, flesh-colored; at Talisker in Skye, in large colorless crystals; on the I. of Cyprus, near Pyrgo, of a pale reddish color, and G. = 2·07.

In the United States in fine white crystals at Bergen Hill, N. J. At Cape Blomidon in Nova Scotia (*ledererite*) on the north coast, at a point nearly opposite Cape Sharp, in geodes, with analcite and quartz, often implanted on the latter mineral; also at Two Islands and Five Islands.

Named *Gmelinite* after Prof. Ch. Gmelin of Tübingen (1792–1860); *Hydrolite* from the water present; *Ledererite* after Baron Lederer, Austrian Consul at New York (d. 1842). The name hydrolite has the priority, but is objectionable because the mineral is not so eminently hydrous as to make it deserving of the appellation.

**Ref.**—[1] Pirsson, Nova Scotia, Am. J. Sc., **42**, 57, 1891. Des Cloizeaux gives for crystals from Andreasberg $mr = 50° 3'$, $rr = 67° 34'$, Min., **1**, p. 396, 1862. Streng (l. c.) shows that the forms may be referred to the chabazite rhombohedron ($rr' = 85° 16'$), since $\dot{c}$ (chabazite) = $\frac{3}{2}\dot{c}$ gmelinite; $r$ then becomes $20\bar{2}3$ ($\frac{2}{3}R$). Notwithstanding the close relation of the two species it is most unnatural to merge them in one.

[2] Cf. also Tamnau, Inaug. Diss., 1836; Guthe, Hannover Nat. Ges., **20**, 52, 1871. [3] Negri, Montecchio Maggiore, Riv. Min. Ital., **2**, 3, 1887. [4] Pirsson, Five Islands, N. Scotia, l. c.

GRODDECKITE *Arzruni*, Zs. Kr., 8, 343, 1883. Near gmelinite in form and composition. Axis $\dot{c} = 0{\cdot}7252$. In rhombohedral crystals, $mr = 50° 3\frac{1}{2}'$, $rr' = 67° 33'$; showing also a scalenohedron with terminal angles 67° 1' and 4° 30'. Cleavage: *m* indistinct. H. = 3–4. Luster vitreous. Colorless, transparent. An analysis on 0·056 gr. gave Broockmann:

$SiO_2$ 51·2 $Al_2O_3$ 12·0 $Fe_2O_3$ 7·7 CaO 1·1 MgO 3·3 $Na_2O$ [4·5] $H_2O$ 20·2 = 100

Known from a single specimen only, obtained at Andreasberg in the Harz, in 1867; the small crystals cover calcite crystals.

Named after von Groddeck, director of the Bergakademie at Clausthal.

**449. LEVYNITE.** Levyne *Brewster*, Ed. J. Sc., **2**, 332, 1825. Mesolin *Berz.*, Ed. Phil. J., **7**, 6, 1822.

Rhombohedral. Axis $\dot{c}$ = 0·8357; 0001 ∧ $10\bar{1}1$ = 43° 58¾′ Haidinger.[1]

**Forms**[1]: *c* (0001, *O*); *r* ($10\bar{1}1$, *R*); *s* ($02\bar{2}1$, − 2), *h* ($03\bar{3}1$, — 3). *cs* = 62° 37′, *ch* = 70° 57′, *ss′* = *100° 31′, *hh′* = 109° 53′, *rs* = 50° 16′, *rr′* = 73° 56′.

Twins: tw. pl. *c*, as penetration-twins. Faces *r*, *s* striated edge *r*/*s*; *c* uneven and usually rounded. Crystals often in druses.

Cleavage: *s* indistinct. Fracture subconchoidal. Brittle. H. = 4–4·5. G. = 2·09–2·16. Luster vitreous. Colorless, white, grayish, greenish, reddish, yellowish. Transparent to translucent. Optically negative. Double refraction strong.

**Comp.**—$CaAl_2Si_3O_{10} + 5H_2O$ = Silica 49·2, alumina 10·9, lime 11·5, water 18·4 = 100.

**Anal.**—1, Damour, Ann. Mines, **9**, 333, 1846. 2, 3, Hillebrand, U. S. G. Surv., Bull. **20**, 37, 1885.

| | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|
| 1. Iceland | ⅜ 44·48 | 23·77 | 10·71 | 1·38 | 1·61 | 17·41 | = | 99·36 |
| 2. Table Mt., Col., *cryst.* | 46·76 | 21·91 | 11·12 | 1·34 | 0·21 | 18·65 | = | 99·99 |
| 3. " " " *fibrous* | 46·97 | 22·39 | 10·85 | 0·79 | 1·17 | 18·03 | = | 100·20 |

Iceland crystals, according to Damour, lose 4 p. c. in dried air, and regain all again soon in the free air. When heated, begin to lose water at 70° C.; at 225° the loss is 12 to 13 p. c.; remain hygroscopic up to 360°. The loss is completed at a white heat, when the mineral is a white blebby glass.

**Pyr., etc.**—B.B. intumesces and fuses to a white blebby glass, nearly opaque. Gelatinizes with hydrochloric and nitric acids.

**Obs.**—Lines cavities in amygdaloid, and is, with rare exception, the "*sole tenant* of its druses, even though these druses be within a quarter of an inch of others containing chabazite associated with half a dozen other zeolites" (Heddle); it shows thus its distinctiveness from chabazite.

Found at Glenarm and at Island Magee, Antrim; near Dungiven, Magilligan, and elsewhere in Londonderry; Hartfield Moss, near Glasgow; at Dalsnypen, Färöer (the original locality) and on the Island Waagö; at Godhavn, Disco Island, Greenland; at Onundarfiord, Dyrefiord, and elsewhere in Iceland. In the basalt of Table Mountain near Golden, Colorado.

*Mesolin* is a white granular mineral from the Färöer, which may be chabazite; it fills small cavities in amygdaloid.

Named after the mineralogist and crystallographer A. Lévy, author of the work on the Heuland Cabinet.

**Ref.**—[1] Ed. J. Sc., 2, 332, 1828. The form may be referred to the chabazite rhombohedron (*rr′* = 85° 16′), since $\dot{c}$ (chabazite) = $\frac{4}{3}\dot{c}$ levynite approx., then *r* = $30\bar{3}4$ (¾ *R*), *s* = $03\bar{3}2$ (− $\frac{3}{2}$ *R*), *h* = $09\bar{9}4$ (− $\frac{9}{4}$ *R*).

---

**450. ANALCITE.** Zeolite dure (fr. Etna) *Dolomieu*, F. de St. Fond Min. des Volcans, 198, 1784. Würfelzeolith pt. [rest Chabazite] *Emmerling*, Min., 205, 1793; Lenz, 1, 241, 1794. [Form, f. 9, described.] Zeolite cubique, Z. leucitique, *Delameth.*, T. T., 2, 307, 308, 1797. Analcime *H.*, Tr., 3, 1801. Analcite *Gallitzin*, Dict. Min., 12, 1801. Euthalite *Dx.*, Min., **2**, p. xxxix, 1874. Euthallite. Eudnophit *Weibye*, Pogg., **79**, 303, 1850.

Isometric. Observed forms[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *r* (332, $\frac{3}{2}$)[2] *n* (211, 2-2) *ω* (*hll*, *m-m*)[3].

Usually in trapezohedrons (f. 1); also in cubes with planes *n* (f. 3); again the cubic faces replaced by the vicinal trisoctahedron *ω*. Sometimes in composite groups (f. 2) about a single crystal as nucleus (f. 4). Also massive granular; compact with concentric structure.

Cleavage: cubic, in traces. Fracture subconchoidal. Brittle. H. = 5–5·5.

G. = 2·22–2·29; 2·278 Thomson. Luster vitreous. Colorless, white; occasionally grayish, greenish, yellowish, or reddish white. Transparent to nearly opaque. Often shows weak double refraction which is connected with loss of water and consequent change in molecular structure. Refractive index: $n_r = 1·4874$, Cyclopean Is., Dx.[3]

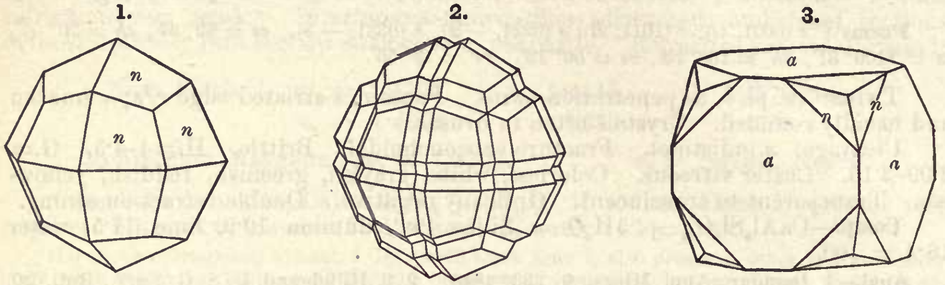

Fig. 1, Common form. 2, 4, Phœnix mine, L. Superior, Penfield. 3, Cyclopean Is., Fassathal.

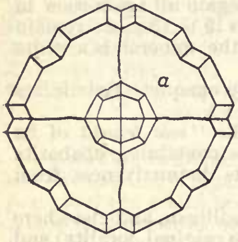
The question of the optical anomalies of analcite (early noted by Brewster) and the system to which it should be referred, has been discussed by many authors[4]. Schrauf on crystallographic grounds referred crystals from Friedeck, Bohemia, to the orthorhombic system, describing them as complex twins, analogous to leucite. Mallard described in detail the optical anomalies of the species, and explained them by assuming that a crystal was formed by the interpenetration of three pseudo-tetragonal individuals, each one formed of two orthorhombic crystals, with nearly equal axes; these 24 orthorhombic crystals, composing a single pseudo-isometric crystal, would correspond to the 24 planes of a tetrahexahedron.

4.



The whole subject was exhaustively reviewed and further investigated by Ben Saude. He described the results of an optical examination of sections of many crystals cut parallel to the cubic, octahedral, dodecahedral, and trapezohedral planes, and showed that they do not correspond with Mallard's hypothesis, but can be explained on the supposition of internal tension. He found, further, that gelatine cast into moulds corresponding to the crystalline forms acquired on solidifying similar optical characters. He further showed that the effect of heat was to increase the strength of the double refraction or to call it out in parts before isotropic. Klein went far to explain this fact and the double refraction in general by proving that heated in an atmosphere of water vapor or in hot water analcite became isotropic, while dry heat increased the double refraction. The optical anomalies, then, are immediately connected with the loss of water and the change in molecular arrangement resulting from that.

Rinne has also investigated the effect of heat; he calls the form resulting from ignition a triclinic soda-leucite; optically determined, each of the pseudo-quadratic chief sectors, whose axes coincide with the cubic axes, is made up of four sectors with the bisectrix (−) of each inclined about 4° to these axes. An analogy is suggested in optical character and molecular symmetry between ordinary potash-leucite and this soda-leucite on the one hand, and monoclinic potash feldspar and triclinic soda feldspar, albite, on the other.

**Comp.**—$NaAlSi_2O_6 + H_2O = Na_2O.Al_2O_3.4SiO_2.2H_2O$ = Silica 54·5, alumina 23·2, soda 14·1, water 8·2 = 100.

Doelter writes the formula $H_2NaAlSi_2O_7$ or $NaAlSiO_4 + 2H_2SiO_3$, arguing that the water cannot be water of crystallization.

*Picranalcime* of Meneghini and Bechi (Am. J. Sc., **14**, 62, 1852), supposed to contain 10 p. c. MgO, is nothing but ordinary analcite as shown by Bamberger, anal. 7.

[a] Given as $K_2O$ 10·56, $Na_2O$ 2·00.

[b] In original 25·59, which makes the sum 102·87, while that given is 100·87.

Hersch (l. c.) has determined the loss of water on heating (after two hours in each case) as follows:

| Temp. | 100° | 150° | 195° | 245° | 295° | red ht. |
|---|---|---|---|---|---|---|
| $H_2O$ · | — | 0·20 | 0·75 | 2·13 | 5·61 | 8·29 p. c. |

*Euthallite* of Esmark is a compact analcite, often in nodular form with concentric structure, the successive layers greenish or grayish white in color. It results from the alteration of elæolite. Occurs on the islands Lille Arö, Sigtesö, and at other points on the Langesund fiord, southern Norway. Cf. Dx., l. c., Pisani, anal. 20; also Bgr., Zs. Kr., **16**, 223, 1890. Named from εὖ, *well*, and θαλλός, *a green twig*, in allusion to the color.

*Eudnophite* of Weibye, from the island Låven in the Langesund fiord, Norway, has been regarded as dimorphous with analcite, belonging to the orthorhombic system. The description given is as follows: Crystals in six-sided prisms (*b*, *m*) terminated by a macrodome, *e*, with the angles *mm'''* = 60°, *me* = 50°. ∴ *ee'* = 95° 50'. Commonly massive, cleavable. Cleavage: *c* perfect; *a*, *b*, less so. H. = 5·5. G. = 2·27. Luster weak, a little pearly on the cleavage-faces. Color white, grayish, brownish. Streak white. Translucent; in thin laminæ transparent. Optically biaxial; negative. 2E = 70° approx. Cf. Weibye, l. c.; Dx., Min., **1**, 395, 1862; Btd., Bull. Soc. Min., **4**, 239, 1881; Dx., ibid., **7**, 78, 1884; Lcx., ibid., **8**, 359, 1885.

Brögger (Zs. Kr., **16**, 565 *et seq.*, 1890) has thoroughly investigated this supposed species, especially on the optical side, and concludes that it is nothing but ordinary analcite, characterized by more than usually strong double refraction; cf. above.

**Pyr., etc.**—Yields water in the closed tube. B.B. fuses at 2·5 to a colorless glass. Gelatinizes with hydrochloric acid.

**Obs.**—The Cyclopean Islands, near Catania, Sicily, afford pellucid crystals; also the Fassathal in Tyrol; other localities are, in Scotland, in the Kilpatrick Hills; Bowling, pseudomorphs after laumontite; Glen Farg; near Edinburgh; at Kilmalcolm; the Campsie Hills, etc.; Co. Antrim, etc., in Ireland; the Färöer Islands; Iceland; the Vincentine, with prehnite, chabazite, apophyllite, etc.; Wessela, near Aussig, Bohemia; at Arendal, in Norway, in beds of iron ore; at Andreasberg, in the Harz, in silver mines; Kangerdluarsuk, Greenland; Kerguelen Is. On the islands of the Langesund fiord, Norway, in part as a result of the alteration of elæolite; also of ægirite.

*Euthallite* (see above) is from Lille Arö, Sigtesö, and other points in the Langesund fiord, southern Norway. *Eudnophite* (see above) is from the island Låven (Lamö) in the same region and occurs with catapleiite, leucophanite, mosandrite, etc. Named from εὐδνοφος, *obscurity*, in allusion to the cloudiness of the mineral.

Occurs at Bergen Hill, New Jersey; in gneiss near Yonkers, Westchester Co., N. Y.; at Perry, Maine, with apophyllite, in greenstone; abundant in fine crystals, with prehnite, datolite, and calcite, in the Lake Superior region; in the gangue of the copper, at Copper Falls and Northwestern mines, and at Michipicoton Island, and also at other mines not now worked. At Table Mt. near Golden, Colorado, with other zeolites.

Nova Scotia affords fine specimens at Martial's Cove, Five Islands, Cape d'Or, Swan's Creek, and Cape Blomidon.

The name *Analcime* is from ἀναλκις, *weak*, and alludes to its weak electric power when heated or rubbed. The correct derivative is *analcite*, as here adopted for the species.

**Alt.**—Sauer describes analcite altered from leucite and changed further to feldspathic pseudomorphs. Analcite altered to a mixture of calcite and hydrous silicate of aluminium has been observed by Tschermak. Also occurs altered to prehnite; to lithomarge.

**Artif.**—Obtained by de Schulten in trapezohedral crystals, showing double refraction like the natural mineral; the method employed consisted in heating to 180°–190° in a closed tube sodium silicate, or caustic soda with an aluminous glass. The crystals were trapezohedrons (0·1 mm.) and gave on analysis: $SiO_2$ 54·6, $Al_2O_3$ 21·8, $Na_2O$ [15·0], CaO *tr.*, $H_2O$ 8·6 = 100. Also by heating in a similar manner, sodium silicate and aluminate in proper proportion to form analcite, with lime water; these crystals were sensibly isotropic. The author concludes that a concentrated alkaline solution gives trapezohedrons, under other conditions cubes are formed. Bull. Soc. Min., 3, 150, 1880, **5**, 7, 1882.

Lemberg (l. c.) shows that a soda solution changes leucite (anal. 1) into analcite, while the product so formed (anal. 2) may be altered back again into leucite (anal. 3). A similar result was obtained with natural analcite.

| | $SiO_2$ | $Al_2O_3$ | CaO | $K_2O$ | $Na_2O$ | $H_2O$ |

Kr., **16**, 565 *et seq.*, 1890; Rinne, Ber. Ak. Berlin, 1188, 1890.

The *Cluthalite* of Thomson (Min., **1**, 339, 1836) occurs in flesh-red vitreous crystals in amygdaloid at the Kilpatrick Hills. H. = 3·5. G. = 2·166. Opaque or subtranslucent. Fragile. Analysis afforded:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Na_2O$ | MgO | $H_2O$ |
|---|---|---|---|---|---|
| 51·27 | 23·56 | 7·31 | 5·13 | 1·23 | 10·55 = 99·05. |

It may be altered analcite. From Clutha, a name sometimes given to the valley of the Clyde. Cf. Btd., Bull. Soc. Min., **4**, 239, 1881.

### 451. FAUJASITE. *Damour*, Ann. Mines, **1**, 395, 1842.

Isometric. In octahedrons; also a trisoctahedron perhaps 655 ($\frac{6}{5}$-$\frac{6}{5}$)[1]. Twins: tw. pl. *o*, usually penetration-twins.

Cleavage: *o* distinct. Fracture uneven. Fragile. H. = 5. G. = 1·923. Luster vitreous; sometimes adamantine. Colorless, white; brown externally.

Exhibits anomalous double refraction, which has given rise to doubt as to its true form.

Rinne[2] shows that it is normally isotropic, but a loss of a little water disturbs the molecular structure and the octahedron is then divided into eight uniaxial individuals, optically +. At about 150° C., after losing twelve molecules, it is again isotropic, while a further loss of water makes it uniaxial and negative. On taking up water again it returns to the positive uniaxial condition.

**Comp.**—Perhaps $H_4Na_2CaAl_4Si_{10}O_{38} + 18H_2O = Na_2O.CaO.2Al_2O_3.10SiO.20H_2O$ = Silica 46·8, alumina 15·9, lime 4·4, soda 4·8, water 28·1 = 100.

**Anal.**—1, Damour, l. c.; 2, id., ib., **14**, 67, 1848.

| | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|
| 1. Kaiserstuhl | 49 36 | 16·77 | 5·00 | 4·34 | 22·49 = 97·96 |
| 2. " | 46·12 | 16·81 | 4·79 | 5·09 | 27·02 = 99·83 |

According to Damour, loses 15 p. c. of water when exposed for one month to dry air, but regains almost all of it in ordinary air in 24 hours. Heated at 50°–55° C. for one hour loses 15·2 p. c.; at 60°–65°, 10·4 p. c.: at 70°–75°, 19·5 p. c., which is almost entirely regained by exposure to air for a few weeks.

Jannasch found that the loss over fused $CaCl_2$ was 1·83 p. c. in 24 hours, 1·72 in 48 hours;

over $H_2SO_4$ 4·69 in 54 hours, 6·75 in 78, 6·52 in 100, 5·84 in 106; over $P_2O_5$ 7·44 in 118, 9·04 in 142, 10·19 in 166, 10·88 in 190 hours. From here on the weight became constant. Again, the loss after heating several hours from 105° to 110° was 10·88 p. c.; at 150°, 16·83, corresponding to 12 molecules of water, and this was reabsorbed by the air. Further at 160° the loss was 18·66 p. c.; 200° to 205°, 21·41; 250° to 260°, 22·67; over a gas burner 27·02 and over a blast lamp 27·59. Jb. Min., **2**, 24, 1887.

**Pyr., etc.**—B.B. fuses with intumescence to a white blebby enamel. Decomposed by hydrochloric acid without gelatinization.

**Obs.**—Occurs with augite in the limburgyte of Sasbach in the Kaiserstuhl, Baden. Also stated to occur at Annerod near Giessen; Pflasterkaute near Eisenach; probably also Stempel near Marburg (Koenen). The adamantine luster sometimes observed is attributed to a thin bituminous coating. Named by Damour after Faujas de Saint Fond.

**Ref.**—[1] Knop, Lieb. Ann., **111**, 375, 1859. [2] Jb. Min., **2**, 17, 1887.

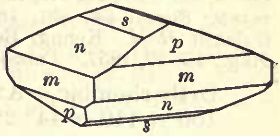
**452. EDINGTONITE.** *Haidinger*, Brewster's Ed. J. Sc., **3**, 316, 1825. Antiedrit *Breith.*, Char., 164, 1832.

Tetragonal, with sphenoidal hemihedrism. Axis $\dot{c} = 0{\cdot}6725$; 001 ∧ 101 = 33° $55\frac{1}{4}'$, Haid[1].

**Forms**[1]: *m* (110, *I*); sphenoids *p* (111, 1), *s* (113, $\frac{1}{3}$)[2], *n* ($1\bar{1}2$, $\frac{1}{2}$).

Angles: *mp* = 46° 26′, *m′n* = 64° 34′, *m′s* = 72° 25′ (meas. 72°), *pp′* 111 ∧ $\bar{1}\bar{1}1$ = 87° $7\frac{1}{2}'$ (meas. 87°19′), *nn′* ($1\bar{1}2$ ∧ $\bar{1}12$) = *50° 52′, *ss′* = 35° $1\frac{1}{2}'$.

Form as in the figure. Crystals minute (not above $\frac{3}{8}$ in. across) and inconspicuous. Faces *s* rare and slightly curved. Also massive.



Haidinger.

Cleavage: *m* perfect. Fracture subconchoidal to uneven. Brittle. H. = 4–4·5. G. = 2·694 Heddle; 2·71 Turner. Luster vitreous. White, grayish white, pink. Translucent to opaque. Optically negative, Dx.

**Comp.**—Perhaps (Rg.) $BaAl_2Si_3O_{10} + 3H_2O$ or $BaO.Al_2O_3.3SiO_2.3H_2O$ = Silica 36·8, alumina 20·9, baryta 31·3, water 11·0 = 100.

**Anal.**—Heddle, Phil. Mag., **9**, 179, 1855.

$SiO_2$ 36·98 $Al_2O_3$ 22·63 BaO 26·84 CaO,$Na_2O$ *tr.* $H_2O$ 12·46 = 98·91.

Turner's original analysis (1825) was incomplete and incorrect; a new investigation is needed.

**Pyr., etc.**—Yields water, and becomes white and opaque. B.B. at a high heat fuses to a colorless mass. Affords a jelly with hydrochloric acid.

**Obs.**—Occurs in the Kilpatrick Hills, near Glasgow, Scotland, associated with harmotome, another barium mineral, and also analcite, prehnite, calcite, etc. Haidinger states that the crystals examined by him occurred on thomsonite, an association not observed by Heddle.

Named after Mr. Edington, who found it in 1823 on Lord Blantyre's estate near Old or West Kilpatrick, Dumbartonshire. It has since been found at several quarries in the neighborhood but, perhaps in part because so inconspicuous, it is a very rare mineral in collections.

**Artif.**—Lemberg mentions a silicate obtained by digesting an artificial natrolite 12 days with barium chloride, which is near edingtonite; it yielded: $SiO_2$ 37·50, $Al_2O_3$ 21·85, BaO 25·38, CaO 1·17, $Na_2O$ 1·04, $H_2O$ 13·06 = 100. Zs. G. Ges., **28**, 553, 1876.

**Ref.**—[1] l. c., also Pogg., **5**, 193, 1825. [2] Greg. Min., 191, 1858.

*Glottalite* of Thomson (Min., **1**, 328, 1836), from Port Glasgow, on the Clyde, Scotland, is described as occurring in white crystals that "seem to be regular octahedrons; at least 4-sided pyramids, the faces of which appear to be equilateral triangles, are visible; other crystals appear to be cubic." H. = 3·5; G. = 2·18; luster vitreous. Thomson obtained, l. c.:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | $H_2O$ | |
|---|---|---|---|---|---|
| 37·01 | 16·31 | 0·50 | 13·93 | 21·25 | = 99·00 |

Heddle states (Phil. Mag., **9**, 181, 1855) that it is probably edingtonite mixed with harmotome, mentioning that Thomson's mineral came from the same locality with the edingtonite, and from the same dealer that furnished him with the edingtonite for his analysis. In the mineralogy of Greg and Lettsom (p. 171, 1858) it is stated to be chabazite occurring in small aggregated and irregular crystals, somewhat resembling phacolite.

## Natrolite Group.

### 453. Natrolite. 454. Scolecite. 455. Mesolite.

The Natrolite Group includes the sodium silicate, Natrolite, with the empirical formula $Na_2Al_2Si_3O_{10}.2H_2O$; the calcium silicate, Scolecite, $CaAl_2Si_3O_{10}.3H_2O$; also Mesolite intermediate between these and corresponding to $\left\{ \begin{array}{l} m Na_2Al_2Si_3O_{10}.2H_2O \\ n CaAl_2Si_3O_{10}.3H_2O \end{array} \right.$.

These three species agree closely in angle, though varying in crystalline system; Natrolite is orthorhombic usually, also rarely monoclinic; Scolecite is monoclinic, perhaps also in part triclinic; Mesolite seems to be both monoclinic and triclinic.

*dd'* = 61° 5′
*zz'* = 73° 16′
*yy'* = 27° 51′
*ff'* = 36° 0′
*at* = 30° 25′
*as* = 44° 22½′
*ao* = 71° 11′
*oo''* = 53° 39′

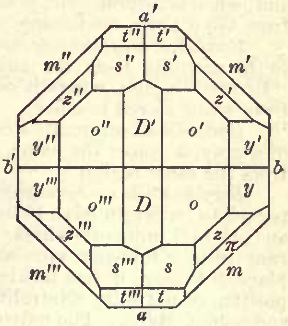
*ay* = 76° 4½′
*oo'''* = *36° 47½′
*dd'''* = 59° 39′
*zz'''* = 71° 27′
*ss'''* = 26° 58′
*yy'''* = 89° 52′
*ff'''* = 130° 16′

Also in part monoclinic with the axial ratio $\grave{a} : \overset{+}{b} : \dot{c} = 1{\cdot}0165 : 1 : 0{\cdot}35991$; $\beta = 89° \ 54\frac{5}{8}'$ Brögger[7].

Forms: *a* (100, *i-ī*), *b* (010, *i-ì*), *n* (210, *i-2̄*), *m* (110, *I*), *e* (1̄01, 1-ī), *D* (011, 1-ì), *o* (111, −1), *o′* (1̄11, 1), *d* (2̄21, 2), *z* (3̄31, 3), *y* (3̄11, 3-3), *s* (1̄31, 3-3̀), *t* (1̄51, 5-5̀), *Π* ($\bar{3}\bar{6}{\cdot}34{\cdot}1$, 36-$\frac{18}{17}$).

The crystals are regarded as monoclinic twins with *a* as tw. plane; the axes $\grave{a}$ and $\overset{+}{b}$ correspond respectively to $\bar{b}$ and $\breve{a}$ of the orthorhombic type. The optical orientation is sensibly the same for both types.

4.



Monte Baldo, after Artini.

Stadtländer[8] has described complex natrolite crystals from Marburg whose grouping may be explained by assuming a twinning with the prism as tw. pl. and *c* as comp. face, the horizontal axes thus crossing at angles of nearly 90°. Further a twinning about the front pinacoid is also suggested, but with some question. Luedecke[8] notes a variation in extinction of 5°–7° with the prismatic edge in natrolite of Aussig and Salesl.

Twins: tw. pl.[3] *u* (301), cruciform twins, rare; the crystals crossing nearly at right angles—this may perhaps have been an accidental association. Crystals prismatic, usually very slender to acicular and terminated by the pyramid *o* (111), then closely resembling tetragonal forms; often with more or less distinct vicinal planes; the faces in the prismatic zone vertically striated. Crystals frequently interlacing, divergent, or in stellate group. Also fibrous, radiating, massive, granular, or compact.

Cleavage: *m* perfect; *b* imperfect, perhaps only a plane of parting (Bgr.). Fracture uneven. H. = 5–5·5. G. = 2·20–2·25; 2·249, Bergen Hill, Brush. Luster vitreous, sometimes inclining to pearly, especially in fibrous varieties. Color white, or colorless; to grayish, yellowish, reddish to red. Transparent to translucent.

Optically +. Ax. pl. ∥ *b*. Bx ⊥ *c*. Indices and axial angles:

Auvergne $\alpha_r = 1{\cdot}4768$ $\beta_r = 1{\cdot}4797$ $\gamma_r = 1{\cdot}4887$ $\therefore 2V_r = 59° \ 29'$ $2E_r = 94° \ 27'$ Dx.
Also $2E_r = 93° \ 28'$ $2E_{bl} = 95° \ 41'$

Bombiano $2H_{a.y} = 62° \ 32'$ $2H_{o.y} = 119° \ 28'$ $\therefore 2V_y = 62° \ 0'$ Artini
*Savite* $2H_{a.y} = 62° \ 44'$ $2H_{o.y} = 119° \ 38'$ $\therefore 2V_y = 62° \ 6'$ "

Stokö $2H_{a.r} = 62° \ 31'$ $2H_{o.r} = 119° \ 35\frac{1}{2}'$ $\therefore 2V_r = 61° \ 56'$ Bgr.
$2H_{a.y} = 62° \ 44'$ $2H_{o.y} = 119° \ 4'$ $\therefore 2V_y = 62° \ 15'$
$2H_{a.gr} = 63° \ 0\frac{1}{2}'$ $2H_{o.gr} = 118° \ 37'$ $\therefore 2V_{gr} = 62° \ 34'$

$\alpha_r = 1{\cdot}47287$ $\beta_r = 1{\cdot}47631$ $\gamma_r = 1{\cdot}48534$ (calc.)
$\alpha_y = 1{\cdot}47543$ $\beta_y = 1{\cdot}47897$ $\gamma_y = 1{\cdot}48866$
$\alpha_{gr} = 1{\cdot}47801$ $\beta_{gr} = 1{\cdot}48172$ $\gamma_{gr} = 1{\cdot}49181$
Also calc. ($\alpha$, $\beta$, $\gamma$) $2V_r = 61° \ 3'$ $2V_y = 62° \ 10'$ $2V_{gr} = 62° \ 19'$

Sections of crystals, regarded as monoclinic, gave:

$2H_{a.r} = 61° \ 29'$ $2H_{o.r} = 121° \ 1'$ $2V_r = 60° \ 51'$ Bgr.
$2H_{a.y} = 61° \ 37'$ $2H_{o.y} = 120° \ 47'$ $2V_y = 61° \ 0\frac{1}{2}'$
$2H_{a.gr} = 61° \ 46'$ $2H_{o.gr} = 120° \ 24'$ $2V_{gr} = 61° \ 13\frac{1}{2}'$

Dispersion horizontal, probably shown in sections ⊥ $Bx_a$ ($Bx_a \parallel \dot{c}$ approx.); but crossed dispersion not observed in sections ⊥ $Bx_o$.

Other determinations of indices and axial angles are given by Brögger, quoted from Lorenzen; further the latter found: 2E = 98° 58′ at 15°, 97° 6′ at 108°, 96° 13′ at 150°, 93° 21′ at 229½°, 90° 55′ at 308°. Cf. also Dx., N. R., 74, 1867.

Rinne (cf. p. 571) shows that with increase of temperature and the accompanying loss of water, natrolite is converted into a monoclinic substance, called by him *metanatrolite*. A section ∥ *c* with extinction parallel the diagonals (𝔞 ∥ $\breve{a}$ and 𝔟 ∥ $\bar{b}$) showed, after heating, fields with the extinction (𝔞) inclined to each other 15° in adjacent parts about the lateral axis; further, to correspond with the new molecular structure, the former vertical axis must be made the axis of symmetry, and the prismatic faces orthodomes 101 and $\bar{1}01$, with twinning about 100 (or 001). No change in geometrical form accompanied the change in molecular structure.

**Var.**—*Ordinary.* Commonly either (*a*) in groups of slender colorless prismatic crystals, varying but little in angle from square prisms, often acicular, or (*b*) in fibrous divergent or radiated masses, vitreous in luster, or but slightly pearly (these radiated forms often resemble those of thomsonite and pectolite); often also (*c*) solid amygdules, usually radiated fibrous, and somewhat silky in luster within; (*d*) rarely compact massive.

*Galactite* is ordinary natrolite, occurring in colorless acicular crystallizations in southern Scotland, instituted as a species on an erroneous analysis. It may contain a few per cent of lime and hence is intermediate between pure natrolite and mesolite (p. 605). *Fargite* is a red natrolite from Glen Farg, containing, like galactite, about 4 p. c. of lime.

*Radiolite, bergmannite, spreustein, brevicite, palæo-natrolite,* are names which have been given to the natrolite from the augite-syenite of southern Norway, on the Langesund fiord, in the "Brevik" region, where it occurs fibrous, massive, and in long prismatic crystallizations, and from white to red in color.

*Radiolite* as originally described occurred in radiated masses, and compact fibrous nodules, of a grayish color; the name, however, is often used to include also the well crystallized forms from the same region.

*Bergmannite* or *Spreustein* is a secondary mineral in the augite-syenite. Various views in regard to its origin have been expressed; for example Scheerer regarded it as a paramorph after an original mineral which he called *palæo-natrolite;* other authors have suggested elæolite, cancrinite, a feldspar, etc., as the parent mineral. Brögger, however, shows that, in the first place, it is more or less lacking in homogeneity and, further, includes kinds which have the composition of natrolite (Natrolith-spreustein, Bgr.) and others of hydronephelite (Hydronephelit-spreustein, Bgr.). The natrolite spreustein has arisen chiefly from the alteration of sodalite, also in less extent from cancrinite. A similar change of sodalite to natrolite (spreustein) has also been noted in connection with the sodalite-syenite of Kangerdluarsuk, Greenland.

*Brevicite* is the same as spreustein, though the name has also been used as synonymous with radiolite. The original analysis (anal. 27), showing nearly 7 p. c. CaO, was probably not made on homogeneous material, cf. anals. 19, 28. *Crocalite,* from the Ural, is a red zeolite, like the bergmannite of Laurvik; occurs in small amygdules, and is fibrous or compact.

*Savite,* according to Sella (N. Cimento, 1858) is natrolite, occurring in slender colorless prisms. It comes from a serpentine rock at Mte. Caporciano, Italy, and specimens are ordinarily not pure from serpentine. Its identity with natrolite has been confirmed by Dx. (N. R., 75, 1867); also more fully by Artini[6]. Cf. anal. 5.

*Iron-natrolite* (Eisennatrolith *Bergm.*, Jernnatrolith *Swed.*) is a dark green opaque variety, either crystalline or amorphous, from the Brevik region; probably from the islands Lövö and Sigtesö. It was supposed to have the alumina to a considerable extent replaced by iron sesquioxide, cf. anal. 31. Brögger shows, however, that the iron is due to the presence of inclusions of a mineral probably related to stilpnomelane.

**Comp.**—$Na_2Al_2Si_3O_{10} + 2H_2O$ or $Na_2O.Al_2O_3.3SiO_2 + 2H_2O$ = Silica 47·4, alumina 26·8, $Na_2O$ 16·3, water 9·5 = 100.

Groth writes the formula as a basic metasilicate, $Na_2(AlO)Al(SiO_3)_3 + 2H_2O$.

The Auvergne natrolite undergoes, according to Damour (ref., p. 571), no loss in dried air. At 240° C. it loses nearly all its water and becomes milky and opaque; and if afterward exposed to the free air, it regains all it had lost, excepting its transparency and firm texture; if again heated, it loses its water at about 90° C.

Hersch (l. c.) obtained, after heating two hours at each temperature:

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Temp. | 105° | 130° | 160° | 195° | 225° | 240° | 265° | 290° | red. ht. |
| $H_2O$ | 0·14 | 0·17 | 0·19 | 0·27 | 0·37 | 0·64 | 0·77 | 2·51 | 9·81 p. c. |

**Pyr., etc.**—In the closed tube whitens and becomes opaque. B.B. fuses quietly at 2 to a colorless glass. Fusible in the flame of an ordinary stearine or wax candle. Gelatinizes with acids.

**Obs.**—Occurs in cavities in amygdaloidal basalt, and other related igneous rocks; sometimes in seams in granite, gneiss, and syenite.

It is found in the *graustein* of Aussig and Teplitz in Bohemia; in fine crystals at Puy de Marman and Puy de la Piquette in Auvergne; at Alpstein, near Sontra in Hesse; Fassathal, Tyrol; Monte Baldo on Lago di Garda, Montecchio Maggiore, and other points in Venetian Italy; Kapnik in Hungary; Dellys in Algeria; Högau in Würtemberg (the Faserzeolith *W.*), in yellowish radiated masses; etc. In red amygdules (*crocalite*) in amygdaloid of Ireland, Scotland, and Tyrol; the amygdaloid of Bishopton (*galactite*), acicular crystals, several inches long; at Glen Farg in Fifeshire; in Dumbartonshire; at Glenarm in the county of Antrim; at Portrush; and at Magee Island, near Larne, Ireland. Common in the augite-syenite of the Langesund fiord, near Brevik, southern Norway, in fine crystallizations, also in radiated forms and as the secondary spreustein (see further above).

In North America, natrolite occurs in the trap of Nova Scotia, at Gates's mountain, Cape d'Or, Swan's Creek, Cape Blomidon, Two Islands. At Bergen Hill, N. J.; sparingly at Chester, Ct.; at Copper Falls, Lake Superior, in crystals, sometimes on native copper; also on New York Island; at Magnet Cove, Arkansas (anal. 13).

Named *Mesotype* by Haüy, from *μέσος, middle*, and *τυπος, type*, because the form of the crystal—in his view a square prism—was intermediate between the forms of stilbite and analcite. *Natrolite*, of Klaproth, is from *natron, soda;* it alludes to the presence of soda, whence also the name *soda-mesotype*, in contrast with scolecite, or *lime-mesotype*. Schumacher's name *bergmannite*, after Bergmann (1735–1784), dates from the same year (1801) with Haüy's *mesotype*.

**Artif.**—Obtained by Doelter by recrystallization of the powdered mineral in water containing carbon dioxide in a closed tube at 160°. Further by digesting nephelite in a closed tube at 200° with alkaline carbonates and carbonated water, analcite was obtained in distinct crystals, and also prismatic crystals which were inferred to be natrolite. Jb. Min., 1, 134, 1890.

Lemberg shows that the slow (5 months) action of potassium carbonate on natrolite causes an exchange of potassium for sodium, which action is reversed by sodium carbonate. The action of calcium chloride brought about a partial change toward scolecite in natural natrolite, but complete in the artificial substance. Zs. G. Ges., **28**, 551, 1876.

**Ref.**—[1] Arö, Langesund fiord (?), Zs. Kr. **3**, 478, 1879, also [7] below; cf. Luedecke, Jb. Min., **2**, 7, 1881. Artini and Brögger also obtained the axial ratios:

| | $\breve{a}$ | $\bar{b}$ | $\grave{c}$ | |
|---|---|---|---|---|

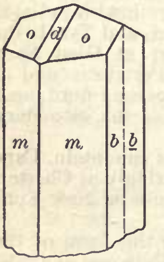
It is shown by Luedecke that part of the scolecite deviates optically from the requirements of the monoclinic system; here belongs the mineral from the Schattige Wichel, etc.

Crystals slender prismatic, twins with *a* as tw. pl., showing a feather-like striation on *b*, diverging upward at 15°–22° Zeph. (24°–26° Dx.); also as penetration-twins. Faces *m* often delicately striated horizontally. Crystals in divergent groups. Also massive, fibrous and radiated, and in nodules.



Iceland, Flink.

Cleavage: *m* nearly perfect. H. = 5–5·5. G. = 2·16–2·4. Luster vitreous, or silky when fibrous. Transparent to subtranslucent. Pyroelectric: on heating, the end with *oc* +, also *a* +, prisms and *b* —.

Optically —. Double refraction weak. Ax. pl. and $Bx_o \perp b$. $Bx_a \wedge \grave{c} = 15°–16°$. Axial angles, Schmidt[5]:

| | | | | |
|---|---|---|---|---|
| Iceland | $2H_{a.r} = 32° 26'$ Li | $2H_{o.r} = 124° 1'$ | ∴ | $2V_{a.r} = 35° 22'$ |
| | $2H_{a.y} = 33° 48'$ Na | $2H_{o.y} = 123° 0'$ | ∴ | $2V_{a.y} = 36° 26'$ |
| | $2H_{a.gr} = 34° 10'$ Tl | $2H_{o.gr} = 121° 26'$ | ∴ | $2V_{a.gr} = 37° 14'$ |
| Also measured | $2E_y = 55° 44'$ | ∴ $\beta = 1·4952$ | | |

**Comp.**—$CaAl_2Si_3O_{10} + 3H_2O$ or $CaO.Al_2O_3.3SiO_2.3H_2O$ = Silica 45·9, alumina 26·0, lime 14·3, water 13·8 = 100.

According to Damour, Iceland columnar masses lost nothing in dried air; nothing until the heat applied exceeded 100° C.; at 300° it had lost 5 p. c., which it regained in moist air; at a dull red heat the loss was 12 p. c., and it was no longer hygroscopic; at a bright red it lost 13·9 p. c., and became after intumescence a white enamel.

Hersch (l. c.) has obtained the following results, after two hours' heating in each case:

| Temp. | 105° | 130° | 160° | 195° | 225° | 290° | red ht. |
|---|---|---|---|---|---|---|---|
| $H_2O$ p. c. | — | 0·14 | 1·13 | 3·98 | 4·39 | 4·78 | 13·86 p. c. |

**Pyr., etc.**—B.B. sometimes curls up like a worm (whence the name from σκώληξ, *a worm*, which gives *scolecite*, and not *scolesite* or *scolezite*); other varieties intumesce but slightly, and all fuse at 2–2·2 to a white blebby enamel. Gelatinizes with acids like natrolite.

**Obs.**—Occurs in the Berufiord, Iceland, where the crystals often exceed two inches in length, and are occasionally a quarter of an inch thick. It has also been met with in amygdaloid at Staffa; in the Isle of Mull; in Skye, at Talisker; near Eisenach in Saxony; near the Viesch Glacier, Valais; common in fine crystallizations in the Deccan trap area, in British India, near Poona, and from railroad tunnels and cuttings in the Bhor Ghât; in Greenland; at Pargas, Finland; in Auvergne; the valley of Cachayual, in Chili; the Serra de Tuberão, Santa Catharina, Brazil.

In the United States, in *Colorado* at Table Mountain near Golden in cavities in basalt.

In Canada, at Black Lake, Megantic Co., Quebec, in a granite dike in the serpentine region.

**Artif.**—Obtained by Doelter in a manner analogous to other zeolites by recrystallization in a closed tube at 150°. See Jb. Min., **1**, 135, 1890. Lemberg shows that scolecite may be converted into natrolite (and mesolite) by the slow action of soda solutions, Zs. G. Ges., **28**, 551, 1876.

**455. MESOLITE.** *Fuchs & Gehlen*, Schw. J., **8**, 353, 1813, **18**, 16, 1816. Mesotype pt. Fibrous Zeolite pt. Mehl-Zeolith pt. Lime-and-Soda Mesotype. Antrimolite *Thom.*, Min., **1**, 326, 1836. Harringtonite *Thom.*, ibid., 328.

Monoclinic and triclinic[1] In prismatic crystals near scolecite in form and angles, and twinned like them. Prismatic angle about 88°. Lateral planes often vertically striated. In more or less divergent groups or tufts, often very delicate. Also massive; nodules or masses usually silky fibrous or columnar; often bristled with capillary crystals; sometimes consisting of interlaced fibres; rarely stalactitic, radiated fibrous within; occasionally cryptocrystalline, porcelain-like.

Des Cloizeaux describes crystals which are twins and show variations in extinction-directions which throw them into the triclinic system, Min., **1**, 388, 1862. Brazilian crystals, examined by Hussak, are also complex twins and apparently triclinic.

Cleavage: prismatic, perfect. Brittle, but tough when cryptocrystalline. H. = 5. G. = 2·2–2·4; 2·39, Iceland. Luster of crystals vitreous; of fibrous masses more or less silky. Color white or colorless, grayish, yellowish. Transparent to translucent; opaque, when amorphous.

**Var.**—Besides (*a*) the ordinary acicular and capillary crystallizations, divergent tufts (less delicate commonly than those of natrolite, but sometimes downy), and fibrous nodules or masses, mesolite occurs (*b*) in fibrous stalactites, with the fibers radiating from the center—the variety called *Antrimolite* by Thomson, from Antrim, Ireland, having H. = 3·5–4. G. = 2·096; also (*c*) amorphous, chalk-white, like an almond in luster, opaque and tough, with H. = 5–5·5, and G. = 2·21, the variety named *Harringtonite* by Thomson, also from Antrim; G. = 2·174, Haughton.

*Galactite* (p. 602) is intermediate between natrolite and ordinary mesolite.

**Comp.**—Intermediate between natrolite and scolecite and corresponding to $\left\{\begin{matrix} m\mathrm{Na_2Al_2Si_3O_{10}.2H_2O} \\ n\mathrm{CaAl_2Si_3O_{10}.3H_2O} \end{matrix}\right.$. The ratio between these two compounds varies somewhat. If, as often, $\mathrm{Na_2 : Ca} = 1 : 2$, the percentage composition is: Silica 46·4, alumina 26·3, lime 9·6, soda 5·3, water 12·4 = 100.

[a] At 100° 1·41 p. c.

**Pyr., etc.**—Yields water in the closed tube. B.B. becomes opaque, swells up into vermicular forms, but not in so marked a manner as scolecite, fusing easily to a blebby enamel. Gelatinizes with hydrochloric acid (Fuchs).

**Obs.**—Occurs in amygdaloid and related rocks. The fibrous kinds, especially the coarser, are usually a little less smoothly or neatly fibrous than those of natrolite. On Skye, in delicate interlacing crystals called *cotton-stone*, and in feathery tufts, and in solid masses consisting of radiating crystals; in downy tufts and other forms at Naalsö, Färöer; also with chabazite in Eigg; near Edinburgh and Kinross, and at Hartfield Moss, in Scotland; in Antrim, at the Giant's Causeway, in acicular crystallizations; also at Ballintoy in Antrim, stalactitic (*antrimolite*), investing yellow calcite, or chabazite; in Antrim, in veins of amorphous mesolite (*harringtonite*), at Portrush and at the Skerries; and at Magee Island, and Agnew's Hill, 5 m. W. of Larne. In cavities in the basalt of the Pflasterkaute, near Eisenach (Credner, Jb. Min., 59, 1860, Luedecke, l. c.) with thomsonite, gismondite, phillipsite, etc. In augite-porphyryte in the Serra de Botucatú, Brazil; also at other localities, as stated above.

In the United States with other zeolites on Fritz island in the Schuylkill R., Penn.; in the basalt of Table Mt. near Golden, Colorado, with other zeolites. In the North Mountain of King's Co., and Gates's Mountain, of Annapolis Co., N. Scotia, with faröelite, in masses, sometimes large (one reported as large as a man's head), usually within fine fibrous, radiated, and somewhat plumose; also at Cape Blomidon.

**Ref.**—[1] Made triclinic by Dx. on optical grounds (Min., 1, p. 388), the crystals being penetration-twins and a section ∥ *c* being divided into four sectors with extinction-directions inclined 11° to 15° in those adjacent, but alike for those opposite. Luedecke (Jb. Min., 2, 28, 1881; Zs. Nat. Halle, 63, 42, 1890) has attempted to establish an orthorhombic, a monoclinic, and a triclinic variety; the first being galactite from Bishoptown (which, however, is more naturally placed under natrolite); the second the mesolite from Iceland and Pflasterkaute; the third the crystals from an unknown locality described by Des Cloizeaux. Schmidt (Zs. Kr., 11, 594, 1886), however, argues that it is probably monoclinic like scolecite.

$p$ (111, 1)

1. 2.

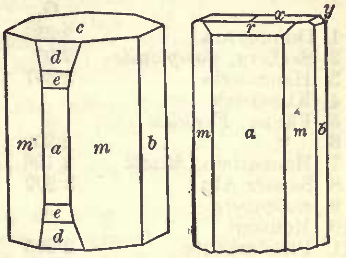

Fig. 1, Kilpatrick, Greg & Lettsom.
2, Norway, Brögger.

The axial ratio (as noted by Bgr.) deviates but little from the isometric system; cf. the angles for $p$ below.

$mm''' = 89° \; 37'$
$rr' = 90° \; 46'$
$ar = {}^*44° \; 37'$
$dd' = 152° \; 17'$
$ee' = 165° \; 56'$
$xx' = 2° \; 24'$
$yy' = 53° \; 26'$
$cy = {}^*26° \; 43'$

$pp' = 71° \; 4\frac{1}{2}'$
$pp'' = 110° \; 0\frac{1}{2}'$
$pp''' = 70° \; 31'$
$pp^{iv} = 69° \; 59\frac{1}{2}'$
$ap = 54° \; 28'$
$bp = 54° \; 44'$
$cp = 55° \; 0'$

Distinct crystals rare; in prisms with prismatic faces strongly striated vertically. Commonly columnar, structure radiated; in radiated spherical concretions; also closely compact.

Cleavage: $b$ perfect; $a$ less so; $c$ in traces. Fracture uneven to subconchoidal. Brittle. H. = 5–5·5. G. = 2·3–2·4. Luster vitreous, more or less pearly. Snow-white; reddish, green; impure varieties brown. Streak uncolored. Transparent to translucent. Pyroelectric. Optically +. Ax. pl. ∥ $c$. Bx ⊥ $b$. Dispersion $\rho > v$ strong. Axial angles, Dx.:

Dumbarton $2E_r = 82°–82° \; 18'$ $2E_{bl} = 84° \; 11'–84° \; 42'$
Seeberg $2H_{a.r} = 55° \; 22'$ $2H_{o.r} = 132° \; 26'$ $\therefore 2V_r = 53° \; 50'$ $2E_r = 85° \; 47'$ $\beta_r = 1{\cdot}503$ Dx.
Mte. Somma $2E_r = 86°$ $2E_{bl} = 89° \; 53'$
Fassathal $2E_r = 93° \; 25'$ $2E_{bl} = 96° \; 53'$

**Var.**—1. *Ordinary*. ($a$) In regular crystals, usually more or less rectangular in outline, prismatic in habit. ($b$) Prisms slender, often vesicular to radiated. ($c$) Radiated fibrous. ($d$) Spherical concretions, consisting of radiated fibers or slender crystals. Also massive, granular to impalpable, and white to reddish brown, less often green as in *lintonite*, anal. 15, 16. The spherical massive forms also radiated with several centers and of varying colors, hence of much beauty when polished.

*Ozarkite* is a white massive thomsonite (as shown by Smith and Brush), either granular or compact, with G. = 2·24, from Arkansas.

2. *Mesole* (*Faröelite* of Heddle), the original from the Färöer, occurs in spherical concretions, consisting of lamellar radiated individuals, pearly in cleavage. It occurs with mesolite and apophyllite, and contains a little more silica than normal thomsonite. Mesole was long since referred to thomsonite by Haidinger.

*Scoulerite* R. D. Thomson, from Portrush, Antrim, is mesole in structure.

3. *Chalilite* Thomson is a compact variety, of a reddish brown color, from the Donegore Mts., Antrim, cf. 5th Ed., p. 425.

**Comp.**—$(Na_2,Ca)Al_2Si_2O_8 + \frac{5}{2}H_2O$ or $(Na_2,Ca)O.Al_2O_3.2SiO_2.\frac{5}{2}H_2O$. The ratio of $Na_2 : Ca$ varies from 3 : 1 to 1 : 1. Percentage composition:

| | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|
| $Ca : Na_2 = 3 : 1$ | 37·0 | 31·4 | 12·9 | 4·8 | 13·9 | = 100 |
| “ “ = 2 : 1 | 36·9 | 31·4 | 11·5 | 6·4 | 13·8 | = 100 |
| “ “ = 1 : 1 | 36·8 | 31·3 | 8·6 | 9·5 | 13·8 | = 100 |

Mesole shows a little more silica, and the same is true of some other varieties, and it does not seem possible to explain this, in all cases, by the assumption of free quartz.

[a] Probably a little too high.

The Mittelgebirge mineral changes but slightly in moist or dry air, according to Damour; after two hours at 280° C. it loses 6·1 p. c., and very slowly regains the water lost in the open air, the loss being reduced to 1·5 p. c. after forty hours. At a red heat the loss is 13·3 p. c., and the mineral becomes fused to a white enamel.

Hersch (l. c., anal. 6) obtained the following results after two hours' heating in each case:

| Temp. | 100° | 150° | 195° | 240° | 305° | red ht. |
|---|---|---|---|---|---|---|
| $H_2O$ | 1·61 | 3·68 | 4·84 | 5·58 | 7·95 | 14·98 p. c. |

Also for “ mesolith,” anal. 7:

| Temp. | 100° | 160° | 200° | 250° | 300° | red ht. |
|---|---|---|---|---|---|---|
| $H_2O$ | 2·43 | 3·19 | 4·93 | 5·99 | 7·92 | 14·50 p. c. |

**Pyr., etc.**—B.B. fuses with intumescence at 2 to a white enamel. Gelatinizes with hydrochloric acid.

**Obs.**—Found in cavities in lava and other igneous rocks, sometimes with elæolite as a result of its alteration.

Occurs near Kilpatrick, and at Kilmalcolm and Port Glasgow, Scotland, in amygdaloid; in the lavas of Somma (*comptonite*); in basalt at the Pflasterkaute in Saxe Weimar; at Seeberg and elsewhere in Bohemia, in the cavities of phonolyte; in the Cyclopean islands, Sicily, with analcite and phillipsite; on the islands, Låven, Arö, etc., in the Langesund fiord, also Klokkerholmen near Brevik, Norway; in the Färöer; in phonolyte at Hauenstein, Bohemia; in Hungary, near Schemnitz; at Theiss, Tyrol; at Mt. Monzoni, Fassathal; in straw-yellow needles (*carpholstilbite*) at the Berufiord, Iceland, G. = 2·362.

Long, slender, prismatic crystallizations, of a grayish white color, are obtained at Peter's Point, Nova Scotia, where it is associated with apophyllite, mesotype, laumontite, and other related minerals. In the U. S., occurs fibrous radiated and massive (*ozarkite*) at Magnet Cove, in the Ozark Mts., Arkansas, in cavities in elæolite (from the alteration of which it has apparently resulted), with slender prisms of apatite. Also in the amygdaloid of Grand Marais, L. Superior, which yields the water-worn pebbles on the shores of the lake; they are in part white porcelain-like, in part fibrous radiated with several centers, and showing zones of green, red, and white; also fine granular, of a green color (*lintonite*), anal. 15, 16; named from Miss Laura A. Linton. In the basalt of Table Mt. near Golden, Colorado.

*Mesole* is from the cave of Nalsö, island of Färö; Disco I., Greenland; Annaklef, Sweden, a few miles west of C. Blomidon, Bay of Fundy, near the small village of Ft. George.

**Alt.**—The Mte. Somma comptonite is partially altered, involving a loss of water, assumption of $CaCO_3$, and a change in the amounts of silica and alumina. Analyses by E. Scacchi gave:

| $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $H_2O$ | $CO_2$ |
|---|---|---|---|---|---|
| 41·18 | 12·22 | 38·01 | 2·04 | 1·79 | 1·79 = 99·95 |
| 39·17 | 35·99 | 14·65 | 2·87 | 5·77 | [1·55] = 100 |

Acc. Napoli, Dec. 12, 1888, the analyses corrected by Cathrein, Zs. Kr., **18**, 101, 1890.

Lemberg has shown that solutions of potassium and sodium carbonate in 3½ months accomplished an exchange of potassium and sodium respectively for most of the calcium, but more rapidly in the former case. Further the potash compound so formed is largely reconverted into the original mineral by treatment with calcium chloride. Zs. G. Ges., **28**, 555, 1876.

Doelter shows that by slow cooling after fusion, a crystalline mass is obtained, consisting of distinct anorthite crystals, chiefly twins. This corresponds with the formula above accepted (Rg.) by which it is essentially a hydrate of anorthite.

**Ref.**—[1] Låven, Langesund fiord, Norway, **16**, 641, 1890; also earlier, Zs. Kr., **2**, 289, 1879. [2] See Bgr., l. c., cf. also Greg, Min., 158, 1859, Dx., Min., **1**, 374, 1862. Also perhaps 705, Phillips, but doubtful; cf. Gdt., Index, **3**, 205, 1891. Luedecke, l. c., gives $0\cdot1\cdot50$ (= *x*) on thomsonite from the Pflasterkaute. Twins, resembling harmotome, are mentioned by Guthe, JB. Ges. Hann., **14**, 47, 1864.

PICROTHOMSONITE *Meneghini & Bechi*, Am. J. Sc., **14**, 63, 1852. Picrotonsonite *Ital.* Like thomsonite in form, and near it in composition. The soda is replaced by magnesia, and possibly as a result of alteration. Occurs in radiated masses, laminated in structure; H. = 5; G. = 2·278; luster pearly; white; transparent in small fragments; very fragile. Analysis, Bechi:

$SiO_2$ 40·36 $Al_2O_3$ 31·25 MgO 6·26 CaO 10·99 $Na_2O,K_2O$ 0·29 $H_2O$ 10·79 = 90·94

B.B. fuses to a white enamel, with intumescence. Dissolves in cold acids and gelatinizes. Occurs with caporcianite in the gabbro rosso of Tuscany. The name, from πικρός, *bitter*, and *thomsonite*, alludes to the magnesia present.

**457. HYDRONEPHELITE.** *F. W. Clarke*, Am. J. Sc., **31**, 265, 1886.

Ranite. Rauit S. R. Paijkull, Inaug. Diss., Ber. Ch. Ges., **7**, 1334, 1874. Rauite *wrong orthog.* Hydronephelit-spreustein *Brögger*, Zs. Kr., **16**, 234, 1890.

Probably hexagonal. In massive forms, with radiated structure.

H. = 4·5–6. G. = 2·263 Clarke; 2·48 Paijkull. Luster vitreous. Color white; also dark gray to grayish black. Translucent to nearly opaque. Optically uniaxial, positive.

**Comp., Var.**—For hydronephelite $HNa_2Al_3Si_3O_{12} + 3H_2O$ or $2Na_2O.3Al_2O_3.6SiO_2.7H_2O$ = Silica 39·3, alumina 33·4, soda 13·5, water 13·8 = 100.

Ranite is $(Na_2,Ca)Al_2Si_2O_8 + 2H_2O$, which is equivalent to $\overset{I}{R}_3Al_3Si_3O_{12} + 3H_2O$ like hydronephelite. Calcium is present with the sodium.

**Anal.**—1, F. W. Clarke, l. c. 2, Paijkull, l. c.

| | G. | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. *Hydronephelite* | 2·263 | 38·99 | 33·62 | 0·07 | 13·07 | 1·12 | 12·98 = 99·85 |
| 2. *Ranite* | 2·48 | 39·21 | 31·79 | 5·07 | 11·55 | — | 11·71 $Fe_2O_3$ 0·57 = 99·90 |

Other analyses of hydronephelite on material slightly impure gave results similar to those quoted.

**Pyr., etc.**—Fusible easily to a white enamel. Soluble in hydrochloric acid with gelatinization.

**Obs.**—*Hydronephelite* is from Litchfield, Maine, where it occurs intimately mixed with sodalite, from the alteration of which it has been derived.

*Ranite* occurs on the island Låven (also called Lamö) in the Langesund fiord, Norway, where it has been formed from the alteration of elæolite. Named for the old Norse sea-god, Ran. Brögger shows that it includes part of what has passed under the name of *spreustein*, see also p. 602.

## APPENDIX TO ZEOLITES.

**Chlorastrolite** *C. T. Jackson; J. D. Whitney*, J. Nat. Hist. Boston, **5**, 488, 1847. Shown by Hawes not to be a homogeneous mineral. An analysis gave:

$SiO_2$ 37·41, $Al_2O_3$ 24·62, $Fe_2O_3$ 2·21, FeO 1·81, MgO 3·46, CaO 22·20, $Na_2O$ 0·32, $H_2O$ 7·72 = 99·75, Am. J. Sc., **10**, 25, 1875.

Referred by Hawes to prehnite, but by Lacroix to thomsonite on optical grounds, Bull. Soc. Min., **10**, 147, 1888. It occurs in small rounded pebbles with finely radiated or stellated structure and of a light bluish green color. H. = 5·5. G. = 3·180. Found on the shores of Isle Royale, Lake Superior, derived from the trap. Named from χλωρός, *green*, ἄστρον, *star*, λίθος, *stone.*

**Zonochlorite** *A. E. Foote*, Rep. Amer. Assoc., 65, 1873; App. II, 63. Similar to chlorastrolite. Hawes (Am. J. Sc., **10**, 24, 1875) obtained from an analysis of a dark green specimen: $SiO_2$ 35·94, $Al_2O_3$ 19·41, $Fe_2O_3$ 6·80, FeO 4·54, MgO 2·48, CaO 22·77, $Na_2O$ *tr.*, $H_2O$ 8·40 = 100·34. Microscopic examination showed the presence of green earthy particles as impurities disseminated through a white mineral. From the amygdaloid of Neepigon Bay, Lake Superior.

**Dolianite** *English collectors; Dx.*, Min., **1**, 435, 1862. *A. Lacroix*, Bull. Soc. Min., **8**, 356, 1885. A doubtful zeolitic mineral, stated to come from Knock Station, Ayrshire, Scotland. Occurs in cone-shaped masses with fan-shaped lamellar structure; cleavage basal, easy; soft; luster pearly; color white. Optically uniaxial, negative.

B.B. fuses with some difficulty to a white enamel. Analysis, author unknown:

$SiO_2$ 53·24 $Al_2O_3$ 35·46 CaO 5·73 MgO 0·02 $H_2O$ 4·04 = 98·49

**Episphärite** *A. Knop*, Zs. Kr., **18**, 668, 1891. An undetermined zeolitic mineral occurring in white spherical forms with radiated fibrous structure on natrolite in the phonolyte of Oberschaffhausen, Kaiserstuhl.

**Sasbachite** (Saspachite) *J. Schill*, Jb. Min., 452, 1846, Dx., Min., **1**, 420, 1862. A zeolitic mineral from Sasbach in Kaiserstuhl, afforded J. Schill: $SiO_2$ 51·50, $Al_2O_3$ 16·51, CaO 6·20, $K_2O$ 6·82, MgO 1·93, $H_2O$ 17·00 = 99·96. Occurs in tufts of fibers and concretions; G. = 1·465; H. = 4–5; white or colorless; luster silky to vitreous. Easily soluble in hydrochloric acid. Occurs in doleryte in cavities, and is often overlaid by faujasite and apophyllite.

**Sloanite** *Meneghini & Bechi*, Am. J. Sc., **14**, 64, 1852. Orthorhombic. Cleavage: prismatic (75°) very distinct. In radiated masses with transverse fracture. H. = 4·5. G. = 2·441. Luster pearly. White. Opaque.

Analysis, Bechi, l. c.:

$SiO_2$ 42·19 $Al_2O_3$ 35·00 CaO 8·12 MgO 2·67 $Na_2O$ 0·25 $K_2O$ 0·03 $H_2O$ 12·50 = 100·76

B.B. fuses without intumescence to a white enamel. Dissolves in acids even in the cold, and gelatinizes. From the gabbro rosso of Tuscany. Named after Mr. Sloane, proprietor of the Mte. Catini mine.

**Unknown Zeolite** *O. Beyer*, Min. Mitth., **10**, 31, 1888. In spherical forms and crusts, showing minute crystals (hexagonal?). H. = 4·5. G. = 2·162. Analysis, O. Beyer:

$SiO_2$ 57·50 $Al_2O_3$ 18·11 CaO 4·63 MgO 1·20 $K_2O$ 6·98 $Na_2O$ 2·40 $H_2O$ 10·48 = 101.30

Only slightly attacked by acids. Occurs in amygdaloidal cavities in slag-like inclusions of the basalt of the Grossdehsaer Berg.

---

## II. Mica Division.

The species embraced under this Division fall into three groups: 1, the **Mica Group**, including the Micas proper; 2, the **Clintonite Group**, or the Brittle Micas; 3, the **Chlorite Group**. Supplementary to these are the Vermiculites, hydrated compounds chiefly results of the alteration of some one of the micas.

All of the above species have the characteristic micaceous structure, that is, they have highly perfect basal cleavage and yield easily thin laminæ. They belong to the monoclinic system, but the position of the bisectrix in general deviates but little from the normal to the plane of cleavage; all of them show on the basal section plane angles of 60° or 120°, marking the relative position of the chief zones of forms present, and giving them the appearance of hexagonal or rhombohedral symmetry; further, they are more or less closely related among themselves in the angles of prominent forms.

The species of this Division all yield water upon ignition, the micas mostly from 4 to 5 p. c., the chlorites from 10 to 13 p. c.; this is probably to be regarded in all cases as water of constitution, and hence they are not strictly *hydrous* silicates.

More or less closely related to these species are those of the Serpentine and Talc Division and the Kaolin Division following, many of which show distinctly a mica-like structure and cleavage and also pseudo-hexagonal symmetry.

---

### 1. Mica Group. Monoclinic.

| | | | |
|---|---|---|---|
| 458. | **Muscovite** | Potassium Mica | $H_2KAl_3(SiO_4)_3$ |

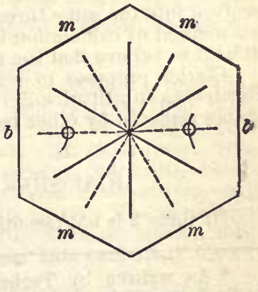
| | | Magnesium Mica; usually containing fluorine, nearly free from iron. | |
| 462B. | **Lepidomelane** | Annite | |
| | | Iron Micas. Contain ferric iron in large amount. | |

The species of the MICA GROUP crystallize in the monoclinic system[1], but with a close approximation to either rhombohedral or to orthorhombic symmetry; the plane angles of the base are in all cases 60° or 120°. They are all characterized by highly perfect basal cleavage, yielding very thin, tough, and more or less elastic laminæ. The negative bisectrix, $\mathfrak{a}$, is very nearly normal to the basal plane, varying at most but a few degrees from this; hence a cleavage plate shows the axial interference-figure, which for the pseudo-rhombohedral kinds is often uniaxial or nearly uniaxial. Of the species named above, biotite has usually a very small axial angle, and is often sensibly uniaxial; the axial angle of phlogopite is also small, usually 10° to 12°; for muscovite, paragonite, lepidolite the angle is large, in air commonly from 50° to 70°.

The Micas may be referred to the same fundamental axial ratio with an angle of obliquity differing but little from 90°; they show to a considerable extent the same forms, and their isomorphism is further indicated by their not infrequent intercrystallization in parallel position, as biotite with muscovite, lepidolite with muscovite, etc.

A blow with a somewhat dull-pointed instrument on a cleavage plate of a mica develops in all the species a six-rayed *percussion-figure*[2] (f. 1), two lines of which are parallel to the prismatic edges, the third, which is the most strongly characterized (Leitstrahl *Germ.*), is parallel to the clinopinacoid or plane of symmetry. The micas are often divided into two classes, according to the position of the plane of the optic axes. In the *first class* belong those kinds for which the optic axial plane is normal to *b* (010), the plane of symmetry (f. 1); in the *second class* the axial plane is parallel to the plane of symmetry. The percussion-figure serves to fix the crystallographic orientation when crystalline faces are wanting. A second series of lines at right angles to those mentioned may be more or less distinctly developed

1.



by pressure[3] of a dull point on an elastic surface, forming the so-called *pressure-figure;* this is sometimes six-rayed, more often shows three branches only, and sometimes only two are developed. In f. 1 the position of the pressure-figure is indicated by the dotted lines. These lines are connected with gliding-planes inclined some 67° to the plane of cleavage (see beyond).

The micas of the *first class* include: Muscovite, paragonite, lepidolite, also some rare varieties of biotite called anomite.

The *second class* embraces: Zinnwaldite and most biotite, including lepidomelane and phlogopite.

Chemically considered, the micas are silicates, and in most cases orthosilicates, of aluminium with potassium and hydrogen, also often magnesium, ferrous iron, and in certain cases ferric iron, sodium, lithium (rarely rubidium and cæsium); further, rarely, barium, manganese, chromium. Fluorine is prominent in some species, and titanium is also sometimes present. Other elements (boron, etc.) may be present in traces. All micas yield water upon ignition in consequence of the hydrogen (or hydroxyl) which they contain.

The composition of the micas is still involved to a greater or less degree in uncertainty, and although much light has been thrown upon the subject in recent years, it is impossible to give general formulas, for all the different species, which do not rest to a greater or less extent upon hypothesis[4].

Tschermak explains the composition of the micas by regarding them as isomorphous mixtures of the following fundamental molecules:*

$$K = H_2KAl_3Si_3O_{12} \qquad M = Mg_6Si_3O_{12} \qquad S = H_4Si_6O_{12}$$

Of these, K corresponds to ordinary muscovite; M is a hypothetical polymere of chrysolite, and S a hypothetical silicon hydroxide which may also take the form $Si_5F_{12}O_4$. In K other ratios may exist between the hydrogen and potassium, e.g., $K'' = HK_2Al_3Si_3O_{12}$, etc.; also the potassium may be replaced by sodium and lithium; further, the aluminium by ferric iron (and chromium). Also the magnesium in M may be replaced by ferrous iron and manganese. As briefly summarized by the author the composition is as follows:

Ordinary Muscovite, as already stated, corresponds to the simple orthosilicate formula, $H_2KAl_3Si_3O_{12}$. Some kinds, however, are more acidic and are interpreted as equivalent to $3H_2KAl_3Si_3O_{12} + H_4Si_5O_{12}$.

Lepidolite corresponds to $3K_3Al_3Si_3O_{12} + Si_5F_{12}O_4$, with the potassium one-half replaced by lithium and the fluorine by hydrogen.

Zinnwaldite is $(K,Li)_3Al_3Si_3O_{12},Fe_5Si_3O_{12},Si_5(F,H)_{12}O_4$ in the ratio of 10 : 2 : 3.

Ordinary Biotite ("Meroxene") is $HKAl_2Si_2O_8$ and $Mg_4Si_2O_8$ in the ratio of 1 : 1, 2 : 1, and intermediate ratios.

For the "Anomite" analyzed the composition is assumed $HK_2Al_3Si_3O_{12},Mg_6Si_3O_{12}$, also in the ratios from 1 : 1 to 2 : 1.

Lepidomelane is $H_2KAl_3Si_3O_{12}$ and $Mg_6Si_3O_{12}$, with the aluminium largely replaced by ferric iron.

Phlogopite is regarded as containing the molecules $K_3Al_3Si_3O_{12},Mg_6Si_3O_{12},H_4Si_5O_{12}$ (or $Si_4F_{12}O_4$), often in the ratio 3 : 4 : 1.

For the fuller discussion of the subject and the process of calculation by which these supposed fundamental molecules are deduced, reference is made to the original memoirs.

Rammelsberg[4] regards the micas as containing the three silicates $R_2SiO_3$, $R_4SiO_4$, $R_6SiO_5$ in various molecular relations, e.g., Muscovite is $R_4SiO_4 + Al_4Si_3O_{12}$; the more acidic kinds are $R_{14}Si_4O_{15} = R_2SiO_3 + 3R_4SiO_4$, which is further written $m\overset{I}{R}_{14}Si_4O_{16} + n\overset{II}{R}_7Si_4O_{16} + p\overset{III}{R}_{14}Si_{12}O_{45}$, in which $m : n : p = 5 : 1 : 5$, $7 : 1 : 7$, $9 : 1 : 9$ in different cases. Similarly the other micas are resolved into the same three silicates, and the ratios in which they enter are calculated. That this method of calculation is applicable to any silicate, however complex, is obvious, but it is difficult to believe that the results reached really give the true constitution of the compounds.

Clarke[4] proposes to regard all the orthosilicate micas (as indeed other aluminous orthosilicates) as substitution derivatives of $Al_4(SiO_4)_3$, in which the aluminium is more or less completely replaced by other metals, the possible types being:

$$\begin{array}{ccc} 1. & 2. & 3. \\ \overset{I}{R}_3Al_3(SiO_4)_3 & \overset{I}{R}_6Al_2(SiO_4)_3 & \overset{I}{R}_9Al(SiO_4)_3 \end{array}$$

Of these 2 is not essential, since it may be resolved into equal molecules of 1 and 3. Here

---

* As written by Tschermak, these have the double form, $K = H_4K_2Al_6Si_6O_{24}$, etc., and similarly beyond.

$\overset{I}{R}$ represents a univalent metal, as H,K,Na,Li, or a univalent radical, as MgF,$AlF_2$,AlO. Further, type 1 is obviously equivalent to $\overset{I}{R}\overset{II}{R}Al_3(SiO_4)_3$, or again to $\overset{II}{R}_3Al_6(SiO_4)_6$, where $\overset{II}{R}$ = Mg,Fe,Mn, etc.; similarly for the others.

Under these types may be embraced, then, all the orthosilicate micas, those with fluorine being assumed to contain the group MgF (or $AlF_2$), and those with an excess of oxygen the univalent group AlO.

For the more acid micas, the assumption is made that, analogous to the feldspars, they contain polysilicic acid, $H_4Si_3O_8$, which is tetrabasic like orthosilicic acid. For this there would be types similar to these above, so that the composition of a given mica would be expressed:

$$\begin{array}{ccc} 1. & 2. & 3. \\ \left\{\begin{array}{l} mR_3Al_3(SiO_4)_3 \\ nR_3Al_3(Si_3O_8)_3 \end{array}\right. & \left\{\begin{array}{l} mR_6Al_2(SiO_4)_3 \\ nR_6Al_2(Si_3O_8)_3 \end{array}\right. & \left\{\begin{array}{l} mR_9Al(SiO_4)_3 \text{ etc.} \\ nR_9Al(Si_3O_8)_3 \end{array}\right. \end{array}$$

Or representing $SiO_4$ and $Si_3O_8$ by X, the micas then would fall within the limits of $\overset{I}{R}_3Al_3X_3$ and $R_9AlX_3$.

The application to muscovite will explain this: Ordinary muscovite is $H_2KAl_3(SiO_4)_3$ conforming to type 1 above where $R_3 = H_2K$; the acidic muscovites (phengite of Tschermak) are regarded as molecular mixtures of

$$H_2KAl_3(SiO_4)_3 \quad \text{and} \quad H_2KAl_3(Si_3O_8)_3$$

Again normal lepidolite is a metasilicate, but (p. 311) metasilicic acid is equivalent to combined molecules of ortho- and polysilicic acid: $2H_2SiO_3 = H_4SiO_4 + H_4Si_3O_8$.

Further, since the Li and $AlF_2$ vary somewhat with the silica and hence seem to be connected with $Si_3O_8$, normal lepidolite is resolved into

$$HKLiAl_3(SiO_4)_3 + (AlF_2)_3K_3Li_3Al(Si_3O_6)_3$$

The view of Clarke has the advantage that it assumes only one hypothetical molecule, which, moreover, is analogous to known compounds which play an important part in the Feldspar Group.

**Artif.**—The artificial formation of some of the micas has been recently accomplished by several methods. Early statements on the occurrence of mica-like minerals in slags are more or less questionable; more recently Vogt (Ak. H. Stockh., Bih. **9**, 1, 39, 1884) describes mica in the slags of Kafveltorp, see also Id., Arch. Math. Nat., **13**, 90, 1889. Hautefeuille and St. Giles (C. R., **104**, 508, 1887) by fusing the constituents of iron-mica mixed with $\frac{1}{5}$ of fluoride of silicon and potassium obtained on cooling (when some 3 to 4 p. c. of fluorine still remained) a mass of thin hexagonal tables, which were uniaxial, highly pleochroic (pale and deep brown). Similar mica scales of colorless, green, or brown were obtained when a small amount of potassium arsenate was added, and hydrogen allowed to act on the fused mass. Khrushchov in 1888 (Bull. Soc. Min., **11**, 173) announced the formation of biotite, margarite, and muscovite(?) by fusing together different substances (as magnesia, baryta, cryolite) with lepidolite or a magma having its composition with an excess of silica, alumina and alkaline fluorides. Cf. also Min. Mitth , **9**, 55, 1887, in which place the same author earlier describes an artificial magnesium mica. Doelter (Min. Mitth., **10**, 67, 1888, Jb. Min., **2**, 178, 1888) has also found several of the micas by fusing various natural silicates (hornblende, actinolite, glaucophane, andalusite, garnet, etc.) with the fluorides of sodium and magnesium; micas corresponding to biotite, phlogopite, muscovite, zinnwaldite were obtained.

Pliny probably included the mineral mica with the *Lapis specularis* (**36**, 45) or *Selenite;* and the shavings or scales of *Lapis specularis* strown over the "Circus Maximus," to produce an agreeable whiteness, were probably those of a soft silvery mica schist. His *Hammochrysos* also (**37**, 73, named from *ἄμμος, sand, χρυσός, gold)* was probably sand from a yellowish mica schist, which abounds by the roadside in many mica-schist regions. Agricola speaks of the deceptive character of this silvery and golden dust, as cited below. This silvery and golden mica in scales is the *Cat-silver* and *Cat-gold* of mediæval Europe (Katzengold, Katzensilber, *Germ.*, Or (Argent) des chats *Fr.*).

The following is the synonymy of the mineral since the time of Pliny:

Mica, Ammochrysos, colore argento ita simile sit, ut pueros et rerum metallicarum imperitos decipere possit, *Germ.* Glimmer, Katzen-Silber, *Agric.*, Foss., 254, 447, Interpr., 466, 1546. Specularis lapis adulterinus flexilis sexangulorum *Capeller*. Prodr. Cryst., 26, 1723. Mica [Talc not included]. Vitrum Muscoviticum. V. Rutheniticum, Skimmer, VAR. alba (Kattsilver), flava (Kattgull), rubra, viridis [Chlorite fr. Sahlberg] nigra. squamosa. radians, fluctuans, hemispherica, *Wall.*, Min., 129, 131, 1747. Mica pt. [rest Talc, Chlorite], Verre de Moscovie, etc., *Fr. Trl.* Wall., **1**, 241, 1753. Mica, Glimmer, Vitrum Muscoviticum (in plates), Mica squamosa (in scales) *Cronst.*, Min., 88, 1758. Isinglass (in large plates), Glimmer or Mica (in small scales) pt. (rest Talc, Chlorite) *Hill*, Foss., 10, 13, 1771. Glimmer [Chlorite and Talc excluded] *Wern.*, Bergm. J., 37, 1789.

The word *mica* has been said to come from the Latin *mica, a crumb* or grain, as it was formerly applied especially to the mineral in scales. It is usually derived, however, from the Latin *micare*, signifying (like the German name *Glimmer*) *to shine.*

**Ref.**—[1] On the crystallization of the micas, see Tschermak, who first proved them to be all monoclinic, Ber. Ak. Wien, **76** (1), 97, 1877, and Zs. Kr., **2**, 14, 1877; also Koksharov, Mem. Ac. St. Pet., **24**, 1, 1877, Min. Russl., **7**, 167, *et seq.*, **8**, 1, etc.; cf. also references under the individual species beyond. [2] Reusch ("Körnerprobe"), Ber. Ak. Berlin, 428, July 9, 1868, 83, Feb. 4, 1869, 440, May 29, 1873. [3] Bauer, percussion- and pressure-figures, Pogg., **138**, 337, 1869; Zs G. Ges., **26**, 137, 1874. See also Reusch, Ber. Ak. Berlin, 530, 1869, on the effect of superimposed mica plates with axes inclined 60° in producing elliptically polarized light; also Cooke, Mem. Am. Ac. Boston, 35, 1874. *Etching-figures*, Baumhauer, Zs. Kr., **3**, 113, 1878; Wiik, Öfv. Finsk. Soc., 22, 1880. *Elasticity* investigated, Coromilas, Inaug. Diss., Tübingen, 1877 (Zs. Also *ρ* ($\bar{2}$05, $\tfrac{2}{5}$-ī), *ζ* (135, − $\tfrac{3}{5}$-3̀), gliding-planes.

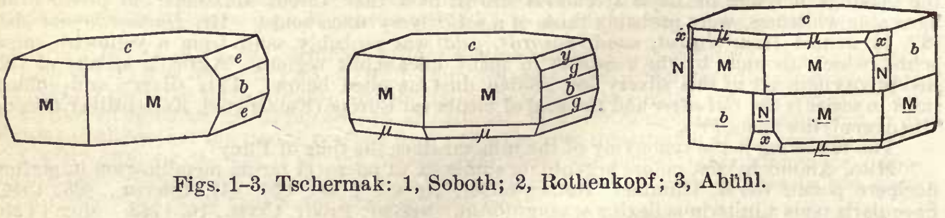

Figs. 1–3, Tschermak: 1, Soboth; 2, Rothenkopf; 3, Abühl.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| *cρ* | = 66° 32′ | *cn* | = 78° 32½′ | *cζ* | = 66° 25′ | *NN′* | = 119° 48′ |
| *ce* | = 65° 38′ | *cM* | = *85° 36′ | *oo′* | = 57° 10′ | *ζζ′* | = 105° 4′ |
| *cr* | = 73° 12′ | *cμ* | = *81° 30′ | *MM′* | = 59° 48′ | *bx* | = 30° 22′ |
| *cy* | = 77° 15′ | *cx* | = 85° 4′ | *μμ′* | = 59° 16½′ | *bN* | = 30° 6′ |
| *co* | = 73° 7½′ | *cN* | = 87° 27½′ | *xx′* | = 119° 16′ | *bcM* | = *60° 0′ |

Twins common according to the *mica-law:* tw. plane a plane in the zone *cM* normal to *c*, the crystals often united by *c* and chiefly left-handed twins (see further under biotite, and f. 3, 4, p. 628). Crystals rhombic or hexagonal in outline with plane angles of 60° or 120°. Habit tabular, passing into tapering forms with planes more or less rough and strongly striated horizontally; vicinal forms common. Folia often very small and aggregated in stellate, plumose, or globular forms; or in scales, and scaly massive; also crypto-crystalline and compact massive.

Cleavage: basal, eminent. Also planes of secondary cleavage ‖ *b* and several undetermined pyramids in the unit series as shown in the percussion-figure, which is a six-rayed star with rays ‖ *m*, *m′* and *b*, see p. 611. Parting by pressure further developed ‖ the gliding-planes $\rho$ $(\bar{2}05)$ and $\zeta$ (135) inclined about 66½° to *c*; natural plates hence often yield narrow strips or thin fibers ‖ axis *b*, and less distinct in directions inclined 60° to this; the traces of these planes of parting on *c* give the pressure-figure (p. 612). Thin laminæ flexible and elastic when bent, very tough, harsh to the touch, passing into kinds which are less elastic and have a more or less unctuous or talc-like feel. Etching-figures on *c* monoclinic in symmetry.

H. = 2–2·5. G. = 2·76–3. Luster vitreous to more or less pearly or silky. Colorless, gray, brown, hair-brown, pale green, and violet, yellow, dark olive-green, rarely rose-red. Streak uncolored. Transparent to translucent.

Pleochroism usually feeble; distinct in some deep colored varieties (see beyond). Absorption in the direction normal to the cleavage plane (vibrations ‖ $\mathfrak{b}$, $\mathfrak{c}$) strong, much more so than transversely (vibrations ‖ $\mathfrak{a}$); hence a crystal unless thin is nearly or quite opaque in the first direction when translucent through the prism. Optically −. Double refraction rather strong. Ax. pl. ⊥ *b* and nearly ⊥ *c*. $Bx_a$ (= $\mathfrak{a}$) inclined about − 1° (behind) to a normal to *c*. Dispersion $\rho > v$. Axial angle variable, usually about 70°, but diminishing to 50° in kinds (phengite) relatively high in silica. The axial angle also diminishes somewhat with increase of temperature. Axial angles, Tschermak:

| | | | | |
|---|---|---|---|---|
| Bengal | $2E_r = 69° 12'$ | $2E_y = 68° 54'$ | $2E_{gr} = 68° 30'$ | $2E_{bl} = 67° 54'$ |
| Abühl | $2E_r = 63° 1'$ | $2E_y = 62° 46'$ | $2E_{gr} = 62° 15'$ | |
| Rothenkopf | $2E_r = 60° 38'$ | $2E_y = 60° 12'$ | $2E_{gr} = 60° 6'$ | |

Also, Scharizer:

| | | | | |
|---|---|---|---|---|
| Schüttenhofen | $2E_r = 74° 50'$ | $2E_y = 73° 52'$ | $\beta = 1·5135$ | $\gamma = 1·5261$ |
| | $2E_r = 70° 40'$ | $2E_y = 70° 4'$ | | |

A large number of measurements of the axial angle are given by Silliman, also others by Grailich these are quoted in 5th Ed., pp. 312–314.

Refractive indices:

| | | | |
|---|---|---|---|
| $\alpha_y = 1·5609$ Na | $\beta_y = 1·5941$ | $\gamma_y = 1·5997$ | Kohlrausch |
| $\alpha_r = 1·5566$ Li | $\beta_r = 1·5899$ | $\gamma_r = 1·5943$ | Pulfrich |
| $\alpha_y = 1·5601$ Na | $\beta_y = 1·5936$ | $\gamma_y = 1·5977$ | " |
| $\alpha_{gr} = 1·5635$ Tl | $\beta_{gr} = 1·5967$ | $\gamma_{gr} = 1·6005$ | " |

Measurements showing variation of axial angle with temperature, Dx.:

| | | | | |
|---|---|---|---|---|
| N. Hampshire | $2E_r = 70° 29'$ at 12° | 68° 56′ at 95°·5 | 68° 17′ at 146°·5 | 68° 5′ at 185°·8 |
| Goshen, *rose-red* | $2E = 76° 35'$ at 12° | 76° 7′ at 95°·5 | 75° 30′ at 146°·5 | 75° 10′ at 170°·8 |

Tschermak found the apparent angle between $Bx_a$ (= $\mathfrak{a}$) and the normal to *c* for crystals from Abühl, − 1° 42′; Bengal, − 1° 40′; East Indies, − 0° 31′.

**Var.**—1. *Ordinary Muscovite.* In crystals as above described, often tabular ‖ *c*, also tapering with vertical faces rough and striated; the basal plane often rough unless as developed by cleavage. More commonly in plates without distinct outline, except as developed by pressure (see above); the plates sometimes very large, but passing into fine scales, arranged in plumose or other forms. In normal muscovite the thin laminæ spring back with force when bent, the scales are more or less harsh to the touch, unless very small, and a pearly luster is seldom prominent.

2. DAMOURITE. Including margarodite, gilbertite, hydro-muscovite, and most hydro-mica in general. Folia less elastic and luster somewhat pearly or silky and feel unctuous like talc. The scales are usually small and it passes into forms which are fine scaly or fibrous, as sericite, and finally into the compact crypto-crystalline kinds called oncosine, including much pinite.

Axial angle for damourite chiefly from 60° to 70°; for Pontivy 10°–12° Dx. Named after the French chemist, Damour. Often derived by alteration of cyanite, topaz (anal. 21, 22), corundum (anal. 27). Although often spoken of as *hydrous* micas, it does not appear that damourite and the varieties following necessarily contain more water than ordinary muscovite; they may, however, give it off more readily.

*Sterlingite*, Cooke, is a variety of damourite from Sterling, Mass., associated with spodumene in the vein of a large boulder rock. It differs from the damourite of Pontivy only in having a large axial angle (70°), which, however, has proved to be characteristic of most damourite.

*Margarodite*, as named by Schafhäutl, was the talc-like mica of Mt. Greiner in the Zillerthal (anal. 36); granular to scaly in structure, luster pearly, color grayish white. By various authors (Greg & Lettsom, Kenngott, Dana, 5th Ed., *et al.*) the name has been used for kinds of muscovites now more commonly embraced under the head of damourite. Named from μαργαρίτης, a *pearl*, in allusion to the luster.

Tschermak notes that the original margarodite has something of the brittleness of paragonite and margarite; he regards it as a mixture of these micas with muscovite.

*Gilbertite*, as originally described by Thomson, was in whitish, silky forms from the tin mine of Stenna-Gwynn (Stonagwyn), St. Austell, Cornwall, with fluorite in granite. Named after Davies Gilbert, a President of the Royal Society. Frenzel describes the same mineral from the tin mines of the Erzgebirge (Saxony and Bohemia), Ehrenfriedersdorf, Zinnwald, etc.

It has a greenish to yellowish white color; translucent. H. = 1. G. = 2·65–2·72. It occurs massive, with a dense to crystalline structure, filling cavities between the cassiterite and wolframite. A second variety occurs in spherical or stellate forms, and also in groups of six-sided tabular crystals. It is, moreover, found pseudomorph after scheelite and apatite. H. = 3. G. = 2·82. Greg & Lettsom (p. 201) include gilbertite and also Thomson's nacrite and talcite under margarodite.

Talcite is from Wicklow, Ireland, where it invests crystals of andalusite; called by Thomson crystals of nacrite.

*Adamsite* of Shepard is a greenish black mica, constituting a micaceous schist or rock in Derby, Vt. It contains, according to G. J. Brush (Am. J. Sc., **34**, 216, 1862): $SiO_2$ 47·76, $Al_2O_3(Fe_2O_3)$ 36·29, CaO 0·24, MgO 1·85, alkalies [8·77], ign. 5·09 = 100. It has all the ordinary characters of common mica; it is referred by Brush to margarodite.

*Ivigtite T. D. Rand*, Proc. Ac. Philad., 142, 1868. In films and seams in massive cryolite from Greenland. Granular, approaching micaceous. H. = 2–2·5. G. = 2·05. Color pale yellowish green to yellow. Analysis: $SiO_2$ 36·49, $Al_2O_3$ 24·09, $Fe_2O_3$ 7·54, $Na_2O$ 16·03, F 0·75, $H_2O$ 3·42, loss 11·68 = 100. See Hagemann, Am. J. Sc., **47**, 133, 1869, and Min., App. I, p. 7; also Johnstrup, who refers it to gilbertite, Förh. Skand. Nat., **12**, 240, 1883.

*Sericite* is a fine scaly muscovite united in fibrous aggregates and characterized by its silky luster (hence the name from σηρικός, *silky*). It was described from the silky-schist (sericite-schist) of the Nerothal near Wiesbaden, and shown to have a somewhat wide distribution in the Taunus and elsewhere. Its essential identity with muscovite, earlier suggested, has been insisted upon by Laspeyres (Zs. Kr., **4**, 244, 1879), and later by others. It is shown that the material analyzed has usually been more or less impure. According to Laspeyres the original sericite was derived from the alteration of feldspar.

*Metasericite* of Sandberger is a greenish white fine scaly substance with a soapy feel. It occurs as an alteration-product of oligoclase in granular gneiss of the Wildschapbach-Thal in Baden. See anal. 45.

*Lepidomorphite*, also of Sandberger, is a fine scaly product of the alteration of oligoclase in the granite of Wittichen, Baden. It has the high silica of the phengite varieties of muscovite; anal. 46.

*Pycnophyllite* forms spherical or elongated masses with quartz in mica schist. Feel greasy, talc-like. Color leek-green, apple-green, sea-green. From Kohlgraben (anal. 47), also from Aspang, in the Klein-Pischingbach-thal in Austria (anal. 48).

*Leucophyllite* forms masses resembling sericite from the Anna-Kapelle, northwest of Wiesmath (anal. 49), and from Ofenbach near Frohsdorf on the Leitha, Austria (anal. 50).

3. Oncosine. Forms rounded aggregates, compact in structure and of a light green color, embedded in dolomite of Passecken near Tamsweg, Salzburg. It has been referred to pinite and is probably to be taken as a compact form of muscovite (cf. Tschermak).

Named from ογκωσις, a *swelling up*, in allusion to its intumescence B.B. A compact form of muscovite from South Africa has been described by Cohen, Jb. Min., **1**, 123, 1887, and anal. 51, 52. See further p. 621 for other substances referred to pinite, which, so far as they are homogeneous, probably belong here with muscovite.

*Oncophyllite* is a name proposed by Sandberger for the secondary compact mica, like oncosine, derived from the alteration of feldspar.

*Didymite* (didrimite, amphilogite) is mica in fine scales of a greenish or grayish white color, occurring in the chlorite schists of the Zillerthal, and supposed to be peculiar in containing calcium carbonate; this, however, is probably due to impurity. Named didymite from δίδυμος, *twin;* amphilogite from αμφίλογος, *doubt*, in allusion to the uncertain composition.

The following are peculiar in composition:

Fuchsite. Chromglimmer *Germ.* A mica characterized by the presence of chromium sesquioxide. The original was from Schwarzenstein in the Zillerthal (anal. 53); other varieties have since been noted from other points. Named from the chemist, J. N. v. Fuchs.

A chromium mica from the Ural, examined by Arzruni (anal. 56), gave the axial angles: $2E_r = 71° 34'$. $2E_y = 68° 35'$, $2E_{gr} = 67° 17'$.

Another from Montgomery Co., Maryland, examined by A. C. Gill (anal. 58), was strongly pleochroic: 𝔠 bluish chrome-green; 𝔟 yellowish green; 𝔞 robin's-egg blue. Axial angles: $2E_r = 71° 24'$ Li, $2E_y = 68° 16'$ Na.

The variety from Ouro Preto, analyzed by Gorceix (anal. 60) gave Des Cloizeaux 2E = 69° to 70°, dispersion $\rho > v$.

AVALITE *Losanitsch*, Ber. Chem. Ges., **17**, 1774, 1884. Occurs in earthy aggregates of thin crystalline scales in the quartzyte of Mt. Avala near Belgrade. Analysis of material freed by decantation and boiling in aqua regia from impurities, except some sand and chromite:

| $SiO_2$ | $Cr_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | $K_2O$ | ign. | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 56·13 | 14·59 | 14·37 | 1·10 | 0·43 | 3·54 | 5·38 | 2·39 chromite 1·68 = 99·61 |

Two other analyses of less pure material gave about the same results. It apparently belongs near the above chromium micas, but the material examined was too impure to allow of a decision in regard to its exact composition.

OELLACHERITE including part of the so-called barium mica (other kinds belong to biotite), contains several per cent. of BaO. G. = 2·884–2·994. $2E_r = 79° 21'$, $2E_{bl} = 78° 45'$, Dx. The original occurs near Kemmat in the Pfitschthal, Tyrol. Occurs also in the mica schist of the Habachthal, Salzburg, Sandberger, Jb. Min., 624, 1875, 367, 1879. See anals. 61–63.

**Comp., Var.**—For the most part an orthosilicate of aluminium and potassium $(H,K)AlSiO_4$. If, as in the common kinds, H : K = 2 : 1, this becomes $H_2KAl_3Si_3O_{12} = 2H_2O.K_2O.3Al_2O_3.6SiO_2$ = Silica 45·2, alumina 38·5, potash 11·8, water 4·5 = 100.

Some kinds give a larger amount of silica than corresponds to a normal orthosilicate, and they are called *phengite* by Tschermak (cf. p. 612), anal. 16 *et seq.* This name was given originally by Breithaupt. As shown by Clarke, these acid muscovites (cf. p. 613) can be most simply regarded as molecular mixtures of $H_2KAl_3(SiO_4)_3$ and $H_2KAl_3(Si_3O_8)_3$.

Iron is usually present in small amount only; barium is rarely present as above noted, also chromium in some cases.

[a] Incl. 0·29 p. c. MnO.

The rose-colored mica, of Goshen, Mass. (erroneously called lepidolite), afforded Mallet: $K_2O$ 9·08, $Na_2O$ 0·99, $Li_2O$ 0·64, Am. J. Sc., **23**, 180, 1857. Cf. also anal. 8.

**Pyr., etc.**—In the closed tube gives water, which with brazil-wood often reacts for fluorine. B.B. whitens and fuses on the thin edges (F. = 5·7, v. Kobell) to a gray or yellow glass. With fluxes gives reactions for iron and sometimes manganese, rarely chromium. Not decomposed by acids. Decomposed on fusion with alkaline carbonates.

**Obs.**—Muscovite is the most common of the micas. It is one of the essential constituents of granite, gneiss, mica schist, and other related rocks, and is occasionally met with in granular limestone; in volcanic rocks it is rare; it occurs also disseminated sparingly in many fragmental rocks. The crystallized forms are most common in cavities in granite, associated with adularia, albite, tourmaline, etc. Coarse lamellar aggregations often form the matrix of topaz, tourmaline, and other mineral species in granitic veins. The varieties with unctuous talc-like feel and pearly or silky luster are characteristic of much mica (" hydro-mica ") schist which has often been erroneously called talcose schist. Muscovite is frequently of secondary origin, being derived from the alteration of other species, *e.g.*, topaz, cyanite (damourite), feldspar (oncosine), etc., cf. also pinite, beyond; muscovite forms with albite the mineral-aggregate called cymatolite, derived from spodumene, cf. p. 368.

Muscovite often encloses flattened crystals of garnet, tourmaline, also quartz in thin plates between the sheets; further not infrequently magnetite in dendrite-like forms following in part the directions of the percussion-figure, also those of the pressure-figure (f. 1, p. 611). These markings were erroneously referred by Rose to hematite; their true nature was shown by Brush (Am. J. Sc., **48**, 361, 1869). Rose's argument against their being magnetite, based upon their want of opacity, has no force, since even the native metals are translucent in sufficiently thin layers.

Many localities of muscovite, and of the different varieties, have been given in the preceding pages. Some of the best known localities, more especially those which have furnished well crystallized specimens, are: Abühl in the Sulzbachthal, with adularia; similar on the Rothenkopf in the Zillerthal, Tyrol; Soboth, west of Eibiswald in Styria, also St. Radegrund; St. Gothard, Binnenthal, and elsewhere in Switzerland; Mourne Mts., Ireland; Cornwall; Utö, Finbo, Falun, Sweden; Skutterud, Norway. In the region of Ekaterinburg, at Alabashka near Mursinka, in cavities in granite and at other points in the Ural, sometimes in large plates; also in the Ilmen Mts. on the east side of L. Ilmen; San Domingo, Brazil. Also obtained in large plates from Greenland.

Exported in large quantities from the East Indies and most of it from the Hazáribágh district in Bengal; also obtained in large plates in the granite veins of Mysore, and at Wangtu bridge on the Sutlej in the Punjab Himalayas (Mallet, Min. India, 97, 1887).

In *Maine*, at Mount Mica in the town of Paris; at Buckfield, in fine crystals; also at East Woodstock; Rumford; at Unity, of a green color, on the estate of James Neal (Thomson's *nacrite*, wrongly referred to Brunswick). In *N. Hamp.*, at Acworth, Grafton and Alstead, in granite, the plates at times a yard across and perfectly transparent; also in Groton (Valencia mine); at Nashua; Hoyt hill in Orange. In *Mass.*, at Chesterfield, with tourmaline and albite, sometimes pink; at Barre and South Royalston, in two localities, with beryl; at Mendon and

Brimfield; at Chester, Hampden Co., faint greenish; at Goshen, rose-red (anal. 8, sometimes misnamed lepidolite); prismatic mica, at Russell. In *Conn.*, at Monroe, of a dusky brown color, having internal hexagonal bands of a darker shade; at Glastonbury, with feldspar; at Trumbull, at the topaz vein in coarse radiated aggregations; at Litchfield, with cyanite, colorless and pearly; in brown hexagonal crystal at the Middletown feldspar quarry; at Haddam, pale brownish, with columbite, and also similar at another locality with garnets; at Branchville, with albite, microcline, spodumene, etc., both in large sheets and in aggregates with curved concentric structure; New Milford, with feldspar, green and yellow beryl, etc.

In *N. York*, 6 m. S.E. of Warwick, crystals and plates sometimes a foot in diameter, in a vein of feldspar; a mile N.W. of Edenville, in six-sided and rhombic prisms; silvery, near Edenville; in St. Lawrence Co., 8 m. from Potsdam, on the road to Pierrepont, in plates 7 in. across; town of Edwards, in large prisms, six-sided or rhombic; Greenfield, near Saratoga, in reddish brown crystals with chrysoberyl; on the Croton aqueduct, near Yonkers, in rhombic prisms with a transverse parting.

In *Penn.*, in fine hexagonal crystals of a dark brown color at Pennsbury, near Pennsville, Chester Co.; at Unionville, whitish; Delaware Co., at Middletown, smoky brown with hexagonal internal bands, which are due to magnetite; at Chesnut Hill, near the Wissahickon, a green variety; at Leiperville, Delaware Co., faint greenish. In *N. Jersey*, in crystals at Newton and Franklin. In *Maryland*, at Jones's Falls, a mile and three-quarters from Baltimore; the plates show by transmitted light a series of concentric hexagons, the sides of which are parallel with the sides of a hexagonal prism; it has been mined in Howard and Montgomery Cos. In *Virginia*, at Amelia Court House, with albite, microlite, beryl, monazite, helvite; also in Grayson, Henry, Patrick, Carroll Cos. In *No. Carolina*, extensively mined at many places in the western part of the state, and often obtained in very large sheets, at times more than 3 feet in diameter; there are numerous localities in Macon, Jackson, Haywood, Buncombe, Ashe, McDowell, Mitchell, Yancey, Alexander, Cleveland, and other counties; the chief mines are in Mitchell, Yancey, Jackson, and Macon Cos. The mica mines have also afforded many rare species, as columbite, samarskite, hatchettolite, uraninite, etc. A pink-colored muscovite occurs at Ray's mine in Yancey Co., and at the Flat Rock mine, Mitchell Co. Occurs in fine crystals at the spodumene (hiddenite) locality in Alexander Co., the crystals often dusted over with a chloritic coating giving them a bronze appearance; with magnetite at Buckhorn, Chatham Co.; with quartz at Hickory, Catawba Co.; with pyrite in Stokes Co. Compact to fibrous or scaly varieties occur at various points with corundum in Macon Co., and elsewhere; also a kind in yellow or white pearly scales as a result of the alteration of cyanite at Crowder's and Clubbs' mountains; similarly in Yancey Co., and other points. Soft pseudomorphous crystals having the form of staurolite, from Cherokee Co., are referred to muscovite by Genth. In *S. Carolina*, muscovite deposits occur in Anderson, Oconee, and Pickens Cos.; also in Georgia and Alabama.

Mica mines have also been worked to some extent in the Black Hills, in Custer and Pennington Cos. of South Dakota; in Washington, at Rockford, Spokane Co.; in Colorado, at Turkey Creek, 35 miles from Denver; near Pueblo; also from the neighborhood of Fort Collins. In New Mexico, at the Cribbensville mines, Petaca, Rio Arriba Co. In California, at Salmon Mt., Siskiyou Co.; deposits also occur at Gold Lake, Plumas Co.; El Dorado Co.; Ivanpah distr., San Bernardino Co.; Susanville, Lassen Co.; Kern Co. It is a common mineral at many points in the granite of the western United States.

The production of mica in the United States was 70,500 pounds in 1887, valued at $142,250; 2000 tons of mica waste were ground worth $15,000. The amount mined in 1888 was much smaller, while in 1882, 1883, 1884, the amount varied from 100,000 pounds to 147,410 pounds (Min. Res. U. S.).

Muscovite was so named by J. D. Dana in 1850, from *Vitrum Muscoviticum* or *Muscovy-glass*, formerly a popular name of the mineral. The derivations of the names of prominent varieties are given in the preceding pages.

**Alt.**—Mica at times becomes hydrated, losing its elasticity and transparency, and often some portion of the potash; and at the same time it may take up magnesia, lime, or soda. These changes may be promoted by waters containing carbonates of these bases. It occurs altered to *steatite* and *serpentine*, and cases of alteration to amphibole and stilpnosiderite have been mentioned. It sometimes passes by alteration into a form of "vermiculite." Cf. p. 664. A mica from Leon Co., Texas, has been examined by G. W. Leighton, which is characterized (J. P. Cooke) as an early stage in this alteration. Opaque; laminæ brittle; luster pearly; B.B. swells, the laminæ separate and fuses at 5 to 6. Analysis, Leighton, Am. J. Sc., **32**, 317, 1886:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 48·95 | 25·17 | 9·40 | 1·69 | *tr.* | 11·08 | *tr.* | 4·31 | = 100·60 |

**Artif.**—See p. 613.

**Ref.**—[1] Rothenkopf, Zillerthal, l. c. (ref. 614). For crystals from Abühl Tschermak calculates $001 \wedge 201 = 84° 9'$. Cf. also Marignac, Bibl. Univ., **6**, 300, 1847; Dx., Min., **1**, 485, 1862; Kk., Min. Russl., **2**, 121 *et seq.*, **7**, 225 *et seq.* (Mem. Akad. St. Pet., 1877, read May 17), **8**, 5, 1878. See also Kk., ibid., **7**, 301–344, for valuable abstracts of early papers, literature, etc. On vicinal planes on the muscovite of Abühl, Rothenkopf, see Tschermak, l. c.

The position here taken is that finally adopted by Tschermak (priv. contr., May, 1891) as most satisfactorily showing the relation to the other micas, the chlorites, etc. Tschermak (l. c., 1877, and Min., 1883) earlier made $M = 110$, $e = 011$, $\rho = \bar{1}02$, $\zeta = 133$, etc.; for this the fundamental angles on p. 614 give the axial ratio:

$$\grave{a} : \breve{b} : \acute{c} = 0{\cdot}5775 : 1 : 2{\cdot}2175 \qquad \beta = 84° \, 55'.$$

This position has certain obvious advantages in simplicity of symbols, etc., to the one adopted. Cf. also p. 614. Muscovite was earlier regarded as orthorhombic with monoclinic hemihedrism.

On *percussion-figure*, pressure-figure, etc., see references on p. 614. *Etching-figures* Baumhauer, Ber. Ak. München, 245, 1874, 99, 1875; Wiik, Zs. Kr., **7**, 187 (ref.), 1882. *Elasticity*, Coromilas, Inaug. Diss., Tübingen, 1877, abstr. in Zs. Kr., **1**, 411, 1877.

*Refractive indices*, see Bauer, Ber. Ak. Berlin, p. 693, Nov. 27, 1877; Min. Mitth., **1**, 14, 1878; Kohlrausch [Vh. Ges. Würzburg, **12**, 1877]; Matthiessen, Zs. Sc., **10**, 372, 1850; Grailich, Ber. Ak. Wien, **11**, 46, 1853; Bauer, Pogg., **138**, 350, 1869 *et al.;* Dx., l. c., and N. R., 75–81, 1867. *Electrical conductivity*, inductive power, etc., J. Curie, Ann. Ch. Phys., **17**, 385, 1889, **18**, 229, 1889; Schultze, Wied. Ann., **36**, 655, 1889; Bouty, C. R., 110, 846, 1890.

**Pinite.** A general term used to include a large number of alteration-products of iolite, spodumene, nephelite, scapolite, feldspar, and other minerals. In composition essentially a hydrous silicate of aluminium and potassium corresponding more or less closely to muscovite, of which it is probably to be regarded as a massive, compact variety, usually very impure from the admixture of clay and other substances.

Characters, as follows: Amorphous; granular to cryptocrystalline. Rarely a submicaceous cleavage. H. = 2·5–3·5. G. = 2·6–2·85. Luster feeble, waxy. Color grayish white, grayish green, pea-green, dull green, brownish, reddish. Translucent to opaque.

The following are some of the minerals classed as pinite (cf. also p. 616). They are further referred to under the original minerals in the several cases; typical analyses are given below; for others, see 5th Ed., pp. 481, 482.

PINITE. Speckstein [fr. the Pini mine at Aue, near Schneeberg] *Hoffmann*, Bergm. J., 156, 1789; Kieselerde + Thonerde, etc., *Klapr.*, ib., 227, 1790. Pinit *Karsten*, Tab., 28, 73, 1800. The original pinite is in 6- to 12-sided prisms; color brown; occurs in granite, pseudomorphous after iolite.

GIGANTOLITE *Nordenskiöld*, Act. Soc. Sc. Fenn., **1**, 2, 377, 1840. From gneissoid granite of Tammela, Finland, in large 6- and 12-sided prisms, with basal cleavage; H. = 2·5; G. = 2·862–2·878; luster somewhat waxy; color greenish to dark steel-gray, sometimes approaching submetallic in luster, owing to the alteration of the original iolite and the presence of uncombined oxide of iron. *Iberite* Svanberg (Öfv. Ak. Stockh., **1**, 219, 1844), from Montalvan, near Toledo, Spain, is the same mineral in characters; H. = 2·5; G. = 2·89. Both are a result of the alteration of iolite.

GIESECKITE (fr. Greenland, *Allan*, Ann. Phil., **2**, 1813). In 6-sided prisms, pseudomorphous after nephelite. Brought by Giesecke from Akulliardsuk and Kangerdluarsuk, Greenland, where it occurs in compact feldspar. Also from Diana, N. Y. See *nephelite*, p. 426.

LYTHRODES *Karsten*, Mag. Ges. Fr. Berlin, **4**, 78, 1810; *John*, Ch. Unt., **1**, 171; Splittriger Wernerit *Hausm.*, 520, 1813, is from the zircon-syenite of Fredriksvärn and Laurvik. It is regarded as altered nephelite.

LIEBENERITE *Marignac*, Bibl. Univ., **6**, 193, 1848, is essentially the same; from a porphyritic feldspathic rock of Mt. Viesena, in the Fleimsthal; it occurs in 6-sided prisms.

DYSYNTRIBITE *Shepard*, Proc. Am. Assoc., 311, 1851, Am. J. Sc., **12**, 209, 1851. Essentially the same with the gieseckite from Diana and elsewhere, Lewis Co., N. Y.; it constitutes masses or a rock, sometimes slaty in structure, and somewhat resembles serpentine, though more waxy in aspect; H. = 3–3·5; G. = 2·76–2·81; colors often mottled, usually greenish, sometimes reddish or spotted with red. Associated with phlogopite, etc.

PAROPHITE *T. S. Hunt*, Rep. G. Can., 1852, 1863. Similar to dysyntribite, but less pure, it is regarded by Hunt as a rock, and not a simple mineral; the name alludes to a resemblance to serpentine. It constitutes a schistose rock at St. Nicholas and Famine R., Can.; also in Stanstead, on the E. shore of L. Memphremagog, with chloritic schist; and at Pownal, Vermont.

ROSITE *Svanberg* (Ak. H. Stockh., 1840). A granular red mineral, occurring in granular limestone at Åker in Södermanland; H. = 2·5, G. = 2·72. G. Rose and others make it *altered anorthite.*

POLYARGITE *Svanberg*, l. c. Occurs in reddish lamellar masses at Tunaberg, Sweden; H. = 4; G. = 2·768; named from πολύς, *much*, and ἀργός, *sparkle.* Cf. Palmgren, G. För. Förh., **1**, 188, 1873. The name *Pyrrholite* has been given to a reddish lamellar mineral from Tunaberg, which is very similar to polyargite (Dx., Min., **1**, 302, 1862); it has H. = 3–4; and cleavage surfaces inclined together about 87°; and is apparently anorthite less altered than in rosite and polyargite.

PINITOID *A. Knop* (Jb. Min., 558, 1859). A rock, like dysyntribite in characters, and a schist called "*pinitoid schist*" approaches parophite. *Pinitoid* has H. = 2·5; G. = 2·788; color leek-, oil-, and grayish green. Occurs in the region between Freiberg and Chemnitz, Saxony, pseudomorphous after feldspar, in a half-decomposed granitic porphyry, constituting about 25 p. c. of the rock. Also from other localities, cf. Cohen, Zs. Kr., **7**, 405, 1882.

HYGROPHILITE *Laspeyres*, Min. Mitth., 147, 1873. A pinite-like substance, at least in part derived from feldspar. G. = 2·670. From Halle-an-der-Saale. A similar mineral occurs as the result of the alteration of oligoclase in the gneiss of the Wildschapbach-Thal, Baden (Sandberger, Unt. Erz., 59, 1882.

WILSONITE *T. S. Hunt*, Rep. G. Can., 1853, 1863. A pseudomorph, with the form and cleavage of *scapolite;* H. = 3 5; G. = 2·76–2·78; luster somewhat pearly; color rose-red; fragments translucent. It is from Bathurst. Can , where it was first found by Dr. Wilson; also St. Lawrence Co., N. Y. See also p. 473. *Terenite* (p. 473), from Antwerp, St. Lawrence Co., may be the same.

KILLINITE *Thomson*, Min., **1**, 330, 1836. From Killiney Bay, Ireland, pseudomorph after spodumene, see p. 368.

Grattarola describes a pinite formed from andalusite from San Piero, Elba, Boll. Com. Geol., 333, 1876.

The pinite of Stolpen near Neustadt, called *micarel* by Freiesleben (p. 473), is according to Wichmann not a pseudomorph after iolite, Zs. G. Ges., **26**, 701, 1874.

AGALMATOLITE (Agalmatolithus. Bildstein (fr. China), *Klapr.*, Beitr., **2**, 184, 1797. Pagodite *Napione*. J. Phys., **46**, 220, 1798). Like ordinary massive pinite in its amorphous compact texture, luster, and other physical characters, but contains more silica, which may be from free quartz or feldspar as impurity. The Chinese has H. = 2–2·5; G. = 2·785–2·815, Klapr. Colors same as for pinite, usually grayish, grayish green, brownish, yellowish.

A similar mineral in composition comes from Nagyág in Transylvania, and Ochsenkopf near Schwarzenberg in Saxony. *Agalmatolite* was named from *ἄγαλμα, an image*, and *pagodite* from *pagoda*, the Chinese carving the soft stone into miniature pagodas, images etc. Part of the so-called agalmatolite of China is true pinite in composition, another part is compact pyrophyllite, and still another steatite (see these species).

OOSITE (Oösit *Marx*, ib., **3**, 216, 1834), is near oncosine (p. 616); it is white to reddish or brownish red, and occurs in 6- and 12-sided prisms; it is from the Oös valley, Baden, occurring in what is called pinite-porphyry.

*Gongylite* (Gongylit *Thoreld*, Act. Soc. Sc. Fenn., **3**, 815, A. Nord., Beskrifn. Finl. Min., 146, 1855) is yellowish or yellowish brown, and has cleavage in two directions; with H. = 4–5; G. = 2·7. From a schist called talcose schist at Kimsamo in Finland.

**Anal.**—1, Rg., Min. Ch. 835, 1860. 2, Hauer, Jb. G. Reichs., **5**, 76, 1854. 3, Brush, Am. J. Sc., **26**, 641, 858. 4, Hauer, l. c., 147, 1853. 5, Smith and Brush, Am. J. [a] MnO.

The pinite of anal. **9** is described by Crosby (l. c., also Am. J. Sc., **19**, 116, 1880) as common in eastern Massachusetts, especially in the vicinity of Boston, where it occurs as a soft, greenish, unctuous mineral, both in the felsyte and the conglomerate. In the latter it makes up much of the pebbles and the enclosing paste, and is referred for its feldspathic origin to Primordial times.

CATASPILITE. Kataspilit *Igelström*, Öfv. Ak. Stockh., **24**, 14, 1867. Pseudomorphous after iolite, and presenting its forms.

H. = 2·5. Luster pearly. Color ash-gray. Subtranslucent. Analysis, Igelström (l. c.):

| $SiO_2$ | $Al_2O_3(Fe_2O_3)$ | MgO | CaO | $Na_2O$ | $K_2O$ | ign. | |
|---|---|---|---|---|---|---|---|
| 40·05 | 28·95 | 8·20 | 7·43 | 5·25 | 6·90 | [3·22] | = 100 |

From a gray chlorite rock at Långban, in Wermland, Sweden, distributed through it in druses as large as peas. Named from *κατασπιλάζειν* in allusion to this mode of occurrence.

**459. PARAGONITE.** Paragonit *Schafhäutl*, Lieb. Ann., **46**, 334, 1843. Pregrattit *L. Liebener*, Kenng. Ueb., 53, 1861, 1862. Natronglimmer *Germ.* Soda mica. Cossaite *Gastaldi*, Att. Acc. Torino, **10**, 189, 1874.

Massive, sometimes consisting distinctly of fine scales; also compact.

Cleavage: basal, eminent. H. = 2·5–3. G. = 2·78–2·90; ~~2·78~~ Schafhäutl. Luster strong pearly. Color yellowish, grayish, grayish white, greenish, light apple-green. Translucent; single scales transparent. Optically −. Orientation and ax. angle (70°) as in muscovite. Dispersion $\rho > v$. Tschermak.

**Comp.**—A sodium mica, corresponding to muscovite in composition $H_2NaAl_3Si_3O_{12}$ or $2H_2O.Na_2O.3Al_2O_3.6SiO_2$ = Silica 47·1, alumina 40·1, soda 8·1, water 4·7 = 100. A little potassium is often present.

**Pyr., etc.**—B.B. fusible with difficulty. The pregrattite exfoliates somewhat like vermiculite, and becomes milk-white on the edges.

**Obs.**—Paragonite constitutes the mass of the rock at Monte Campione near Faido in Canton Tessin, Switzerland, containing cyanite and staurolite; called paragonite-schist. The rock also contains garnet and black tourmaline. Also from the Ochsenkopf, Schwarzenberg, Saxony, and the Virgenthal; also forms the compact ground-mass resembling soapstone enclosing actinolite in the Pfitschthal and Zillerthal. From the Island of Syra with iolite, staurolite, cyanite. Pregratten in the Pusterthal (*Pregrattite*), Tyrol.

*Cossaite* is a compact variety, showing but little micaceous structure, first identified in an antique ring or bracelet, dug up in the neighborhood of Turin; also found at the mines of Borgofranco, near Ivrea, and at Mt. Blasier. Named for Professor Cossa, who gave the first description. Also (anal. 7) from the Colle di Bousson, Valle di Susa, in compact form with apple-green color forming layers between limestone layers.

Named from *παράγειν, to mislead.*

EUPHYLLITE *B. Silliman, Jr.*, Am. J. Sc., **8**, 381, 1849. A sodium-potassium mica apparently intermediate between muscovite and paragonite, but more basic. Structure as in mica, but laminæ not as easily separable. Laminæ rather brittle.

H. = 3·5–4·5. G. = 2·963–3·008 Silliman; 2·83 Smith and Brush. Luster of cleavage surface bright pearly, inclining to adamantine. Color white to colorless; sides faint grayish sea-green or whitish. Transparent to translucent; at times opaque or nearly so. Biaxial; axial angle 71½°, Silliman.

Tschermak identified in a specimen from Unionville, showing euphyllite and tourmaline, scales like paragonite; others with large axial angle referred to margarite, and still others with a very small axial angle. That the original material was similarly heterogeneous is not so clear.

**Anal.**—1–4, Smith and Brush, Am. J. Sc., **15**, 209, 1853.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|

| 4. " | | 40·96 | 41·40 | 1·30 | 0·70 | 1·11 | 4·26 | 3·25 | 6·23 | = 99·21 |

The specimen for analysis 2 by Smith and Brush was from the original one described by Silliman. Their results show that the earlier analysis of Crooke (Am. J. Sc., 8, 381, 1849) and those of Erni and Garret (Dana Min., 3d Ed., 362, 1850) are erroneous. Erni's and Crooke's specimens were from the same that afforded the material for analysis 2 of Smith and Brush.

Occurs associated with tourmaline and corundum at Unionville, Delaware Co., Pa. The impression of the crystals of tourmaline on the lateral surface of the euphyllite leaves a very smooth, hard-looking surface. Also in the same vicinity in aggregated laminæ, or scales, or compact masses.

Dr. Smith refers to euphyllite, with a query, a mica found by him with the emery of Asia Minor and the islands of the Grecian Archipelago which afforded him the following results (Am. J. Sc., **11**, 62, 1851, **15**, 210, 1853):

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | CaO | $K_2O$(little $Na_2O$) | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. Gumuch-dagh | 42·80 | 40·61 | 1·30 | *tr.* | 3·01 | *undet.* | 5·62 |
| 2. Kulah | 43 62 | 38·10 | 3·50 | 0·25 | 0·52 | 7·83 | 5·51 = 99·33 |
| 3. " | 42·71 | 37·52 | 2·32 | *tr.* | 1·41 | *undet.* | 5·95 |
| 4. Nicaria | 42 60 | 37·45 | 1·70 | *tr.* | 0·68 | 9·76 | 5·20 = 97·39 |

An emerald-green mica from Pipra, South Rewah, India, is referred here by Mallet (Min. India, 130, 1887) It is similarly associated with corundum and tourmaline. An analysis by Tween gave:

$SiO_2$ 43·53 $Al_2O_3$ 43·87 $Cr_2O_3$ 0·91 CaO 1·45 $K_2O$ 7·80 $H_2O$ 4·60 = 102·16

**460. LEPIDOLITE.** Violetfarbigen Zeolith (fr. Rozena) *v. Born*, Crell's Ann., **2**, 196, 1791. Lilalith (ib.) *v. Born*. Schuppenstein *Germ.* Lepidolith *Klapr.*, Schrift. Ges. Berl., **11**, 59, 1794, Bergm. J., **2**, 80, 1792, Beitr., **1**, 21, 279, 1795, **2**, 191. Lepidolite *Kirw.*, **1**, 208, 1794. Lithionglimmer *C. Gmelin*, Gilb. Ann., **64**, 371, 1820. Lithia Mica. Lithionit *Kbl.*, Taf., 54, 1853. Rabenglimmer, Siderischer Fels-Glimmer (fr. Altenberg), *Breith.*, Char., 1823, 1832, Handb., 404, 1841.

In aggregates of short prisms, often with rounded terminal faces. Crystals sometimes twins or trillings according to the mica law[1]. Also in cleavable plates, but commonly massive scaly-granular, coarse or fine.

Cleavage: basal, highly eminent. H. = 2·5–4. G. = 2·8–2·9. Luster pearly. Color rose-red, violet gray or lilac, yellowish, grayish white, white. Translucent.

Optically –. Ax. pl. usually ⊥ *b*; rarely ∥ *b* Scharizer. $Bx_a$ ($\mathfrak{a}$) inclined 1° 47′ red, and 1° 33½′ yellow (Na) to normal to *c*. Axial angle large, from 50°–72°, Elba, Tschermak. Also Scharizer[1]:

| Schüttenhofen | | Siberia | | Wolkenburg | |
|---|---|---|---|---|---|
| | $2E_r = 83^\circ\ 16'$ | | $2E_r = 72^\circ\ 42'$ | | $2E_r = 57^\circ\ 13'$ |
| " | $2E_y = 84^\circ\ 1'$ | " | $2E_y = 73^\circ\ 2'$ | " | $2E_y = 57^\circ\ 10'$ |

Indices $\beta_y$ = 1·5975 $\gamma_y$ = 1·6047

**Comp.**—In part a metasilicate $\overset{\text{I}}{R}_3Al(SiO_3)_3$ or $KLi[Al(OH,F)_2]Al(SiO_3)_3$. The ratio of fluorine and hydroxyl is variable.

Following in the line of Clarke's suggestion (p. 612), typical lepidolite may be considered as having the formula

$$\overset{\text{I}}{R}_6Al_2(SiO_4)_3 + \overset{\text{I}}{R}_6Al_2(Si_3O_8)_3. \quad \overset{\text{I}}{R} = K,Li,(AlF_2),(Al(OH)_2), \text{ also } Rb,Cs.$$

Clarke, however, prefers to consider it as consisting of equal molecules of

$$HKLiAl_2(SiO_4)_3 \text{ and } K_3Li_3(AlF_2)_3Al(Si_3O_8)_3.$$

See Clarke, l. c. (p. 613), and U. S. G. Surv., Bull. **42**, 1887; also earlier Am. J. Sc., **32**, 357, 1886; further, Tschermak, l. c., and Scharizer. Zs. Kr., **13**, 464, 1887. Scharizer regards lepidolites as isomorphous mixtures of muscovite $R_3Al_3Si_3O_{12}$ and the silicate ("lithionitsilicat") $(OH,F)_3R_4Al_3Si_5O_{16}$.

**Anal.**—1, 2, Berwerth, quoted by Tschermak, l. c. 3, Rg. Ber. Ak. Berlin, 624, 1878. 4, Scharizer, Zs. Kr., **13**, 464, 1888. 5–11, R. B. Riggs, quoted by Clarke, Am. J. Sc., **32**, 356, 1886.

**Pyr., etc.**—In the closed tube gives water and reaction for fluorine. B.B. fuses with intumescence at 2–2·5 to a white or grayish glass, sometimes magnetic, coloring the flame purplish red at the moment of fusion (lithia). With the fluxes some varieties give reactions for iron and manganese. Attacked but not completely decomposed by acids. After fusion, gelatinizes with hydrochloric acid.

**Obs.**—Occurs in granite and gneiss, especially in granitic veins, and is associated sometimes with cassiterite, red, green, or black tourmaline, amblygonite, spodumene, etc. It is often associated with muscovite in parallel position (cf. Scharizer).

Found near Utö in Sweden; at Altenberg, Chursdorf, and Penig in Saxony; Eulenlohe in the Fichtelgebirge; Yushakova in the Ural; lilac or reddish violet at Rozena (or Rožna) in Moravia; near Chanteloube, Dept. Haute Vienne, France; at Campo on Elba; brown at St. Michael's Mount in Cornwall; Argyll in Scotland; Tyrone in Ireland. In the granite of Hazáribágh, Bengal, India, with muscovite.

In the United States, common in the western part of Maine, in Hebron, Auburn, Norway, Paris, Rumford; both granular and a broad foliated varieties are found, often associated with rubellite, also with spodumene and amblygonite; at Chesterfield, Mass., with red tourmaline in the town of Peru; reported from Pownal, Durham, Yarmouth, and Freeport; granular near Middletown, Conn. The rose mica of Goshen, Mass., is muscovite (anal. 8, p. 618). Lepidolite also occurs with rubellite eight miles from San Diego, California.

Lepidolite occurs near Barkevik, Langesund fiord, as a part of the so-called pterolite which has resulted from the alteration of barkevikite (p. 403).

Named lepidolite from λεπίς, *scale*, after the earlier German name *Schuppenstein*, alluding to the scaly structure of the massive variety of Rozena.

**Ref.**—[1] See Scharizer, Zs. Kr., **12**, 5, 1886; **13**, 22, 464, 1887.

COOKEITE *G. J. Brush*, Am. J. Sc., **41**, 246, 1866.

In minute scales, and in slender six-sided prisms, sometimes vermicularly bent. Often as a coating. Cleavage, basal, perfect. Scales flexible, inelastic. H. = 2·5. G. = 2·70. Luster pearly on plane of cleavage. Color white to yellowish green. In thin scales transparent.

Approaches a hydrous lithia mica in composition. Anal.—P. Collier, l. c.:

| $SiO_2$ | $Al_2O_3$ | $Li_2O$ | $K_2O$ | $H_2O$ | $SiF_4$ |
|---|---|---|---|---|---|
| $\frac{3}{3}$ 34·93 | 44·91 | 2·82 | 2·57 | 13·41 | 0·47 $H_2O$ exp. at 100° 0·38 = 99·49 |

Three determinations of the silica obtained 35 04, 34·05, 35·71 p. c. The alumina contained a little oxide of iron.

B.B. exfoliates like vermiculite, and colors the flame intense carmine-red. In the closed tube yields water, which is at first neutral, then becomes acid by decomposing the fluoride of silicon evolved, while a ring of silica is deposited. Tube slightly etched. Fusible on thin edges, and gives blue color with cobalt solution. With phosphorus salt gives skeleton of silica. Partially decomposed by sulphuric acid.

Occurs with tourmaline and lepidolite at Hebron and Paris, Me., often as a pearly coating on crystals of rubellite, of which it appears to be a product of alteration. Probably similarly associated at Elba. Also at Pádar, Kashmir, with sapphire, green tourmaline, spodumene (La Touche, Rec. G. Surv. Ind., **23**, 59, 1890).

Named after Prof. J. P. Cooke, of Cambridge.

**461. ZINNWALDITE.** *Haidinger*, Handb., 521, 1845. Lithionit *von Kobell*, Taf., **54**, 1853. Rabenglimmer *Breith.* Lithionglimmer *pt.* Lithioneisenglimmer *Germ.*

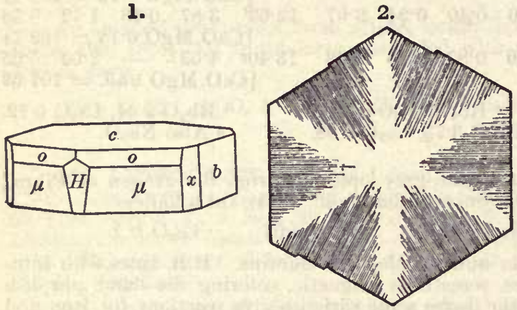
Cryophyllite *J. P. Cooke*, Am. J. Sc., **43**, 217, 1867. Polylithionit *Lorenzen*, Zs. Kr., **9**, 251, 1884.

Monoclinic. In form near biotite (meroxene).

**Forms:** *b* (010, *i-ì*), *c* (001, *O*); *H* (201, — 2-ī), *o* (112, — ½), *M* (221, — 2), *μ* (1̄11, 1), *x* (1̄31, 3-3̀).

Measured angles: $cH = 85°$, $cM = 85°$, $co = 73° 19'$, $c\mu = 81°$ to $82°$, $bx = 30° 30'$.

Twins: according to the mica law, with *c* as comp.-face. Faces *b*, *c* often bright, the others dull. A fine wrinkling common on the cleavage surfaces normal to the edges of the *b* planes (f. 2, twin). Crystals often in fan-shaped groups; in rosettes.



Figs, 1, 2, Zinnwald, Tschermak.

Cleavage: basal perfect. Laminæ tough and flexible. H. = 2·5–3. G. = 2·82–3·20. Luster often pearly. Color pale violet, or yellow to brown and dark gray. Successive layers of different colors.

Pleochroism distinct in some kinds: in dark varieties, 𝔠 and 𝔟, dark brown, 𝔞 yellowish brown or reddish; in light colored kinds, 𝔠, 𝔟 brownish gray, 𝔞 nearly colorless. Absorption 𝔠 > 𝔟 > 𝔞 (Rosenbusch). Optically —. Ax. pl. ∥ *b*. $Bx_a$ nearly ⊥ *c*. Apparent angle 𝔞 *c* = — 1° 18′ red, — 1° 4′ Na, — 0° 57′ Tl. Axial angles:

| | | | |
|---|---|---|---|
| Zinnwald | $2E_r = 50° 36'$ | $2E_y = 50° 25'$ | $2E_{gr} = 50° 5'$ Tl |
| Siberia | $2E_r = 65° 28'$ | $2E_y = 65° 19'$ | 𝔞 *c* = 4° 4′ and 4° 2′ Tschermak |

**Var.**—*Ordinary.* As described above.

*Rabenglimmer* from Altenberg is a ferruginous zinnwaldite, Tsch. Color dark gray. Axial angle nearly zero. G. = 3·15–3·19 Breith. Turner found 19·78 p. c. $Fe_2O_3$, 7·49 $K_2O$, 3 06 $Li_2O$.

*Cryophyllite* from Rockport, Mass., is naturally referred here, although of rather different composition. Crystals mostly simple. G. = 2·909. Color emerald-green axially; brownish red laterally (Cooke). Optical characters as with zinnwaldite; $2E_y = 56°$. Strongly pleochroic: 𝔠 violet, 𝔟 greenish gray.

*Polylithionite* is a lithium mica from Kangerdluarsuk, Greenland. It is related to zinnwaldite, but contains more silica and alkalies, less alumina, and almost no iron. Lorenzen obtained:

| | | |
|---|---|---|
| $2E_r = 67° 13'$ Li | $2E_y = 67° 19'$ | $2E_{gr} = 67° 51'$ |
| 𝔞 *c* = 0° 18′ | 0° 5′ to 8′ | 0° 13′ |

**Comp., Var.**—Approximates empirically to $(K,Li)_3FeAl_3Si_6O_{16}(OH,F)_2$ as given by Groth. Clarke calculates $H_2K_4Li_4Fe_3Al_8F_8Si_{14}O_{42}$. Cf. also p. 612. Analysis 1 gives $Li_2O : K_2O : H_2O : FeO : Al_2O_3 : SiO_2 : F = 1 : 1·1 : 0·5 : 1·7 : 2·1 : 7 : 3·8$.

*Cryophyllite* is somewhat different, namely, $\overset{I}{R}_6(AlF_2)Al(SiO_3)_5$ Clarke. *Polylithionite* gives the empirical formula $(Li,Na,K)_{16}F_6Al_4Si_{16}O_{43}$.

**Anal.**—1, Berwerth, Min. Mitth., 346, 1877. 2, Rg., Min. Ch., 121, 1886. Earlier analyses gave discordant results, 5th Ed., p. 315 (under lepidolite).

[a] $Mn_2O_3$. [b] $SiF_4$.

**Pyr., etc.**—Nearly as with lepidolite, but more fusible and reacts for iron.

Cryophyllite fuses in the flame of a candle; and B.B., with some intumescence to a grayish enamel (F. = 1·5-2), giving a lithia reaction. In fine powder decomposed by the dilute acids, the silica separating as a powder. The fluorine is not expelled even at a red heat.

**Obs.**—Occurs at Zinnwald and Altenberg (*Rabenglimmer*) in the Erzgebirge in connection with tin deposits; similarly in Cornwall, at St. Just, and elsewhere. In the granite of the Mourne Mts., Ireland, showing a zonal structure. the center dark green with an axial angle of 44° 4′; the border giving 52° 6′ (Sollas). Also from Siberia, exact locality unknown.

*Cryophyllite* occurs in the granite of Cape Ann, with danalite and annite. Named from *κρυός, ice*, and *φύλλον, leaf*, in allusion to its easy fusibility and foliated structure.

*Polylithionite* is from Kangerdluarsuk, Greenland, where it occurs embedded in albite with ægirite, steenstrupine, analcite.

PROTOLITHIONITE *F. Sandberger*, Unt. Erzg., 169, 1885. A lithium-iron mica from the granite of the Erzgebirge, Fichtelgebirge, etc. Color dark. Optically nearly uniaxial. The typical occurrence is that in the tourmaline-granite of Eibenstock, Saxony. Sandberger regards it as the source of the zinnwaldite, hence the name. Anal.—1, Schröder, l. c., and Jb. Min., 2, 93, 1883. 2, Niemeyer, ibid.

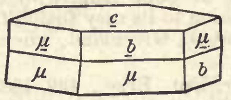

Figs. 1–5, Tschermak: 1, 2, Vesuvius, simple crystals; 3, 4, twins; 5, Greenwood Furnace, parting form with the gliding-planes ρ ($\bar{2}05$), ζ (135).

Common forms *c, b, o* (112), *μ* ($\bar{1}11$); *c* usually brilliant, also the others somewhat less so, but *o, μ*, often striated ∥ *c*, and *c* also finely striated ∥ edge *b/c*. Habit tabular or short prismatic; the pyramidal faces often repeated in oscillatory combination. Vicinal forms not uncommon. Crystals often apparently rhombohedral in symmetry since *r* ($\bar{1}01$) and *z* (132), *z′* ($1\bar{3}2$), which are inclined to *c* at nearly the same angle, often occur together; further, the zones to which these faces belong are inclined 120° to each other, hence the hexagonal outline of basal sections.

Twins[3], according to the mica law, tw. pl. a plane in the prismatic zone ⊥ *c*, sometimes contact-twins with the tw. pl. also the comp.-face, and either symmetrically or unsymmetrically situated. Also comp.-face *c* one crystal above the other, and either right-handed (f. 3) or left-handed (f. 4). Often in disseminated scales, sometimes in massive aggregations of cleavable scales.

Cleavage: basal, highly perfect; planes of separation ∥ *b* and *μ* ($\bar{1}11$) and other less definitely determined pyramids ($\bar{1}12$, 111, 114) in the unit series, as shown in the percussion-figure, Tsch. Gliding-planes *ρ* ($\bar{2}05$), *ζ* (135) shown in the pressure-figure inclined about 66° to *c*; also *σ* ($\bar{1}04$) inclined 55° to *c*, and perhaps (104). These gliding-planes yield pseudo-crystalline forms (f. 5) which are especially prominent with anomite. Etching-figures in general hexagonal in form. H. = 2·5–3. G. = 2·7–3·1. Luster splendent, and more or less pearly on a cleavage surface, and sometimes submetallic when black; lateral surfaces vitreous when smooth and shining. Colors usually green to black, often deep black in thick crystals, and sometimes even in thin laminæ, unless the laminæ are very thin; such thin laminæ green, blood-red, or brown by transmitted light; also pale yellow to dark brown; rarely white. Streak uncolored. Transparent to opaque.

Pleochroism strong; absorption $\mathfrak{b} = \mathfrak{c}$ nearly, for $\mathfrak{a}$ much stronger. Hence sections ∥ *c* (001) dark green or brown to opaque; those ⊥ *c* lighter and deep brown or green for vibrations ∥ *c*, pale yellow, green or red for vibrations ⊥ *c*. Pleochroic halos often noted, particularly about microscopic inclusions. Optically −. Double refraction strong. Ax. pl. usually ∥ *b*, rarely ⊥ *b*. $Bx_{\mathfrak{a}}$ (= $\mathfrak{a}$) nearly coincident with the normal to *c*, but inclined about half a degree, sometimes to the front, sometimes the reverse. Axial angle usually very small, and often sensibly uniaxial; also up to 50°.

Tschermak obtained on a yellow crystal from Vesuvius (meroxene) for the apparent angle between $Bx_a$ (= $\mathfrak{a}$) and the normal to *c*, − 32′ red glass (Na same); on a brown crystal + 43′ red, 43′ Na, 42′ Tl; again on a black crystal 7′ Na, 3′ green glass. On anomite from Greenwood Furnace the same angle was − 35′ Na.

He also gives the following axial angles (cf. anals. beyond) for meroxene:

| | | | | |
|---|---|---|---|---|
| Morawitza, *olive-green* | $2E_r$ = 0° to 4° | | | [$2E_{gr}$ = 9° 24′ |
| Vesuvius, *yellow* | $2E_r$ = 6° 16′ | $2E_y$ = 6° 24′ | *brown* $2E_r$ = 7° 59′ | $2E_y$ = 8° 10′ |
| " *deep brown* | $2E_y$ = 7° 51′ | $2E_{gr}$ = 8° 18′ | $2E_r$ = 9° 21′ | $2E_y$ = 10° 23′ |
| " *dark green* | $2E_r$ = 12° 22′ | $2E_y$ = 12° 48′ | $2E_{gr}$ = 13° 18′ | also $2E_y$ = 37° 30′ |
| Cherbarkul, *black* | $2E_y$ = 20° | | Albani Mts., *black* | $2E_y$ = 56° |

Anomite, L. Baikal $2E_r$ = 12° 44′ and 16°. Also $2E_{gr}$ = 15° 42′ and 12° 20′ on different parts of the same specimen. Again, $2E_r$ = 12°, 14° 12′, the axial angle diminishing with increase of iron.

Greenwood Furnace $2E_r$ = 12° 55′ red glass $2E_y$ = 12° 40′ Na $2E_{gr}$ = 12° 35′ green glass

**Comp., Var.**—In most cases an orthosilicate, and as shown by Tschermak chiefly ranging between $(H,K)_2(Mg,Fe)_4(Al,Fe)_2Si_4O_{16}$ and $(H,K)_2(Mg,Fe)_2Al_2Si_3O_{12}$. Of these the second formula may be said to represent typical biotite. The amount of iron varies widely as shown in the analyses which follow.

Biotite is divided into two classes by Tschermak:

I. MEROXENE. Axial plane ∥ *b*. II. ANOMITE. Ax. pl. ⊥ *b*. Of these, meroxene includes nearly all ordinary biotite, while anomite is, so far as yet observed, of restricted occurrence, the typical localities being Greenwood Furnace, Orange Co., N. Y., and L. Baikal in E. Siberia (see also beyond). An attempt was made by Tschermak to establish a separate composition for anomite, but the observations are too few to establish this, if indeed a uniform difference really goes with the change in optical character, which seems improbable. *Meroxene* is Breithaupt's name early given to the Vesuvian biotite. Anomite is from *ἄνομος*, *contrary to law*.

*Barytbiotite*, of Knop, is a kind of biotite from Schelingen in the Kaiserstuhl, containing 7·3 p. c. baryta, anal. 28.

A *chrome magnesia mica* (*Chromglimmer*) of a green color, from Schwarzenstein, in Zillerthal, afforded Schafhäutl (Lieb. Ann., **46**, 325, 1843) over 5 p. c. of oxide of chromium. He obtained: $SiO_2$ 47·68, $Al_2O_3$ 15·15, $Cr_2O_3$ 5·90, $Fe_2O_3$ 5·72, MnO 1·05, MgO 11·58, $Na_2O$ 1·17, $K_2O$ 7·27, $H_2O$ 2·86 = 98·38.

*Siderophyllite* of Lewis is a black mica from the Pike's Peak region, in which the magnesium is chiefly replaced by ferrous iron; cf. anal. 31, which gives the formula $3H_2O.6(K,Na,Li)_2O.21FeO.10Al_2O_3.30SiO_2$

*Haughtonite* is also characterized by the large amount of iron replacing magnesium. G. = 2·96–3·13. Fuses with difficulty to a black magnetic globule. Color dark brown to jet black. Axial angle small. Occurs mostly in granitic and gneissoid rocks, also in dioryte, at various Scottish localities, as from hornblendic gneiss of Roneval; the hill of Capval; Nishibost; from the shore of Loch-na-Muilne; Fionaven in Sutherland; Ben Stack; Rispond; Clach-an-Eoin; Kinnaird's Head, Aberdeenshire; Cove near Aberdeen; Lairg, in Sutherland; Portsoy in Banffshire. Cf. anal. 30. Named after Dr. Samuel Haughton of Dublin.

*Manganophyllite* occurs in crystals, thick tabular ∥ *c*; also tabular ∥ *b* with *m* and *o* strongly developed. Forms: *b*, *c*, *m*, *e*, *o*, *μ*, *z* (p. 627). Angles (meas., Flink): *ce* = 65° 33′, *co* = 72° 45′, *cμ* = 81° 29′, *bo* = 61° 38′, *bμ* = 60° 23′.

In aggregations of thin scales. Color bronze- to copper-red. Streak pale red. Translucent and rose-red in thin scales. Pleochroism strongly marked, but varying with the composition: ∥ *c* ($\mathfrak{b}$, $\mathfrak{c}$) colorless or pale yellowish red; ⊥ *c* ($\mathfrak{a}$) deep reddish brown. Absorption in some varieties a maximum for rays with vibrations ⊥ *c* unlike other micas. In others, which contain most manganese, absorption normal, like biotite, here $\mathfrak{a}$ red-brown, $\mathfrak{b}$ and $\mathfrak{c}$ dark brown. Certain intermediate kinds show no pleochroism (Hamberg).

In composition manganophyllite is a manganesian biotite, but varying widely in the relative amounts of manganese and other elements. Cf. anals. 33–36.

**Pyr., etc.**—In the closed tube gives a little water. Some varieties give the reaction for fluorine in the open tube; some kinds give little or no reaction for iron with the fluxes, while others give strong reactions for iron. B.B. whitens and fuses on the thin edges. Completely decomposed by sulphuric acid, leaving the silica in thin scales.

Manganophyllite becomes black upon ignition and gives a strong manganese reaction with the fluxes. Soluble in hydrochloric acid with separation of silica.

**Obs.**—Biotite is a common constituent of the crystalline rocks, granite, gneiss, mica schist, etc., being often associated with muscovite and sometimes largely taking its place. Also very common, as muscovite is not, in eruptive rocks of all ages, syenite, andesyte, trachyte, etc. Further, it occurs as a result of secondary action in certain contact rocks, and as produced by the alteration of a variety of species. It is not infrequently associated in parallel position with muscovite, the latter, for example, forming the outer portions of plates having a nucleus of biotite; sometimes in similar plates the two species are in twinning position with reference to each other (cf. Lcx., Jb. Min., 630, 1878).

Some of the prominent localities of crystallized biotite are, as follow: first of all, Vesuvius, where it is very common and occurs particularly in ejected limestone masses on Monte Somma, associated with augite, chrysolite, nephelite, humite, etc. The crystals are sometimes nearly colorless or yellow and then usually complex in form; also dark green to black. Occurs also in the Albani Mts.; Mt. Monzoni in the Fassathal, in green or greenish black crystals; Schwarzenstein in the Zillerthal and in the Pfitschthal with black tourmaline; Rezbánya and Morawitza in Hungary; Schelingen and other points in the Kaiserstuhl; the Laacher See; on the west side of L. Ilmen near Miask, etc.

In the United States ordinary biotite is common in granite, gneiss, etc., but notable localities of distinct crystals are not numerous. It occurs with muscovite (wh. see) as a more or less prominent constituent of the pegmatyte veins in Maine, New Hampshire, Massachusetts, Connecticut, Pennsylvania; also similarly in Virginia and North Carolina. Interesting specimens have been obtained at Litchfield, Me.; Acworth, N. H.; Craftsbury, Vt. (nodular masses of biotite cemented by quartz); Portland, Middletown, Branchville, Conn.; St. Lawrence Co., N. Y.; in N. Carolina. in crystals at the mica mines of Mitchell, Haywood, Yancey counties, and especially Macon County; in the Pike's Peak region in Colorado, where the variety siderophyllite was obtained.

The variety *anomite,* as already noted, is rare. The typical localities are L. Baikal in eastern Siberia, where it occurs with apatite, diopside, etc., in a coarse granular limestone on the river Sliudianka; also at Greenwood Furnace, Orange Co., New York, where it is characterized by the pseudo-crystalline forms (f. 5, p. 628), often rhombohedral, showing the gliding-planes $\rho$, $\zeta$. A few other occurrences have been noted, as in gneiss at Steinegg, Lower Austria; the nephelinyte of the Katzenbuckel; kersantyte of Michaelstein near Blankenburg in the Harz; in melilite-basalt of Alnö, Westernorrland, Sweden, etc.

*Manganophyllite* occurs in cavities filled with calcite, with tephroite, rhodonite, richterite, less often hematite, magnetite, garnet, etc., at the Harstig mine at Pajsberg, Wermland, Sweden; also at Långban and probably at Jakobsberg near Nordmark. Named from *manganese* and *φυλλον, leaf.*

See further on localities under the varieties above; also phlogopite, lepidomelane, following, which are probably to be regarded as hardly more than well characterized varieties of biotite.

Biotite is named after the French physicist, Biot (1774–1862).

**Alt.**—Biotite is often altered by the assumption of water and oxidation of the iron and many supposed species have been based upon such products; a loss of transparency, a bronze luster on the surface, etc., are early changes. Cf. below, and also under the vermiculites.

**Artif.**—See p. 613.

**Ref.**—[1] Rath, Vesuvius, Pogg., Erg. Bd., **6**, 366, 1873. He showed that the angles *cr* and *cz* are sensibly equal; measurement gave:

$$001 \wedge \bar{1}01 = 80^\circ\ 0' \qquad 001 \wedge 132 = 80^\circ\ 1' \qquad 001 \wedge 1\bar{3}2 = 80^\circ\ 0'$$

The position of Tschermak is here followed (cf. p. 620). In his original paper Tschermak assumed the fundamental angles (Rath) $cr = 80^\circ\ 0'$, $cz = 80^\circ\ 0\frac{1}{2}'$, $oo' = 57^\circ\ 10'$, which give:

$$\grave{a} : \bar{b} : \grave{c} = 0{\cdot}5777 : 1 : 3{\cdot}2772 \qquad \beta = 89^\circ\ 59\tfrac{5}{6}'$$

or, if $M = 110$ (Tschermak, Min., 1883)

$$\grave{a} : \bar{b} : \grave{c} = 0{\cdot}5777 : 1 : 2{\cdot}1932 \qquad \beta = 84^\circ\ 58'.$$

If the first axial ratio is accepted the signs of the planes must be changed, that is $r = 101$, $M = \bar{2}21$, etc. It is obvious, however, that the angles are not decisive in showing on which side the obliquity really lies, hence the position here taken, with $\beta = 90°$, is to be regarded as conventional only. With Koksharov and some other authors the position in this regard is reversed; moreover, the axis $\dot{c}$ (Kk.) has only half the length here taken, hence with him $o = \bar{1}11$, $r = 201\,(g)$, $z = \bar{1}31\,(d)$, etc. Laspeyres has proposed another position for biotite to bring it into correspondence with Koksharov's position of clinochlore. Cf. Zs. Kr., **17**, 541, 1890.

[2] Cf. Tschermak, l. c., also Phillips, Min., 103, 1837; Mgc., Suppl. Bibl. Univ., **6**, 301, 1847; Mlr. Min., 387, 1852; Kk., Min. Russl., **2**, 113, 291, **7**, 225, **8**, 5, Mem. Akad. St. Pet., 1877 (read May 17); Dx., Min., **1**, 484, 1862; Hbg., Min. Not., **7**, 15, 1866; Rath, l. c. Hbg. (l. c.) discusses the earlier results and gives a list of planes, noted by different authors, referred to the rhombohedral form. Some of the forms deduced from early observations must be regarded as doubtful.

[3] The *mica law* is here and elsewhere stated in the form given by Tschermak. Brögger prefers to regard the normal to *c* (001) as the tw. axis and the angle of revolution 120°. See Zs. Kr., **16**, 24–41, 1890, **18**, 374, 1890; also Hamberg, G. För. Förh., **12**, 585, 1890.

The following have probably been derived from biotite; still other alteration products are noted under the vermiculites, to which some of these approximate.

RUBELLAN *Breith.* is considered an altered biotite; it occurs in small hexagonal forms, of a red color, in the basalt of the Laacher See and elsewhere. Cf. Hollrung, Min. Mitth., **5**, 304, 1882.

EUKAMPTITE *Kenngott*, Ueb., 1853, 58, 1855, described under the name *Chloritähnliches Mineral* in Ber. Ak. Wien, **11**, 609, 1853. A hydrous biotite, probably a result of alteration, from Presburg, Hungary. It is between mica and chlorite in its characters.

VOIGTITE *Schmid*, Pogg., **97**, 108, 1856. Probably a hydrated biotite; it occurs in a graphic granite at Ehrenberg near Ilmenau. See 5th Ed., p. 486.

RASTOLYTE *Shepard*, Min., 1857, Appendix, p. vi; Am. J. Sc., **24**, 128, 1857. Similar to voigtite, from Monroe, N. Y.

HYDROBIOTITE *H. C. Lewis.* A hydrated biotite. The name has been similarly but more definitely used by Schrauf, Zs. Kr., **6**, 381, 1882.

PSEUDOBIOTITE *A. Knop*, Zs. Kr., **12**, 607, 1887. An altered biotite occurring in the granular limestone of the Schelinger Matten in the Kaiserstuhl. Analysis, Knop and Wagner:

| $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | MgO | $K_2O$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| $\frac{2}{2}$ 35·91 | 1·15 | 15·18 | 10·85 | 0·89 | 22 80 | 2·90 | *tr.* | 10·77 = 100·45. |

BASTONITE *Dumont*, Dx. Min., **1**, 498, 1862. A mica in large plicated plates, of a greenish brown color, greasy luster, very small optical angle, easily fusible into a black enamel, discovered by Dumont in a quartzyte from Bastogne, Belgian Luxembourg. The same mica in small pearly scales of a bronze-like color has been investigated by Klement and shown to be a somewhat altered iron mica. G. = 2·928. 2E = 10° 45′–12° 54′. Dispersion $\rho < v$. B.B. exfoliates and fuses finally to a black magnetic glass. Decomposed in hot acid. Analysis, Klement, Bull. Mus. Belg., **1**, 40, 1882.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ |

[a] Below 300° 1·61 p. c.

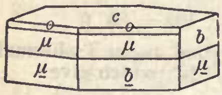
**462A. Phlogopite.** Magnesia-Mica pt. Rhombic Mica. Rhombenglimmer pt. Phlogopit (fr. Antwerp, N. Y.) *Breith.*, Handb., 398, 1841.

Monoclinic. In form and angles near biotite.

**Forms:** *b* (010, *i-ī*), *c* (001, *O*), *M* (221, − 2), *o* (112, − ½), *μ* ($\bar{1}11$, 1). Measured angles, *cM* = 85°, *co* = 73°, *cμ* = 81° 30′.

Twins as with ordinary biotite (p. 628) united by *c* (f. 1); also united by a vertical plane and then showing a fine feather-like striation ∥ edge *c/b*. Crystals often large and coarse. Usually oblong six-sided prisms, more or less tapering, with irregular sides.

1.



Cleavage: basal, highly eminent. Thin laminæ tough and elastic. Parting ∥ *σ* ($\bar{1}04$) and *ζ* (135) as with biotite, p. 628; also ∥ $\bar{1}34$ inclined about 71° to *c*; H. = 2 5–3. G. = 2·78–2·85. Luster pearly, often submetallic on cleavage surface. Color yellowish brown to brownish red, with often something of a copper-like reflection; also pale brownish yellow, green, white, colorless. Transparent to translucent in thin folia. Often exhibits asterism in transmitted light, due to regularly arranged inclusions (see below).

Pleochroism distinct in colored varieties: $\mathfrak{c}$ brownish red, $\mathfrak{b}$ brownish green, $\mathfrak{a}$ yellow. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$, Burgess. Optically −. Ax. pl. ∥ *b*. $Bx_a$ nearly ⊥ *c*. Apparent angle $\mathfrak{a}c = -24'$ red, $-9'$ green, Burgess; also 1° 19′ Natural Bridge. Axial angle small but variable even in the same specimen, from 0° to 17° 25′ for red. $2E_r = 17° 25'$ Edwards (anal. 4). Dispersion $\rho < v$. The axial angle appears to increase with the amount of iron. Cf. Silliman, 5th Ed., p. 303 and Am. J. Sc., **10**, 372, 1850.

**Comp.**—A magnesium mica, near biotite, but containing little iron. Potassium is prominent as in all the micas, and in most cases fluorine. Typical phlogopite, according to Clarke, is $\overset{I}{R}_3Mg_3Al(SiO_4)_3$, where $\overset{I}{R} = H,K,MgF$. The Burgess phlogopite corresponds very closely to $H_2KMg_3Al(SiO_4)_3 + K(MgF)Mg_2Al(SiO_4)_3$. Clarke and Schneider, Am. J. Sc., **40**, 410, 1890. Analysis 8, discussed by Penfield and Sperry, conforms to the orthosilicate formula, $H_6K_2Mg_7Al_2(SiO_4)_7$. Cf. also Clarke, l. c.

While phlogopite cannot be sharply separated from biotite, its character and method of occurrence are so far constant and peculiar that it is most naturally placed by itself, while perhaps not deserving the full rank of an independent species.

**Anal.**—1, Ludwig, Min. Mitth., 240, 1874. 2, Neminar, ib., p. 241. 3, Poppovits, ib. 4, Berwerth, ib., quoted by Tschermak, Ber. Ak. Wien, **78** (1), 31, 1878. 5–7, Rg., Min. Ch., Erg., 117, 1886. 8, E. S. Sperry, Am. J. Sc., **36**, 329, 1888. 9, 10, Clarke and Schneider, **40**, 410, 1890. 11, 12, Penfield, priv. contr.

**Pyr., etc.**—In the closed tube gives a little water. Some varieties give the reaction for fluorine in the open tube, while most give little or no reaction for iron with the fluxes. B.B. whitens and fuses on the thin edges. Completely decomposed by sulphuric acid, leaving the silica in thin scales.

**Obs.**—Phlogopite is especially characteristic of serpentine, and crystalline limestone or dolomite. It is often associated with pyroxene, amphibole, etc. Prominent localities are: Pargas, Finland, in crystalline limestone with diopside, pargasite; Åker and Sala in Sweden; Campolongo in Switzerland (Tessin), in dolomite; Ratnapura, Ceylon, etc.

Phlogopite occurs also in New York, at Gouverneur, of a brownish copper-red; at Pope's Mills, St. Lawrence Co.; Natural Bridge, Jefferson Co; colorless at Edwards, N. Y.; Oxbow. Also at Sterling Mine, Morris Co., N. J., rich yellowish brown, inclining to red, in limestone; at Suckasunny mine, N. J., deep olive-brown, inclining to yellow, in limestone; Newton, N. J., yellow, in limestone; Franklin Furnace; Lockwood, Sussex Co., N. J., deep olive-brown, like the mica of Fine, N. Y., in limestone. The crystals at Clarke's Hill, St. Lawrence Co., are very large, sometimes nearly two feet long (f. 2).

2.

At North and South Burgess, Ontario, in fine crystals, sometimes very large; also in Grenville, Buckingham, Templeton, and elsewhere in Quebec; in general, common in the crystalline limestones of the Laurentian.

Named from *φλογωπός, fire-like,* in allusion to the color.

The asterism of phlogopite, seen when a candle-flame is viewed through a thin sheet, is a common character, particularly prominent in the kinds from northern New York and Canada. It has been shown to be due to minute acicular inclusions arranged chiefly in the direction of the rays of the pressure-figure (f. 1, p. 611), producing a distinct six-rayed star; also parallel to the lines of the percussion-figure, giving a secondary star, usually less prominent than the other.

The nature of these inclusions is uncertain, and the same mineral may not always be the cause. Rose suggested cyanite, but later referred them to a uniaxial mica; rutile needles have been noted by Sandberger, and also by Lacroix; further tourmaline by Rosenbusch. Cf. the following authors:

G. Rose, Ber. Ak. Berlin, 614, Oct. 30, 1862. Sandberger, Jb. Min., **2**, 192, 1882. Lcx., Templeton, Bull. Soc. Min., **8**, 99, 1885; Ceylon, **12**, 341, 1889. Tschermak, Ber. Ak. Wien, **76** (1), 125, 1877. Rosenbusch, Mikr. Phys., 487, 1885. Lindgren, quoted by Clarke, Am. J. Sc., **40**, 411. 1890.

**Alt.**—The phlogopites are quite liable to change, losing their elasticity, becoming pearly in luster, with often brownish spots, as if from the hydration of the oxide of iron. In some cases an alteration to steatite and serpentine has been observed. A number of different "vermiculites" derived from phlogopite have been described, as noted beyond.

Aspidolite. Aspidolith *F. v. Kobell*, Ber. Ak. München, March 6, 1869.

An olive-green mica, brownish yellow in thin leaves, with pearly, submetallic luster. Occurs in aggregations of prismatic crystals. Axial angle 11° 55′. Analysis gave:

| | $SiO_2$ | $Al_2O_3$ | MgO | FeO | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| G. = 2·72 | 46·44 | 10·50 | 26·30 | 9·00 | 4·77 | 2·52 | 1·33 | = 100·86 |

The composition approaches that of a soda phlogopite, but it needs further examination.

B.B. exfoliates like vermiculite, giving water in the closed tube. In the forceps difficultly fusible to a dirty gray-white glass. Entirely decomposed by hydrochloric acid, leaving the silica in pearly scales.

Found in the Zillerthal, in Tyrol, associated with chlorite.

**462B. Lepidomelane.** *Hausmann*, Gel. Anz. Gött., 945, 1840. Annite *Dana*, Min., 1868.

In small six-sided tables, or an aggregate of minute scales. Sometimes (Bgr., Zs. Kr., **16**, 189, 1890) in distinct crystals with the forms:

*b* (010, *i*-ĭ), *c* (001, *O*), *π* (201, − 2-ĭ), *y* (043, $\frac{4}{3}$-ĭ), *o* (112, − $\frac{1}{2}$), *M* (221, − 2), *μ* (1̄11, 1). Angles (Bgr.): *cπ* = 84° 48′, *cM* = 85° 29½′, *cμ* = 81° 2½′, *MM‴* = 59° 48′, *μμ′* = 59° 12′.

Cleavage: basal, eminent, as in other micas. Somewhat brittle. H. = 3. G. = 3·0–3·2. Luster adamantine, inclining to vitreous, pearly. Color black, with occasionally a leek-green reflection. Streak grayish green. Opaque, or translucent in very thin laminæ. Ax. plane ‖ *b*. Ax. angle small, from 0° to 8°. For anal. 6, 5°–8°.

**Comp.**—Chiefly characterized by the large amount of ferric iron. In part an orthosilicate, in part a more basic compound. It can hardly be regarded otherwise than as a variety of biotite. Anal. 6 gives $(H,K)_2Fe_3(Fe,Al)_4(SiO_4)_5$.

[a] In orig. 6·40 $Na_2O$. [b] Incl. 0·04 $Li_2O$. [c] $Mn_2O_3$. [d] $Li_2O$.

**Pyr., etc.**—B.B. at a red heat becomes brown and fuses to a black magnetic globule. Easily decomposed by hydrochloric acid, depositing silica in scales; this is an important distinguishing character.

**Obs.**—A scaly-massive mineral at Persberg in Wermland, Sweden, containing embedded prisms of hornblende, the scales half a line or so across; Langesund fiord, Norway; mica-like at Abborforss in Finland; in granite in Ireland, at Ballyellin in Co. Carlow, Leinster, at Ballygihen in Co. Donegal, and at Canton, mostly in largish crystals or plates ($\frac{1}{4}$ inch across and larger). The Donegal and Leinster micas are optically uniaxial, according to Haughton. Similar iron micas occur at Litchfield, Me., Baltimore, Md., etc.

*Annite* occurs in the Cape Ann granite, with cryophyllite, orthoclase, albite, and zircon (cyrtolite).

*Lepidomelane* is named from *λεπίς, scale*, and *μέλας, black.*

PTEROLITE *Breithaupt*, B. H. Ztg., **24**, 336. Appears to be an altered lepidomelane, of a pearly luster, and a color between olive-green and liver-brown; scaly massive in texture. It occurs in the Brevik region, Norway, with astrophyllite, wöhlerite, ægirite, etc. See further p. 403.

ALURGITE *Breith.*, B. H. Ztg., **24**, 336, 1865. Massive, consisting of scales, rarely having an hexagonal outline. Cleavage: basal eminent, as in mica. H. = 2·25–3. G. = 2·984–3 Luster pearly to vitreous. Color purple to cochineal-red; in thinnest plates rose-red; streak rose-red. Transparent to translucent. Optically uniaxial. Contains much manganese, but not analyzed. Occurs with manganese ores at St. Marcel in Piedmont. Named from *ἀλουργός, purple.* It may be identical with manganophyllite, p. 629.

HELVETAN *R. T. Simmler*, Kenng. Ueb., 135, 1865, 1868. A micaceous mineral forming part of a schist and quartzyte in the gneiss formation (Alpinyte) of the Alps. H. = 3–3·5; G. = 2·77–3·03; luster pearly or waxy; color gray to whitish, reddish, greenish, violet, and copper-red; streak grayish white to reddish. In the closed tube yields little or no water.

Analysis, Simmler, Jb. Min., 348, 1868:

$SiO_2$ 67·07 $Al_2O_3$ 13·05 FeO 4·43 CaO 2·38 MgO 2·18 $K_2O$ 7·37 $Na_2O$ 1·69 $H_2O$ 1·85=100·02

It may be muscovite, impure with quartz, etc.

---

### 463. ROSCOELITE. *J. Blake*, Am. J. Sc., 12, 31, 1876. *Genth*, ib., p. 32.

In minute scales, often in stellate or fan-shaped groups. Structure micaceous.

Cleavage: basal perfect. Soft. G. = 2·92–2·94 Genth. Luster pearly. Color dark clove-brown to greenish brown, dark brownish green. Translucent. Optically biaxial, negative. Bx $\perp c$. Dispersion $\rho < v$ Dx.

**Comp.**—A vanadium mica; formula doubtful. Genth calculates $H_8K(Mg,Fe)(Al,V)_4(SiO_4)_{12}$.

**Anal.**—1, Genth (after deducting 0·85 gold, quartz, etc.), Am. Phil. Soc., **17**, 119, 1877; also earlier on less pure material, Am. J. Sc., **12**, 32, 1876. 2, 3, Roscoe, Proc. Roy. Soc., **25**, 109, 1876.

| | G. | $SiO_2$ | $V_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | FeO | MgO | CaO | $K_2O$ | $Na_2O$ | $Li_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | | 47·69 | 20·56[a] | 14·10 | — | — | 1·67 | 2·00 | — | 7·59 | 0·19 | *tr.* | 4·96= 98·76 |
| 2. | 2·902 | 41·25 | 28·85[b] | 14·34 | 1·04 | 1·45 | — | 1·96 | 0·61 | 8·25 | 0·72 | — | 0·94hygrosc.<br>[water 2·12 = 101·53 |
| 3. | | — | 28·36[b] | 13·94 | 1·23 | 0·85 | — | 2·06 | 0·62 | 8·87 | 0·92 | — | 1·22hygrosc.<br>[water 2·42 |

[a] In the earlier analyses $V_6O_{11}$ was assumed. [b] $V_2O_6$.

**Pyr., etc.**—B.B. fuses easily to a black glass. Gives with salt of phosphorus a dark yellow bead O.F., and an emerald-green bed R.F. Only slightly acted upon by acids.

**Obs.**—Occurs intimately mixed with gold in seams ($\frac{1}{10}$ to $\frac{1}{20}$ in. thick) in porphyry, and filling cavities in quartz, at the gold mine at Granite Creek, near Coloma, El Dorado Co., California; also from Big Red Ravine, near Sutter's mill, where gold was first discovered in California (*Hanks*, Min. Sc. Press, June 25, 1881). Hanks remarks that at the Granite Creek locality some 400 or 500 lbs. of the mineral have been discovered, which were wasted in the extraction of the gold.

*Genth* also describes (l. c.) a mineral occurring in the Magnolia District, Colorado, as a thin earthy incrustation, of a grayish to olive-green color on calaverite, also inclosed in quartz, and giving it a green color. An analysis of the quartz gave: Quartz 79·38, Te 1·05, Au 0·03 = 80·46; the balance (19·5 p. c.) is assumed to belong to the green mineral which forms the coloring matter. An analysis of this, after the deduction of the quartz, gave (mean of 5 partial analyses): $SiO_2$ 56·74, $Al_2O_3$ 19·62, $V_2O_3$ 7·78, FeO 3·84, MgO 2·63, $Na_2O$ 0·94, $K_2O$ 8·11 MnO,$Li_2O$ *tr.*, $H_2O$ undet. =99·66. Genth regards this as probably closely related to roscoelite, perhaps a variety.

## 2. Clintonite Group. Monoclinic.

| | | | |
|---|---|---|---|
| **464.** | **Margarite** | $H_2CaAl_4Si_2O_{12}$ | |
| **465.** | **Seybertite** | $H_3(Mg,Ca)Al_5Si_2O_{18}$ | |
| | Brandisite | | |
| **465A.** | **Xanthophyllite** | $H_8(Mg,Ca)_{14}Al_{16}Si_5O_{52}$ ? | |
| | | $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}57735 : 1 : 3{\cdot}2443$ | $\beta = 90°$ |
| **466.** | **Chloritoid** | $H_2(Fe,Mg)Al_2SiO_7$ | Triclinic? |
| **467.** | **Ottrelite** | $H_2(Fe,Mn)Al_2Si_2O_9$ ? | |

The minerals here included are sometimes called the Brittle Micas (Sprödglimmer *Germ.*). They are near the micas in cleavage, crystalline form, and optical properties, but are marked physically by the brittleness of the laminæ, and chemically by their basic character.

In several respects they form a transition from the micas proper to the chlorites. Margarite, or calcium mica, is a basic silicate of aluminium and calcium, while chloritoid is a basic silicate of aluminium and ferrous iron (with magnesium), like the chlorites.

Seybertite, brandisite, and xanthophyllite are near one another, and are regarded by Tschermak and Sipöcz as isomorphous mixtures of a silicate and aluminate

$$H_2CaMg_4Si_3O_{12} \quad \text{and} \quad H_2CaMgAl_6O_{12}.$$

For xanthophyllite the ratio 5 : 8 is given; for brandisite 3 : 4; for seybertite 4 : 5. Ottrelite is sometimes assumed to be identical with chloritoid, but recent analyses give it a much higher percentage of silica. Tschermak also includes sapphirine (p. 561) in this group.

**Ref.**—Tschermak & Sipöcz, Ber. Ak. Wien, **78** (1), Nov., 1878, or Zs. Kr., **3**, 496, 1879.

---

**464. MARGARITE.** Perlglimmer (fr. Sterzing) *Mohs*, Char., 1820, Grundr., 232, 1824. Margarite *Tyrolese min. dealers.* Corundellite (fr. Pa.), Clingmanite (fr. N. C.), *B. Silliman, Jr.*, Am. J. Sc., 8, 380, 383, 1849. Emerylite (fr. Asia Minor) *J. L. Smith*, ib., 8, 378, 1849, **11**, 59, 1851. Kalkglimmer *Germ.*

Monoclinic. Axial ratio near that of biotite.

**Forms:** $b$ (010, $i$-$\grave{i}$), $c$ (001, $O$), $\mathfrak{p}$ ($0{\cdot}10{\cdot}9$, $\frac{10}{9}$-$\grave{i}$), $\mathfrak{k}$ (116, $-\frac{1}{6}$)?, $o$ (112, $-\frac{1}{2}$), $q$ ($\bar{1}14$, $\frac{1}{4}$), $\mathfrak{q}$ ($\bar{3}{\cdot}3{\cdot}10$, $\frac{3}{10}$), $p$ ($\bar{3}37$, $\frac{3}{7}$).

Angles with $c$ (001) measured (Tschermak) and calculated from the biotite axes:

| | $\mathfrak{p}$ ($0{\cdot}10{\cdot}9$) | $\mathfrak{k}$ (116)? | $o$ (112) | $q$ ($\bar{1}14$) | $\mathfrak{q}$ ($\bar{3}{\cdot}3{\cdot}10$) | $p$ ($\bar{3}37$) |
|---|---|---|---|---|---|---|
| Meas. | 75° | 49° | 72° 21′–73° | 58° 22′ | 63° 8′ | 69°–70° |
| Calc. | 74° 38′ | 47° 30′ | 73° 1′ | 58° 35′ | 63° 1½′ | 70° 23′ |

Rarely in distinct crystals; habit thin tabular ‖ $c$. The basal planes often smooth and brilliant, also $b$, $q$ ($\bar{1}14$), the others uneven, and striated ‖ $c$. Twinning common according to the mica law, often repeated. Usually in intersecting or aggregated laminæ; sometimes massive, with a scaly structure.

Cleavage: basal, perfect. Laminæ rather brittle. H. = 3·5–4·5 G. = 2·99–3·08. Luster of base pearly, of lateral faces vitreous. Color grayish, reddish white, pink, yellowish. Translucent, subtranslucent.

Optically −. Ax. pl. ⊥ $b$. $Bx_a$ approximately ⊥ $c$, but varying more widely than other micas. $\mathfrak{a}\, c = +6° 27'$ Tschermak. Dispersion $\rho < v$. Axial angle large, from 100° to 120° in air. Refractive index $\beta = 1{\cdot}64$–$1{\cdot}65$ Becke.

**Comp.**—$H_2CaAl_4Si_2O_{12}$ = Silica 30·2, alumina 51·3, lime 14·0, water 4·5 = 100.

On the probable structural formula, cf. Clarke, Am. J. Sc., **38**, 391, 1889.

**Anal.**—1–3, J. L. Smith, Am. J. Sc., **11**, 59, 1851, **15**, 208, 1853. 4, Id., ib., **42**, 90, 1866. 5, Smith & Brush, ib., **15**, 209, 1853. 6–12, Genth, Am. Phil. Soc., **13**, 399, 1873, also other anals.; further, Smith, Am. J. Sc., **6**, 184, 1873. 13, 14, Chatard, quoted by Clarke, ib., **28**, 22, 1884. 15, J. S. de Benneville, quoted by Genth, Am. J. [a] $Fe_2O_3$. [b] Incl. $Cr_2O_3$ 0·13. [c] Mainly $Na_2O$. [d] FeO.

The material of anals. 15, 16 was derived from the alteration of andalusite and probably contained other micas besides margarite.

*Corundellite* and *clingmanite* were based on an incorrect determination of the silica in the analyses.

*Diphanite* of Nordenskiöld (Bull. Ac. St. Pet., **5**, 17) is only margarite. It occurs in hexagonal prisms with perfect basal cleavage. H. = 5–5·5 G. = 3·04–3·97. Color white to bluish.

**Pyr., etc.**—Yields water in the closed tube. B.B. whitens and fuses on the edges. Slowly and imperfectly decomposed by boiling hydrochloric acid.

**Obs.**—Associated commonly with corundum, and in many cases obviously formed directly from it: thus at the emery deposits of Gumuch-dagh in Asia Minor, the islands Naxos, Nicaria, etc. Similarly in the U. S., as noted below.

Occurs in chlorite from the Mt. Greiner, Sterzing in Tyrol, where first found; at different localities of emery in Asia Minor and the Grecian Archipelago; with the corundum of Ekaterinburg, Ural. *Diphanite* is from the emerald mines of the Ural, with chrysoberyl and phenacite.

In the U. S., at the emery mine at Chester, Mass.; at Cruger's Point, near Peekskill, N. Y., as a result of contact metamorphism in mica schist with staurolite, tourmaline, etc. (2E = 114½°), corundum is similarly associated in the same region; with corundum at Village Green, Delaware Co., Pa.; coating corundum crystals at Unionville, Chester Co., Pa. (*corundellite*); with corundum, andalusite, etc., at Bull Mt., Patrick Co., Va.: at the corundum locality in Madison Co., North Carolina (*clingmanite*); rare at the Culsagee mine near Franklin, Macon Co.; in fine laminated crystals at the Cullakenee mine near Buck Creek in Clay Co.; at Gainesville, Hall Co., Georgia, surrounding a nucleus of corundum; at Dudleyville, Alabama.

Named *Margarite* from *μαργαρίτης, pearl.* The name is attributed to Fuchs, but he nowhere published it. Von Leonhard (Handb., 766, 1826) gives it as "the current name among the Tyrolese dealers in minerals."

This species, according to Dr. Krantz of Bonn (Am. J. Sc., **44**, 256, 1867), is the *original* margarite. The specimen from Sterzing analyzed by Smith & Brush was one received so labeled from Dr. Krantz.

**Alt.**—DUDLEYITE *Genth*, from Dudleyville, Alabama, is a result of the alteration of margarite, see p. 668.

An earthy mineral is associated with and forms the matrix of the margarite of Gainesville, Georgia. Structure fine granular; soft; color between isabel-yellow and flesh color. Analysis of material containing a little margarite, Genth, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | ign. | quartz | |

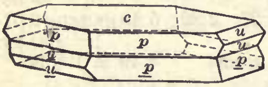
Angles on *c* (001) measured (Tschermak) and calculated as above:



| | *u* (012) | *y* (052) | *g* (091) | *p* ($\bar{3}$37) | *n* ($\bar{6}$67) | *l* ($\bar{2}$1)2 |
|---|---|---|---|---|---|---|
| Meas. | 58° 30′ | 83° 9′ | 88° | 70° 8′ | 80° 41′ | 85° 42′ |
| Calc. | 58° 35′ | 83° 2′ | 88° 3′ | 70° 23′ | 79° 54′ | 85° 38′ |

The position of the forms above is that adopted by Tschermak; if, however, the + and − quadrants be reversed, then *l* ($\bar{2}$21) corresponds to the characteristic form *M* (221) of biotite, but *q* ($\bar{1}$14) no longer finds a corresponding form as now.

Cleavage: basal, perfect. Structure foliated, micaceous. Laminæ brittle. Percussion- and pressure-figure correspond in position respectively to the pressure- and percussion-figure of mica. H. = 4–5. G. = 3–3·1. Luster pearly submetallic. Color reddish brown, yellowish, copper-red. Streak uncolored, or slightly yellowish or grayish.

Pleochroism rather feeble. Optically −. Double refraction strong. Ax. pl. ⊥ *b seybertite*; ∥ *b brandisite*. $Bx_a$ nearly ⊥ *c*. Axial angles variable, but not large, see below.

**Var.**—1. The Amity *seybertite* (called also *clintonite, holmite*, and *chrysophan*) is in reddish brown to copper-red brittle foliated masses; the surfaces of the folia often marked with equilateral triangles like some mica and chlorite. G. = 3·148 Brush. Pleochroism: 𝔠 pale brownish yellow; 𝔟 do.; 𝔞 colorless. Ax. plane ⊥ *b*. Axial angle 3°–13° Tschermak. Indices:

$\alpha = 1{\cdot}646$ $\beta = 1{\cdot}657$ $\gamma = 1{\cdot}568$ Lévy-Lcx.

2. *Brandisite* (called also *disterrite*), from the Fassathal, Tyrol, is in hexagonal prisms of a yellowish green or leek-green color to reddish gray; H. = 5 of base; of sides, 6–6·5. G. = 3·042–3·051 Kobell; 3·013–3·062 Hauer; 3·01–3·06 Liebener. Ax. plane ∥ *b*. Axial angle 15°–30° Dx.: 18°–35° Tschermak. Some of it pseudomorphous, after fassaite.

**Comp.**—For seybertite $H_3(Mg,Ca)_5Al_5Si_2O_{18} = 3H_2O.10(Mg,Ca)O.5Al_2O_3.4SiO_2$ = Silica 19·3, alumina 40·9, magnesia 23·3, lime 12·2, water 4·3 = 100. Here Mg : Ca = 8 : 3.

As stated on p. 636, Tschermak regards these minerals as isomorphous mixtures of $H_2CaMg_4Si_3O_{12}$ and $H_2CaMgAl_6O_{12}$ in the ratio of 4 : 5 for seybertite, of 3 : 4 for brandisite, and perhaps of 5 : 8 for xanthophyllite.

**Anal.**—1, 2, Brush, Dana, Min., 505, 1854. 3, 4, Sipöcz, l. c. 4, Kobell, J. pr. Ch., **41**, 154, 1847. 5, Sipöcz, l. c.

**Pyr., etc.**—Yields water. B.B. infusible alone, but whitens. In powder acted on by concentrated acids.

**Obs.**—*Seybertite* occurs at Amity, N. Y., in limestone with serpentine, associated with amphibole, spinel, pyroxene, graphite, etc.; also a chlorite near leuchtenbergite (Tschermak).

The seybertite was discovered in 1828 by Messrs. Finch, Mather, and Horton, and named *clintonite* by them on the spot, after De Witt Clinton, as stated by Mather in his Rep. Geol. N. Y., 1843. But the name was not published at the time by either of the discoverers; and Finch, the next year, 1829 (l. c.), announced the mineral under the name of *bronzite.* Clemson's name *seybertite,* after H. Seybert (1832, l. c.), has therefore priority of publication, and must be accepted as the name of the species.

*Brandisite* occurs on Mt. Monzoni in the Fassathal, Tyrol, in white limestone, either disseminated or in grouped crystals, in geodes, among crystals of fassaite and black spinel; it is often intimately associated with leuchtenbergite.

Crystals tabular ‖ c, with the faces x ($\bar{1}$02), d (134) prominent; c smooth, the other faces rough and allowing only approximate measurements. Since the angles cx, cd are nearly equal, the symmetry approximates to that of the rhombohedral system. Further, the form simulates the regular octahedron, since the angles differ but little from the octahedral angle (70° 32′), cf. above. The crystals often twins, according to the ordinary mica law, commonly made up of three individuals having the base, c, in common, the position of each differing 120° in azimuth from that of the next. Also similar trillings united in twinning position with c as comp.-face.

Cleavage: c perfect. Percussion-figure with rays parallel the edges c/x, c/d.

$c/d'$; hence occupying the same position as the pressure-figure with the true micas; while the pressure-figure corresponds in position with the percussion-figure of mica. Etching-figures on $c$ in the form of an equilateral triangle with an angle directed toward $x$. Folia brittle. H. = 4·6. G. = 3·093. Luster vitreous; on cleavage plane pearly. Color leek- to bottle-green. Transparent to translucent. Pleochroism rather feeble: $\parallel \dot{c}$ fine green; $\perp \dot{c}$ reddish brown.

Optically −. Ax. pl. $\parallel b$. Bx inclined 32′ to the normal to $c$, Bkg. Interference-figures confused, and ax. angle variable: 20½° Bkg.; 20° to 40° Dx.; 17° to 32° Tschermak. Dispersion $\rho < v$.

**Var.**—1. The original *xanthophyllite* is in crusts or in implanted globular forms, 1½ in. through, which consist of tabular crystals about a center of schist, which is also the enclosing rock. Optically negative. Ax. angle usually very small, or sensibly uniaxial, Dx.; sometimes 20°.

2. *Waluewite.* In distinct crystals showing the forms and optical characters given above. Axial angle 17° to 32°.

**Comp.**—Perhaps (Groth) $H_8(Mg,Ca)_{14}Al_{16}Si_5O_{52}$. Cf. also p. 636.

Belg., **11**, 93, 1883–84.

Monoclinic or triclinic[1]. Rarely in distinct tabular crystals, usually hexagonal in outline and twinned with the individuals turned in azimuth 120° to each other. Forms: $c$ (001, $O$), also (Tschermak) the pyramids $n$, $m_x$, and the clinodomes $e$, $j$.

Tschermak shows that if $n = 111$, then $e = 011$, $j = 0 \cdot 11 \cdot 2$, $m_x = 332$. If, however, the forms are referred to the biotite axes, the symbols and angles (on $c$) are taken as follows:

| | $e$ (0·9·10) | $j$ (051) | $n$ (9·9·10) | $m_x$ (443) |
|---|---|---|---|---|
| Meas. | 71° | 86° 30′ | 80° 6′ | 83° 25′ |
| Calc. | 71° 15 | 86° 30′ | 80° 22′ | 83° 28′ |

The form $m_x$, however, may correspond to $M$ (221) of biotite which gives $cM = 85° 38'$.

Crystals grouped in rosettes. Usually coarsely foliated massive; folia often curved or bent; and brittle; also in thin scales or small plates disseminated through the containing rock.

Cleavage: basal, but less perfect than with the micas; also imperfect parallel to planes ($m_x$) inclined to the base nearly 90° and to each other about 60°; $b$ difficult. Laminæ brittle. H. = 6·5. G. = 3·52–3·57. Color dark gray, greenish gray, greenish black, grayish black, often grass-green in very thin plates. Streak uncolored, or grayish, or very slightly greenish. Luster of surface of cleavage somewhat pearly.

Pleochroism strong: $\mathfrak{c}$ yellow-green. $\mathfrak{b}$ indigo-blue, $\mathfrak{a}$ olive-green. Optically +. Double refraction feeble. Ax. pl. nearly $\parallel b$. $Bx_a$ inclined a few degrees to the normal to $c$ (001), 12° Tschermak. Dispersion $\rho > v$, large, also horizontal. Axial angles large, in air 100° to 118°, see below.

1. The original *chloritoid* (or Chloritspath) from Kosoibrod, near Ekaterinburg in the Ural, is in large curving laminæ or plates, grayish to blackish green in color, often spotted with yellow from mixture with limonite; G. = 3·55 Fiedler, 3·557 Breith.

2. The *sismondine* is from St. Marcel; it occurs also with glaucophane at Zermatt in the Valais, Switzerland, and similarly in the Val de Chisone, Piedmont. Des Cloizeaux shows that the form is probably triclinic, since the plane angles measured on $c$ between the cleavage-directions of the 60° pyramid ($m_x$) and that of $b$ (010) differ by some 4°; thus:

St. Marcel 62° 30′, 58°, Zermatt 62° 44′, 57° 27′, Chisone 62°, 58°.

The sum of these angles is sensibly 120°. Further the ax. plane is not exactly ∥ $b$, but makes an angle of 1° to 1° 30 with this direction. Axial angles:

| | | |
|---|---|---|
| St. Marcel | $2H_{a.r}$ = 64° 34′ to 74° 6′ | $2H_{a.gr}$ = 57° to 65° 38′ |
| Zermatt | $2H_{a.r}$ = 67° 1′ to 71° 17′ | $2H_{a.gr}$ = 62° 39′ to 64° 37′ |
| | $2E_r$ = 111° 50′ to 117° 48′ | $2E_{gr}$ = 108° 44′ |
| Val de Chisone | $2H_{a.r}$ = 64° 33′ | $2H_{a.gr}$ = 57° 54′ |
| | $2E_r$ = 101° 26′ | $2E_{gr}$ = 91° 22′ |

Of the above the angles in air (2E) were measured directly; those in oil (2H) are the sum of the angles with the normal to $c$, viz.:

$$2H_{a.r} = 29° \ 34' + 35° = 64° \ 34'; \text{ also } 35° \ 4' + 39° \ 2' = 74° \ 6', \text{ etc.}$$

$$2H_{a.gr} = 25° \ 0' + 32° \ 0' = 57° \ 0' \qquad 33° \ 14' + 32° \ 24' = 65° \ 38'.$$

The fact that the dispersion is greater for one axis than for the other confirms the triclinic form.

3. *Salmite* is a manganesian variety occurring in irregular masses, having a coarse saccharoidal structure and grayish color. G. = 3·38.

3. *Masonite*, from Natick, R. I., is in very broad plates of a dark grayish green color, but bluish green in very thin laminæ parallel to $c$, and grayish green at right angles to this; G. = 3·529 Kenngott; $c$ (001) on plane of cleavage = 85°, Dx. It is evidently impure, and this must have been true of the material analyzed by Jackson (anal. 15). Named after Mr. Owen Mason.

The Canada mineral is in small plates, one-fourth inch wide and half this in thickness, disseminated through a schist, and also in nodules of radiated structure, half an inch through; G. = 3·513 Hunt. That of Gumuch-dagh resembles sismondine, is dark green in thick folia and grass-green in very thin; G. = 3·52 Smith.

**Comp.**—Empirical formula for chloritoid $H_2(Fe,Mg)Al_2SiO_7$. If iron alone is present, this requires: Silica 23·8, alumina 40·5, iron protoxide 28·5, water 7·2 = 100.

In *salmite* manganese is present replacing the ferrous iron.

The Kosoibrod chloritoid is associated with mica and cyanite. *Sismondine* occurs at St. Marcel in a dark green chlorite schist, with garnet, magnetite, and pyrites; also at Zermatt

Valais; Pregratten, Tyrol; Val de Chisone, Piedmont. Other localities of chloritoid are Ile le Groix (Morbihan); embedded in large crystals at Vanlup, Shetland; Ardennes (relatively large scales) in schists with true ottrelite; Rhode Island (*masonite*) in an argillaceous schist; Chester, Mass., in schist, with emery, diaspore, etc.; at Bull Mt., Patrick Co., Va., with corundum, cyanite, etc.; Canada, at Brome and Sutton, Brome Co., in micaceous schist, and at Leeds, Megantic Co., Quebec, in argillaceous schist; at Gumuch-dagh, Asia Minor, with emery.

**Pyr., etc.**—In a matrass yields water. B.B. nearly infusible; becomes darker and magnetic. Completely decomposed by sulphuric acid. The masonite fuses with difficulty to a dark green enamel.

**Obs.**—Occurs commonly in metamorphic schists, micaceous or argillaceous (phyllytes) in embedded crystals or scales, often grouped in fan-shaped, sheaf-like forms, also in irregular or rounded grains. Most of what has been called ottrelite probably belongs here, for the two minerals are closely related, although they cannot at present be united.

Named *Chloritoid* by Rose from the resemblance to chlorite. The name *Chloriespath*, or in English *Chlorite Spar*, has the precedence in time, but it is objectionable in form and signification, and has rightly been superseded by chloritoid. *Sismondite* was named for Prof. Sismonda of Turin.

**Ref.**—[1] Tschermak, Ber. Ak. Wien, **78** (1), Nov., 1878. Becke, Min. Mitth., **1**, 269, 1878; Foullon, Jb., G. Reichs., **33**, 220, 1883. Dx., Min., **1**, 463, 1862; Bull. Soc. Min., **7**, 80, 1884. Barrois, ibid., **7**, 37; Lcx., ibid., **9**, 42, 1886.

**467. Ottrelite.** *Des Cloizeaux* and *Damour*, Ann. Mines, **51**, 357, 1842. Phyllite *Thomson*, Ann. Lyc. N. Y., **3**, 47, 1828. Newportite *Totten*, Shepard's Min., **1**, 161, 1857. Venasquite *Damour*, Bull. Soc., Min., **2**, 167, 1879.

Monoclinic or triclinic[1]. In hexagonal crystalline scales, showing *c* (001, *O*), *b* (010, *i-ì*), *n* ($\bar{1}11$), and *j* (0·11·2). Measured angles *cn* = 79° 50′. Cf. chloritoid, p. 640. Twins as with chloritoid; simple crystals also common.

Cleavage: basal, rather perfect. H. = 6–7. G. = 3·3. Color blackish gray, greenish gray, black; streak grayish, greenish. Pleochroism not strong as with chloritoid (Dx.).

Optically +. Double refraction weak. Ax. pl. ‖ *b*. $Bx_a$ inclined to the normal to *c* (12° Tschermak). Axial angle variable. Dispersion sometimes $\rho < v$, also $\rho > v$.

**Comp.**—For ottrelite perhaps $H_2(Fe,Mn)Al_2Si_2O_9$ = Silica 38·5, alumina 32·7, iron protoxide 23·0, water 5·8 = 100. The formula, however, is doubtful, because of the difficulty of obtaining pure material, free from inclusions, for analysis. The formula $H_6(Fe,Mn)_3Al_4Si_6O_{24}$ requires: Silica 43·2, alumina 24·5, iron protoxide 25·8, water 6·5 = 100.

For *venasquite* the formula is given: $H_2FeAl_2Si_3O_{11}$ = Silica 48·4, alumina 27·4, iron protoxide 19·3, water 4·9 = 100. It occurs in masses having a lamellar and radiated crystalline structure. H. = 5·5. G. = 3·26. Color grayish black. Streak gray. Optically +. Axial angle large. Dispersion feeble. Dx.

**Pyr., etc.**—Yields water in the closed tube. Difficultly fusible to a magnetic globule. Reactions for iron with the fluxes.

**Obs.**—Occurs in small, oblong, shining scales or plates, more or less hexagonal, in argillaceous schist near Ottrez, on the borders of Luxembourg, and from the Ardennes. Ottrelite also occurs near Serravezza, Tuscany (D'Achiardi). Ottrelite schists have also been described from Tintagel in Cornwall (Hutchings, Geol. Mag., **6**, 214, 1889). *Venasquite* is from Venasque in the Pyrenees, and from Teulé, Finistère.

*Phyllite* has been described as occurring in the schist of Sterling, Goshen, Chesterfield, Plainfield, etc., in Massachusetts, and Newport, R. I., and the rock in consequence of it is called by Hitchcock (Rep. G. Mass., 4to, 594, 1841) "Spangled Mica Slate," the phyllite being the mica of the schist. The mineral in embedded scales, which is characteristic of these New England schists, is shown, however, by Wolff to be in part ilmenite (see Bull. Mus. Comp. Zool., **16**, 159, 1890). Phyllite may prove to belong to chloritoid (masonite), although the only analysis given brings it nearer to typical ottrelite.

As already remarked, analyses separate chloritoid and ottrelite widely, and the assumption that this is due to impurity of the material analyzed does not appear justified. At present it is impossible to decide to which species much so-called ottrelite belongs.

The CHLORITE GROUP takes its name from the fact that a large part of the minerals included in it are characterized by the *green* color common with silicates in which ferrous iron is prominent. The species are in many respects closely related to the micas. They crystallize in the monoclinic system, but in part with distinct monoclinic symmetry, in part with rhombohedral symmetry, with corresponding uniaxial optical character. The plane angles of the base are also 60° or 120°, marking the mutual inclinations of the chief zones of forms. The mica-like basal cleavage is prominent in distinctly crystallized forms, but the laminæ are tough and comparatively inelastic. Percussion- and pressure-figures may be obtained as with the micas and have the same orientation. The etching-figures are in general monoclinic in symmetry, in part also asymmetric, suggesting a reference to the triclinic system.

The group includes a number of species which occur ordinarily in distinct crystals or plates; these are called the ORTHOCHLORITES by Tschermak; also others which are more commonly in fine scales or indistinctly fibrous forms called LEPTOCHLORITES by Tschermak.

Chemically considered the chlorites are silicates of aluminium with ferrous iron and magnesium and chemically combined water. Ferric iron may be present replacing the aluminium in small amount; chromium enters similarly in some forms, which are then usually of a pink instead of the more common green color. Manganese replaces the ferrous iron in a few cases. Calcium and alkalies—characteristic of all the true micas—are conspicuously absent, or present only in small amount. The chlorites often occur as secondary minerals resulting from the alteration of other species, as pyroxene, amphibole, biotite, garnet, vesuvianite, etc.

The exact interpretation of the composition of the chlorites is difficult, as is also the assignment of strict lines of division between them. The empirical formulas given above are in the first part of the group those of Tschermak; in the second part chiefly those of Groth.

The ORTHOCHLORITES, including Penninite, Clinochlore, Prochlorite Corundophilite, form a distinct series characterized by a nearly constant water percentage, while the decrease in silicon and magnesium (incl. ferrous iron) is accompanied by an increase of aluminium. This is explained by Tschermak by the assumption of isomorphous mixtures in varying proportions of a magnesium silicate, $H_4Mg_3Si_2O_9$, having the composition of *serpentine*, and an aluminous magnesium silicate, $H_4Mg_2Al_2SiO_9$, which is approximately represented by a little known chlorite near corundophilite, called by Shepard *amesite*. On this view the species correspond as follows·

| | | | | |
|---|---|---|---|---|
| | Penninite | $Sp_3At_2$ | to | $SpAt$ |
| | Clinochlore | $SpAt$ | to | $Sp_2At_3$ |
| | Prochlorite | $Sp_2At_3$ | to | $Sp_3At_7$ |
| | Corundophilite | $Sp_3At_7$ | to | $SpAt_4$ |
| Also | Amesite | $SpAt_4$ | to | $At$ |

To explain the composition of the other chlorites—the Leptochlorites—two other fundamental molecules are assumed by Tschermak, viz.:

| | | | |
|---|---|---|---|
| Strigovite | $H_4Mg_2Al_2Si_2O_{11}$ | or | $(MgOH)_2.H_2Al_2SiO_7.SiO_2$ |
| Chloritoid | $H_2MgAl_2SiO_7$ | or | $Mg.H_2Al_2SiO_7$ |

Furthermore, the variations in Amesite corresponding to

| | | | |
|---|---|---|---|
| $H_4Mg_2Al_2SiO_9$ | or | $(MgOH)_2. H_2Al_2SiO_7$ | At |
| $H_4MgAl_2SiO_8$ | or | $H.MgOH.H_2Al_2SiO_7$ | At′ |
| $H_4Al_2SiO_7$ | or | $H_2.H_2Al_2SiO_7$ | At″ |

The theory here reaches a degree of complexity which makes the assumptions seem artificial and difficult to accept.

Thus of the three divisions made among the Leptochlorites

| | | | |
|---|---|---|---|
| Daphnite is regarded as | | | $(At'At)_5Sp_4$ |
| Chamosite | | | $(At'At)_3Sp_4$ |
| Metachlorite | | | $(StAt_3)_2Sp_2$ |
| Klementite | | | $(StAt_2)_2Sp$ |
| Cronstedtite and Thuringite | | | $StAt$ |
| Euralite | | | $St_4At_3$ |
| Strigovite | | | $St$ |
| Diabantite | $Ct_4Sp_7$ | | |
| Aphrosiderite | $(CtAt)_6Sp_4$ | to | $(CtAt_2)_3Sp_4$ |
| Delessite | $(CtAt)_2Sp_5$ | to | $CtSp$ |
| Rumpfite | $(CtAt'')_4Sp$ | | |

On the relation of serpentine to the chlorites see further under that species.

On the history of the names, the following remarks may be made

Werner's name chlorite was shown to include more than one species by von Kobell in 1838, and the name *chlorite* was thereupon given by him to the St. Gothard and other chlorites having 25 to 27 p c. silica, and *ripidolite* to that of Schwarzenstein and Achmatovsk having 30 to 33 p c. of silica.

In 1839, G Rose reversed the names of v. Kobell (see paper on chlorite by Varrentrapp, Pogg., **48**, 193, 1839) on the ground that v. Kobell's *ripidolite* was not so characteristically fan-shaped in aggregation as the other species. But the change was unfortunate, as both species are now known to differ but little in this respect, and it has resulted in much confusion in the science. Moreover, it violated an older claim of priority; for Werner's *blättriger Chlorit* (or *Chlorites lamellosus*), the first crystallized chlorite recognized by him (in 1800 or earlier, Ludwig's Min., **1**, 118, 1803), was the hexagonal chlorite of St. Gothard, and this should therefore, in the division, have retained the name *chlorite.*

As the term *chlorite* has become the designation of a family of minerals, it seems necessary that it should have some modified form for this species, and hence the application of *prochlorite*, from προ, *before*, and *chlorite*, in allusion to its being the earliest crystallized kind recognized. Further, in view of the confusion resulting from the double use of ripidolite, this name, adopted in the 5th edition, is dropped, and the commonly employed *clinochlore* used in its place.

**Ref.**—[1] Tschermak, Die Chloritgruppe, I. Theil, Ber. Ak. Wien, **99** (1), 174–267, 1890; II. Theil, **100** (1), 29–107, 1891. Groth, Tab. Ueb., 1889. See also Clarke, Am. J. Sc., **40**, 405, 1890, **42**, 242, 1891; Clarke proposes to regard the chlorites as mixtures of the orthosilicate molecules, $R''_2(SiO_4)_2R'_4$, where R″ = Mg,Fe,Mn and R′ = H, MgOH or $Al(OH)_2$, cf. pp. 612, 613.

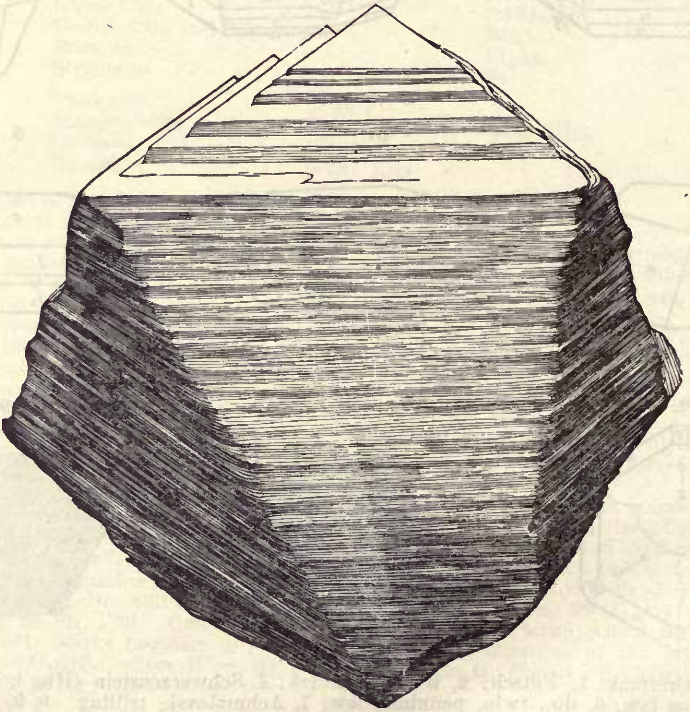
Crystals usually hexagonal in form, often tabular ∥ $c$, also prismatic by development of $m_0$, or again in 12-sided prisms (Ala); also triangular and rhombohedral resembling penninite (Zillerthal), the zones $001 : \bar{1}01$, $001 : 130$, $001 : 1\bar{3}0$ alone developed. Plane angles of the basal section = 60° or 120°, and since closely similar angles are found in the zones which are separated by 60°, the symmetry, as in the case of biotite, approximates to that of the rhombohedral system. Further, a similarity in angle may also exist in zones separated 30° from each other. For example, the angles on $c$ (001) are, for

| $k$ (011) | $\mu$ ($\bar{1}12$) | Also $w$ (267) | Again $i$ ($\bar{1}01$) | $v$ (132) | Also $\tau$ (053) |
|---|---|---|---|---|---|
| 66° 17′ | 66° 32′ | 65° 56′ | 76° 5′ | 75° 37′ | 75° 14′ etc. |

This similarity in angles in different zones may lead to uncertainty in the determination of the forms, particularly when, by twinning, one zone takes the position of another. The resemblance to rhombohedral symmetry is especially marked in the Zillerthal crystals. Pyramidal faces often striated horizontally, and repeated in oscillatory combination. The planes often irregular in distribution and rather corresponding in symmetry of development to the triclinic system.

Natural size.



West Chester, Pa.

Twins: (1) *Mica law*, tw. pl. ⊥ $c$ in the zone $cm_0$; sometimes contact-twins with $c$ as comp.-face (f. 5), the one part revolved 60° or a multiple of 60° in azimuth with reference to the other; also united by an irregular face, sometimes of two individuals, more commonly of three (f. 7) and either in contact or interpenetrating each other; such trillings may thus be formed of six sectors (figs. 8, 9), but in general not separated by sharp lines. (2) *Penninite law*, tw. pl. $c$, contact-twins also united by $c$ (f. 6), here corresponding faces differ 180° in position.

Twins also occur in which the tw. pl. appears to be a plane ⊥ *c* in the zone 001 : 130, but probably to be explained as due to the combined action of the two laws above given. The face *c* often shows a bending both in the zone 001 : 100 and 001 : 130, usually at an angle for adjacent parts of 20′, 40′ or a multiple of 20′; this can be explained by twinning with *a* (100) as the tw. ~~plane in~~ one case and (130) in the other. Repeated twinning of this kind gives rise to the often observed rosette, fan-shaped, or vermicular crystal groups. Massive, coarse scaly granular to fine granular and earthy.

Cleavage: *c* highly perfect. Laminæ flexible, tough, and but slightly elastic. Percussion-figure and pressure-figures orientated as with the micas (p. 611). Etching-figures on *c* in part monosymmetric, in part also asymmetric, and then suggesting a molecular structure corresponding to the triclinic system; the former triangular with vertices (60°) directed forward, and other angles rounded; the latter equilateral trianges with one angle rounded, and either right- or left-handed. H. = 2–2·5. G. = 2·65–2·78. Luster of cleavage-face somewhat pearly. Color deep grass-green to olive-green; pale green to yellowish and white; also rose-red. Streak greenish white to uncolored. Transparent to translucent. Pleochroism not strong, for green varieties:

| | $\parallel \mathfrak{a}$ | $\parallel \mathfrak{c}$ |
|---|---|---|
| Achmatovsk | dark green | greenish yellow |
| " | " " | brownish yellow |
| Texas | emerald-green | hyacinth-red |
| " | leek-green | yellowish green |
| Pfitsch | " | greenish yellow |
| Ala | olive-green | " " |

Optically usually +. Ax. pl. in most cases ∥ *b*. $Bx_a$ inclined somewhat to the normal to *c*, forward; for Achmatovsk 2° 30′. Dispersion $\rho < v$. Axial angles variable, even in the same crystal, sometimes sensibly uniaxial. Tschermak gives:

Achmatovsk $2E = 32°$ ($\beta = 1·588$ Lévy-Lcx.) ∴ $2V = 20°$ and $c\mathfrak{c} = +2° 30'$
Also " $2E = 1°, 5°, 12°$ and intermediate values.
Texas $2E = 20°$ to $60°$ Ala 44° to 65°
West Chester $2E = 89° 41'$ [$\beta = 1·583$] ∴ $2V = 51° 30'$ $\mathfrak{c}c = 7° 10'$
Zillerthal $2E = 83° 0'$ ∴ $2V = 48° 30'$ $\mathfrak{c}c = 6° 45'$

The angles measured in certain cases, between the optic axes (*A*, *B*) and the normal to *c*, are as follows (Tschermak):

| | *Ac* | *cB* | 2E | $\beta$ |
|---|---|---|---|---|
| West Chester | 58° 5′ | 29° 40′ | 87° 45′ | 1·580 red glass |
| " | 63° 45′ | 31° 9′ | 94° 54′ | 1·593 $CuSO_4$ |
| " | ∴ *A′c* = 32° 30′ | 18° 15′ | $2V_r = 50° 45'$ | $c\mathfrak{c} = 7° 8'$ red |

Indices:

$\alpha = 1·585$ $\beta = 1·588$ $\gamma = 1·596$ Lévy-Lcx.

Ax. pl. also rarely ⊥ *b*. Observed in a crystal from Texas and from Pfitsch, the latter with 2E = 48°. Bx ⊥ *c*. Other parts of the same crystal gave ax. pl. ∥ *b*, Bx oblique to *c*, and 2E = 64.

Ax. pl. also sometimes (West Chester) abnormally makes an angle of 90° or of 30° (twin) with its usual position, Bx ⊥ *c* and 2E = 50° to 60°. In some crystals parts with both the normal and this abnormal orientation are present and separated by irregular boundaries. See also below.

**Var.**—1. *Ordinary;* green clinochlore, passing into bluish green; (*a*) in crystals, as described, usually with distinct monoclinic symmetry; (*b*) foliated; (*c*) massive.

Among the varieties described by Tschermak is a "mimetic clinochlore" from the Zillerthal and Pfitschjoch. This occurs in druses of tabular crystals of distinct rhombohedral habit; often complex twins according to both the penninite and mica laws; etching-figures hexagonal, corresponding in symmetry to the rhombohedral form; optically +, uniaxial to distinctly biaxial with ax. pl. ∥ *b*, also abnormally ⊥ *b*. The maximum angle observed is 42° ($Ac = 26°$, $cB = 16°$), hence if $\beta = 1{\cdot}583$ (West Chester), $2V = 26°$, and $\mathfrak{c}\,c = 3°$. Color emerald-green to leek-green.

It is inferred that the true character is biaxial with a considerable axial angle, while the variations are due to twinning, the successive biaxial layers producing the uniaxial character (cf. p. 651). This chlorite hence occupies a place intermediate between ordinary clinochlore and penninite, but inclining to the latter. This shows, moreover, that no sharp line can be drawn between them, but they may be considered as different forms of the same species. Its composition is given in anal. 1, under penninite.

2. *Leuchtenbergite.* A variety containing usually little or no iron, see anals. 14–19. Color white, pale green, yellowish; often resembles talc. Commonly in hexagonal tables; often twins. Optically +. Ax. pl. ∥ *b*. Ax. angle small, sometimes sensibly uniaxial, again $2E = 6°$, also 0° to 15° Ural; 14°, again 10° to 29° Amity; 2°–12°, 22°, 42° Nasiamsk (with waluewite); 5°–21° Traversella.

Named after Duke Maximilian v. Leuchtenberg.

3 *Kotschubeite.* A variety containing several per cent. of chromium oxide. Crystals rhombohedral in habit. Color rose-red, often twins, sometimes trillings with six sectors, like f. 9 (California). Pleochroism strong: ∥ *c* ($\mathfrak{a}$ $\mathfrak{b}$) dark blue-violet; ⊥ *c* ($\mathfrak{c}$) bright carmine red, Ural, Tschermak; ∥ *c* purplish, ⊥ *c* yellowish red, California, Lindgren. Optically +. Ax. pl. ∥ *b* (⊥ *b* Prendel). Axial angle variable, sometimes apparently uniaxial and like the "mimetic clinochlore" (see above); also $2E = 28°–29°$ Prendel; 30° Lindgren. Named after the Russian Count P. Kochubei.

A part of the so-called kämmererite from Texas belongs here (Tschermak), being distinctly biaxial; but this is not significant since there is the same transition between the uniaxial and biaxial kinds as between the uniaxial and positive penninite and the biaxial clinochlore.

4. *Manganiferous.* Manganchlorit *Hamberg*, G. För. Förh., **12**, 580, 1890. A chlorite from the Harstig mine near Pajsberg. Sweden, is peculiar in containing 2·3 p. c. MnO (anal 9); it is also like the "mimetic clinochlore" intermediate between clinochlore and penninite. In aspect resembles manganophyllite, with which it occurs, but has a lighter reddish color. Apparent form a steep rhombohedron inclined 83° 37′ to *c*, which referred to the penninite axis has the symbol $50\bar{5}2$ $(\frac{5}{2})$, calc. 84° 20′; the subordinate forms *c* (0001) and $05\bar{5}4$ $(-\frac{5}{4})$ also observed. Optically −. Bx almost ⊥ *c*. Ax. pl. nearly ∥ *b* (010), but a variation of 8° was noted. Double refraction and pleochroism weak. Examined microscopically, some of the lamellæ prove to be distinctly doubly refracting and biaxial, and the conclusion is reached that the crystals are built up of lamellæ, corresponding to clinochlore, in twinning position (revolved 120°) to each other, and strictly asymmetric in optical character. The fact that the etching-figures on clinochlore, are often asymmetric and hence suggest a triclinic form for the species has already been noted.

**Comp.**—Normally $H_8Mg_5Al_2Si_3O_{18} = 4H_2O.5MgO.Al_2O_3.3SiO_2$ = Silica 32·5, alumina 18·4, magnesia 36·1, water 13·0 = 100. Ferrous iron usually replaces a small part of the magnesia, and the same is true of manganese rarely; sometimes chromium replaces the aluminium.

On Tschermak's view of the composition of clinochlore, see p. 643. The above formula corresponds to equal parts of $H_4Mg_3Si_2O_9$ and $H_4Mg_2Al_2SiO_9$ or SpA. For Sp : At = 2 : 3, he calculates: $SiO_2$ 30·3, $Al_2O_3$ 22·0. MgO 34·7, $H_2O$ 13·0 = 100. To this analyses 4, 14, approximate most closely. The variation, however, is in any case small.

Clarke and Schneider (Am. J. Sc., **40**, 405, 1890) found that on treating clinochlore from West Chester (anal. 13) with dry hydrochloric acid gas at 383°-412° for 19 hours the amounts of the oxides converted in chlorides were as follows:

Clinochlore MgO 13·46 $R_2O_3$ 4·24 $SiO_2$ 0·92

Another determination gave 13·36 p. c. of MgO (after 58 hours). This amount is inferred to exist as the group MgOH, the remainder of the hydroxyl combined as $Al(OH)_2$, and the conclusion is reached that clinochlore is probably a mixture of the molecules $Mg_2(SiO_4)_2(MgOH)_3H$ and $Mg_2(SiO_4)_2(Al(OH)_2)_3H$ in the ratio of 1 : 1, for which the required composition is calculated: $SiO_2$ 31·1, $Al_2O_3$ 19·8, MgO 36·3, $H_2O$ 12·8 = 100. Of the water present it was found that between 250°–300°, 0·95 p c. was driven off; 383°–412°, 0·49 p. c.; at a red heat 11·74; white heat 0·42. Hence the water is essentially all water of constitution.

**Pyr., etc.**—Yields water. B.B. in the platinum forceps whitens and fuses with difficulty on the edges to a grayish black glass. With borax, a clear glass colored by iron, and sometimes chromium. In sulphuric acid wholly decomposed. A variety from Willimantic, Ct., exfoliates in worm-like forms, like vermiculite.

**Obs.**—Occurs in connection with chloritic and talcose rocks or schists and serpentine; sometimes in parallel position with biotite or phlogopite (cf. Tschermak, l. c., p. 256). Observed as a result of the alteration of vesuvianite from Zlatoust, Tschermak, Ber. Ak. Wien, **49** (1), 348, 1864.

Prominent localities are: Achmatovsk in the Ural; Ala in Piedmont; the Zillerthal; Zermatt in Switzerland; Marienberg in Saxony; massive, granular at Zöptau, Moravia; coarse to fine granular at Felling in Lower Austria; also chlorite schists from various localities; Markt Leugast, Bavaria. A manganesian variety occurs at Pajsberg, Sweden.

In the U. States, at West Chester, Penn., in large crystals and plates; also Unionville and Texas, Penn.; at the magnetic iron mine at Brewster, N. Y., in part changed to serpentine.

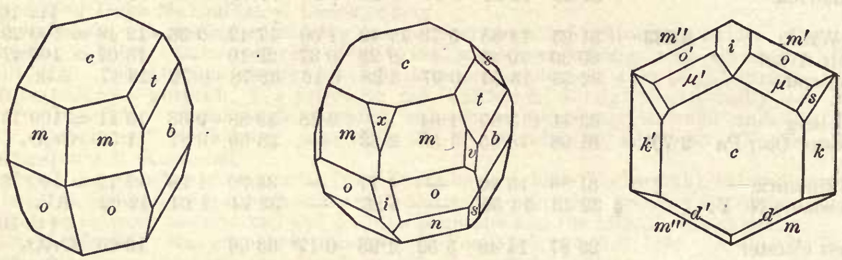
*Leuchtenbergite* comes from the Shishimskaya Mts. near Zlatoust in the Ural; it is partly in large crystals, and partly quite small, embedded in steatite; the crystals are mostly opaque and altered externally, and contain in this outer part from 9·30 to 10·75 p. c. of water. The mineral contains minute garnets and some other crystals as impurities. A similar variety of clinochlore occurs with amphibole, phlogopite, fluorite, graphite at Amity, N. Y.; also with the seybertite of Amity and the xanthophyllite of Nasiamsk, Ural; with fassaite and brandisite from the Fassathal; with magnetite at Traversella. The white chlorite from Mauléon also belongs here.

*Kotschubeite* is from the district of Ufaleisk in the southern Ural.

**Ref.**—[1] Achmatovsk, Min. Russl., **2**, 7 *et seq.*, 1857. The position is that of Tschermak, and the fundamental angles are those taken by him. With Koksharov, $m_0 = 110$, $o = \bar{1}11$, etc., and from the fundamental angles $001 \wedge 110 = 66° 3'$, $110 \wedge 1\bar{1}0 = 54° 23'$, $001 \wedge \bar{1}11 = 77° 53\frac{1}{2}'$ the axial ratio in this position is calculated, viz.:

$$\grave{a} : \bar{b} : \acute{c} = 0{\cdot}57738 : 1 : 0{\cdot}85312; \qquad \beta = 62° 50\tfrac{5}{6}'$$

Figs. 11–13 show the Achmatovsk clinochlore in the position referred to.



Figs. 11–13, Achmatovsk, Kk.

Naumann made $m_0 = \bar{1}11$ and $o = 110$; other positions have been taken by Mallard (cf. Tschermak). Tschermak's position brings out the relation between the micas and chlorites, the lateral axes being the same and the vertical axes for biotite and clinochlore in the ratio of 10 : 7.

Rhombohedral in form, but strictly pseudorhombohedral and monoclinic Mallard, Tschermak[1]. Taken as rhombohedral, axis $\acute{c} = 3{\cdot}4951$, $0001 \wedge 10\bar{1}1 =$ *76° 5′ Cooke[2].

**Forms**[2]: y ($20\bar{2}5$, $\frac{2}{5}$) v ($26{\cdot}0{\cdot}\overline{26}{\cdot}27$, $\frac{26}{27}$) s ($90\bar{9}8$, $\frac{9}{8}$) q ($17{\cdot}0{\cdot}\overline{17}{\cdot}6$, $\frac{17}{6}$)
c (0001, *O*) p ($5{\cdot}0{\cdot}\bar{5}{\cdot}12$, $\frac{5}{12}$) r ($10\bar{1}1$, *R*) ε ($60\bar{6}5$, $\frac{6}{5}$) γ ($60\bar{6}1$, 6)
a ($11\bar{2}0$, *i*-2) μ ($40\bar{4}7$, $\frac{4}{7}$) j ($31{\cdot}0{\cdot}\overline{31}{\cdot}30$, $\frac{31}{30}$) σ ($50\bar{5}4$, $\frac{5}{4}$) ω ($13{\cdot}0{\cdot}\overline{13}{\cdot}1$, 13)
φ ($4{\cdot}0{\cdot}\bar{4}{\cdot}13$, $\frac{4}{13}$) ψ ($9{\cdot}0{\cdot}\bar{9}{\cdot}10$, $\frac{9}{10}$) ξ ($33{\cdot}0{\cdot}\overline{33}{\cdot}31$, $\frac{33}{31}$) η ($21{\cdot}0{\cdot}\overline{21}{\cdot}4$, $\frac{21}{4}$)

Also ρ ($11\bar{2}4$, $\frac{1}{2}$-2) and χ ($11\bar{2}2$, 1-2); z ($10\bar{1}3$, $\frac{1}{3}$).

Further, on kämmererite, if $\rho = 30\bar{3}1$ and $c\rho =$ *84° $35\frac{1}{3}'$: $\acute{c} = 3{\cdot}0475$; $0001 \wedge 10\bar{1}1 = 74° 8\frac{1}{6}'$ Kk.

Forms: c, m, u ($30\bar{3}4$), x ($50\bar{5}4$), y ($40\bar{4}3$), z ($30\bar{3}2$), ρ ($30\bar{3}1$), $m_x$ ($40\bar{4}1$), s ($50\bar{5}1$).

Referred to the penninite axis, ρ becomes $13{\cdot}0{\cdot}\overline{13}{\cdot}5$, and the other symbols are correspondingly complex.

The penninite forms, as shown by Tschermak (l. c., p. 70), may be referred to the clinochlore axes. Thus r ($10\bar{1}1$) corresponds to $\bar{1}01$, for which we have: $001 \wedge \bar{1}01 = 76° 5'$, while $0001 \wedge 10\bar{1}1 = 76° 5'$ penninite; similarly for other forms. Moreover, on penninite forms occur in the same zone which in clinochlore belong to three different zones, as is true of the "mimetic clinochlore" from the Zillerthal. Furthermore, as all possible intermediate degrees are observed between the distinctly monoclinic, biaxial clinochlore and the apparently rhombohedral, uniaxial penninite, the conclusion is reached that the two are essentially the same. The form and optical characters of penninite are then due to the twinning of lamellæ grouped, according to the mica law, in positions making angles of 60° or 120° with one another.

The fact that three sections of a biaxial mica placed one over the other with their axial planes at angles, respectively, of 60° yield a uniaxial interference-figure is well known (cf. Reusch, Cooke, ref. on p. 614); a similar grouping will explain the optical properties of penninite.

As the matter stands at present, therefore, although it is convenient to discuss clinochlore and penninite separately, they must be regarded as essentially the same species. This conclusion was earlier reached by Mallard, but from a somewhat different standpoint.

Tschermak argues from the facts stated that in these chlorites there are present two isomorphous substances, one of which is optically − with dispersion $\rho > v$, the other + with dispersion $\rho < v$; in the optically − penninite the former predominates. This optically negative substance is regarded as probably serpentine (see further that species).

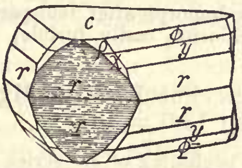

Figs. 1, 2, 4, Texas, Penn., Pirsson. 3, Zermatt, Tschermak. 5, Zillerthal, Id.
6, *Kämmererite*, Kk.

$c\phi = 51° \; 9'$ $c\psi = 74° \; 36\frac{1}{2}'$ $c\sigma = 78° \; 47'$ $c\omega = 88° \; 54\frac{1}{2}'$

$cy = 58° \; 13\frac{1}{2}'$ $cr = {}^*76° \; 5'$ $cw = 85° \; 17'$ $c\rho = 60° \; 13'$

$cp = 59° \; 16'$ $cs = 77° \; 35'$ $c\gamma = 87° \; 38'$ $c\chi = 74° \; 2'$

$c\mu = 66° \; 33\frac{1}{2}'$ $c\epsilon = 78° \; 20'$

Twins very common, according to the *penninite law:* tw. pl. *c*, cf. f. 1–4. Habit rhombohedral: sometimes thick tabular with *c* prominent, again steep rhombohedral; also in tapering six-sided pyramids. Rhombohedral faces often horizontally striated. Crystals often in crested groups. Also massive, consisting of an aggregation of scales; also compact cryptocrystalline.

Cleavage: *c* highly perfect. Laminæ flexible. Percussion-figure and pressure-figure as with clinochlore but less easy to obtain; not elastic. Etching-figures hexagonal or triangular; seldom monosymmetric or asymmetric. H. = 2–2·5. G. = 2·6–2·85. Luster of cleavage surface pearly; of lateral plates vitreous, and sometimes brilliant. Color green, emerald-green, apple-green, grass-green, grayish green, leek-green, olive-green; also reddish, violet, rose-red, pink, grayish red; occasionally yellowish and silver-white. Transparent to subtranslucent.

Pleochroism distinct: on olive-green crystals, ∥ *c* emerald-green; ⊥ *c* brownish red, brown, or yellow; on leek-green crystals, blue-green and yellow; on kämmererite, ∥ *c* violet, ⊥ *c* hyacinth-red, Tschermak. Optically +, also −, and sometimes both in adjacent laminæ of the same crystal. Usually sensibly uniaxial, but sometimes distinctly biaxial, occasionally 2E = 61°. Dispersion, when biaxial, $\rho < v$ for + crystals, $\rho > v$ for − crystals. Uniaxial and biaxial portions seen in the same section. Axial figure generally wanting in sharpness, and often quite indistinct. Sometimes a sharply-outlined kernel which is uniaxial while the border is biaxial with 2E = 36°, the latter probably to be referred to clinochlore.

Indices 1·576 and 1·579 Lévy-Lcx.

**Var.**—1. *Penninite.* As first named, it included a green crystallized chlorite from the Pennine Alps.

*Hydrotalc* of Necker is penninite from the Binnenthal, in the Valais. Optically positive, Dx. Most of the penninite from Zermatt, and that of the Binnenthal and Tyrol, is optically negative; some crystals of Zermatt, and those of Ala, positive; and some plates from Zermatt consist of positive and negative laminæ united, Dx.

2 *Kämmererite.* In hexagonal forms bounded by steep six-sided pyramids, cf. above. Color kermes-red; peach-blossom-red. Pleochroism distinct. Optically − from Bisersk, + Texas. Uniaxial or biaxial with axial angle up to 20°. Crystals from Texas are often mixed with clinochlore, and sometimes a crystal is traversed by a band of clinochlore whose optic-axial angle is 60° to 70° Dx.

The original kämmererite was a reddish violet micaceous mineral from L. Itkul, Bisersk, Perm, Russia, partly in 6-sided prisms. Named after the mining director A. Kämmerer of St. Petersburg.

*Rhodophyllite* of Genth and *chrom-chlorite* of Hermann are the same, from Texas, Pa. G. = 2·617–2·62. *Rhodochrome* is a compact or scaly-granular variety, originally from L. Itkul, Siberia, having a splintery fracture, with G. = 2·66–2·67. Color deep green; but violet, rose or peach-blossom-red in thin splinters, whence the name.

3. *Loganite* of Hunt (= *Pseudophite* of Kenngott) is near penninite in composition. It comes from Calumet Falls, Canada, and has the form, angles, and cleavage of amphibole (see p. 398); G. = 2·60–2·64; color clove-brown to chocolate-brown; luster dull (anal. 18).

*Pseudophite* of Kenngott (Ber. Ak. Wien, **16**, 1855) has the composition of loganite, but is compact massive, without cleavage, and resembles serpentine (whence the name from *πσεύδός*, *false*, and *ophite* or serpentine); H. = 2·5; G. = 2·75–2·77; luster weak; color grayish green, olive-green, pistachio-green; feel unctuous. It forms the gangue of enstatite. Berg Zdjar in Aloisthal, Moravia. In the occurrence of a massive form, penninite is thus like talc, pyrophyllite, and other related species.

Pseudophite also occurs as a pseudomorph after feldspar (anal. 16, 17). The material of anal. 19 was a light green compact chlorite, easily fusible; it was from the Zoutpans Mts., Griqualand West.

**Comp.**—Essentially the same as clinochlore, $H_8(Mg,Fe)_5Al_2Si_3O_{18}$ = Silica 32·5, alumina 18·4, magnesia 36·1, water 13·0 = 100.

Tschermak places penninite at the beginning of the series, varying from Sp : At = 3 : 2 to SpAt. The latter corresponds to the empirical formula above; the former requires: $SiO_2$ 34·8, $Al_2O_3$ 14·6, MgO 37·5, $H_2O$ 12·4 = 100.

**Pyr., etc.**—In the closed tube yields water. B.B. exfoliates somewhat and is difficultly fusible. With the fluxes all varieties give reactions for iron, and many varieties react for chromium. Partially decomposed by hydrochloric and completely by sulphuric acid.

**Obs.**—Occurs with serpentine in the region of Zermatt, Valais, near Mt. Rosa, especially in the moraines of the Findelen glacier; crystals from Zermatt are sometimes 2 in. long and 1½ in. thick; also at the foot of the Simplon; at Ala, Piedmont, with clinochlore; at Schwarzenstein in Tyrol; at Taberg in Wermland; at Snarum greenish and foliated, called *steatite of Snarum*. In the green schists of the Höhenzug which separates the Zillerthal from the Pfitschthal in Tyrol.

*Kämmererite* is found at the localities already mentioned; also near Miask in the Ural; at Haroldswick in Unst, Shetland Isles. In large crystals up to 2 cm. in length enclosed in the talc in crevices of the chromite from Kraubat, Styria. Abundant at Texas, Lancaster Co., Pa., along with clinochlore, some crystals being embedded in clinochlore, or the reverse. Also in N. Carolina, with chromite at Culsagee, Macon Co.; Webster, Jackson Co.; Hampton's, Mining Creek, Yancey Co.; Bakersville, Mitchell Co., and other points.

**Ref.**—[1] Texas, Penn., Am. J. Sc., **44**, 201, 1867. Dx. gives for Zermatt penninite $cr =$ 76° 10′–20′; Tschermak obtained 76° 5′. [2] Dx., l. c.; Cooke, l. c.; Mallard, Ann. Mines, **10**, 151, 1876; Tschermak, Ber. Ak. Wien, **99** (1), 240, 1890; Pirsson, Am. J. Sc., **42**, 408, 1891. Cf. also Mld. (ref. p. 650) on the relation of clinochlore and penninite.

TABERGITE *Scheerer*, Pogg., **71**, 448, 1847. From Taberg, Wermland (*Blue talc* of Werner, and called also *mica-chlorite*); a bluish green or green chlorite near penninite. According to Des Cloizeaux's optical observations, it is in part uniaxial and positive like true penninite. But in other cases uniaxial and biaxial plates are combined and negative and positive also; and the axial divergence of the biaxial plates varies from 1° to 33°. Tschermak (Ber. Ak. Wien, **99** (1), 262, 1890) concludes that it represents an intimate mixture of clinochlore or penninite and phlogopite. Analysis, A. Paltauf, quoted by Tschermak, ib., **100** (1), 45, 1891:

| G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ | F |
|---|---|---|---|---|---|---|---|---|---|---|

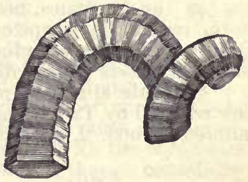
Monoclinic. In six-sided tables or prisms, the side planes strongly furrowed and dull. Crystals often implanted by their sides, and in divergent groups, fan-shaped, vermicular, or spheroidal. Also in large folia. Massive, foliated, or granular.



H. = 1–2. G. = 2·78–2·96. Translucent to opaque; transparent only in very thin folia. Luster of cleavage surface feebly pearly. Color green, grass-green, olive-green, blackish green; across the axis by transmitted light sometimes red. Streak uncolored or greenish. Laminæ flexible, not elastic.

Pleochroism distinct: vibrations $\parallel c$ yellow-green; $\perp c$ brownish. Optically + in most cases, rarely — (Floitenthal). Bx inclined to the normal to $c$ some 2°. Axial angle small, often nearly uniaxial; again 2E = 23°, 30°. Dispersion $\rho < v$.

**Comp.**—According to Tschermak to be regarded as a molecular mixture of $H_4(Mg,Fe)_3Si_2O_9$ and $H_4(Mg,Fe)_2Al_2SiO_9$ in the ratio of 2 : 3 to 3 : 7; the empirical formula on page 643 corresponds to the former ratio. Ferrous iron is usually, but not always, present in large amount.

The *helminthe* of Volger occurs in slender vermiform crystallizations like fig. 1 (whence the name), transversely foliated, penetrating quartz and feldspar. The figure is from a New Hampshire specimen described by O. P. Hubbard, and may be one of the other species of chlorite.

**Pyr., etc.**—Same as for clinochlore.

**Obs.**—Like other chlorites in modes of occurrence. Sometimes in implanted crystals, as at St. Gothard, enveloping often adularia, etc.; Mt. Greiner in the Zillerthal, Tyrol; Rauris in Salzburg; Traversella in Piedmont; at Mtn. Sept Lacs and St. Cristophe in Dauphiné; in Styria, Bohemia. Also massive in Cornwall, in tin veins (where it is called *peach*); at Arendal in Norway; Salberg and Dannemora, Sweden; Dognacska, Hungary. Occasionally formed from amphibole (Tschermak, Ber. Ak. Wien, **53** (1), 521, 1866). In Scotland at various points (anal. 9–11); other specimens (l. c.) with but 24 p. c. $SiO_2$ approximate to corundophilite

In the U. States, near Washington (anal. 13, 14); on Castle Mt., Batesville, Va., a massive form resembling soapstone, color grayish green, feel greasy; Steele's mine, Montgomery Co., N. C; also with corundum at the Culsagee mine, in broad plates of a dark green color and fine scaly; it differs from ordinary prochlorite in the small amount of ferrous iron.

Chloritic alteration-products of pyrope described by Lemberg (Zs. G. Ges., **27**, 531, 1875) are referred by Tschermak (l. c., p. 87) to penninite. Lemberg's analyses are as follows: 1, unaltered pyrope; 2, enclosing chloritic shell; 3–5, complete pseudomorphs:

| | $SiO_2$ | $Al_2O_3$ | $Cr_2O_3$ | $Fe_2O_3$ | MgO | Ca | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. | 40·60 | 22·70 | — | 9·34 | 21·47 | 4·23 | 1·66 | = 100 |
| 2. | 33·78 | 16·76 | — | 8·44 | 28·54 | 0·52 | 11·96 | = 100 |
| 3. | 33·82 | 13·58 | 1·97 | 5·15 | 32·93 | 0·37 | 10·42 | = 98·24 |
| 4. | 33·19 | 15·29 | — | 6·04 | 33·13 | — | 12·64 | = 100·29 |
| 5. | 33·63 | 14·17 | — | 5·26 | 33·65 | — | 13·29 | = 100 |

*Grengesite* from Grängesberg in Dalarne, Sweden, occurs partly in hexagonal crystallizations, more or less radiately grouped, and probably results, Erdmann observes (Lärobok Min., 374, 1853).

from the alteration of pyroxene. Erdmann spells the name *Grängesite.* Specific gravity 3·1; color dark green. An analysis by Hisinger gave:

$SiO_2$ 27·81 $Al_2O_3$ 14·31 FeO 25·63 MnO 2·18 MgO 14·31 $H_2O$ 12·55 = 96·79

GROCHAUITE *Websky*, Zs. G. Ges., **25**, 395, 1873.
Monoclinic? In small six-sided, tabular crystals, rough and allowing no measurements, the edges being rounded off by irregular planes. Cleavage basal easy, forming thin soft plates. Optically biaxial, axial angle 20° to 30°. Double refraction weak, probably positive. In composition near prochlorite, but containing chiefly magnesium instead of ferrous iron. Websky calculates $H_8R_5AlSiO_7$. Cf. anals. 16–19 above. Analysis, Beck, quoted by Websky:

$SiO_2$ 28·20 $Al_2O_3$ 24·56 FeO 5·27 MgO 30·94 $H_2O$ 12·15 = 101·12

Occurs mixed with a chromic spinel (magnochromite (p. 228), also crystallized in cavities in serpentine at Grochau, south of Frankenstein, in Silesia.

**470. CORUNDOPHILITE.** *Shepard* (fr. N. Car.), Am. J. Sc., **12**, 211, 1852; (fr. Chester, Mass.) *id.*, ib., **44**, 112, 1865. Clinochlore (fr. Chester) *J. P. Cooke*, Am. J. Sc., **44**, 206, 1867.
Amesite *C. U. Shepard;* Pisani, C. R., **83**, 166, 1876.

Monoclinic, Dx. In six-sided or twelve-sided tables or low prisms. Twins, according to the mica law, proved optically.

Cleavage: basal, eminent. Laminæ somewhat more brittle than those of clinochlore. Percussion- and pressure-figures as with clinochlore. The former show planes of parting in the zone *bc* inclined 64° to *c* (089)?, and in the zone *cm* inclined at the angles 71° (223), 75° (445), 37° ($\bar{1}16$), 62° ($\bar{2}25$). Etching-figures monosymmetric in form. H. = 2·5. G. = 2·90, Chester, Brush. Luster of cleavage surface somewhat pearly. Color olive-green, leek-green, grayish green. Transparent to nearly opaque. Laminæ flexible, somewhat elastic.

Optically +. Ax. pl. ‖ *b*. Bx somewhat oblique to *c*. Dispersion $\rho < v$. Axial angle rather large.

$Ac = 56°$ $Bc = 24°$ $2E = 80°$ $[\beta = 1·583]$ $\therefore$ $2V = 46° 40'$ $\mathfrak{c}\,c = 8° 20'$
Also 64° 59′ and 68° at 200° Dx. 32°, 45°, 71½°, 73½° Cooke

**Comp.**—As interpreted by Tschermak, a molecular mixture of $H_4Mg_3Si_2O_9$ and $H_4Mg_2Al_2SiO_9$ in the ratio of 1 : 4 giving the empirical formula $H_{20}Mg_{11}Al_8Si_6O_{45}$, which requires: Silica 23·9, alumina 27·1, iron protoxide 17·5, magnesia 19·5, water 12·0 = 100. Here Fe : Mg = 1 : 2.

**Anal.**—1, Eaton, quoted by Shepard, Am. J. Sc., **46**, 257, 1868. 2, Pisani, ibid. 3, Obermayer, quoted by Tschermak, l. c.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|

**Obs.**—Occurs with corundum or emery; its low percentage of silica accords with this association. The species was instituted on a chlorite found with the corundum of Asheville, N. C., whence the name, from corundum, and *φίλος, friend.* The above description is from specimens occurring abundantly, and sometimes in large and small crystals, at the emery mine of Chester, Mass., which Shepard has referred to corundophilite; the chlorite occurring with the corundum of North Carolina is higher in silica and is classed with prochlorite (Genth), though containing relatively but little iron, cf. anals. 17–20, p. 654.

AMESITE *C. U. Shepard*, Pisani, C. R., **83**, 166, 1876.
In hexagonal plates, foliated, resembling the green talc from the Tyrol. H. = 2·5–3. G. = 2·71. Color apple-green. Luster pearly on cleavage face. Optically +, sensibly uniaxial. Composition approximating to $H_4(Mg,Fe)_2Al_2SiO_9$.
Anal.—Pisani, l. c.

$SiO_2$ 21·4 $Al_2O_3$ 32·3 FeO 15·8 MgO 19·9 $H_2O$ 10·9 = 100·3

Occurs with diaspore at Chester, Mass.

**471. DAPHNITE.** *Tschermak*, Ber. Ak. Wien, **100** (1), 38, 1891. Monoclinic. In small spherical or botryoidal aggregates showing a concentric and at the same time radiate-foliated structure.

Cleavage: basal, perfect. Laminæ somewhat flexible. Luster pearly. Color dark green; though the basal plane olive-green, normal to this direction yellow. Streak green. Optically —, nearly uniaxial.

**Comp.**—According to Tschermak, $H_{56}Fe_{27}Al_{20}Si_{18}O_{121}$. Cf. p. 644.

**Anal.**—R. Zeynek.

| G. | $SiO_2$ | $Al_2O_3$ | FeO | MnO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ | |

**Pyr., etc.**—B.B. becomes black, but does not exfoliate and fuses easily to a steel-gray bead. Easily decomposed by warm hydrochloric acid with the separation of flocculent silica.

**Obs.**—Observed on a specimen from Penzance, Cornwall, obtained in 1840; it occurs as an incrustation on quartz and arsenopyrite.

Named from Daphne, *bay tree*, in allusion to the form.

METACHLORITE. *List*, Zs. G. Ges., **4**, 634, 1852. Foliated columnar, like chlorite, vitreous to pearly in luster, color dull leek-green. H. = 2·5. Anal.—1, List, l. c. 2, Zeynek, quoted by Tschermak.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ | |

B.B. fuses on the edges to a dark enamel. Gelatinizes in the cold with hydrochloric acid. Forms small veins in a green rock at Büchenberg near Elbingerode, in the Harz.

KLEMENTITE *Tschermak*, Ber. Ak. Wien, **100** (1), 40, 1891.

In thin scales in quartz veins at Vielsalm in Belgium. Probably monoclinic. G. = 2·835. Color dark olive-green. Optically +. Biaxial, axial angle small, Tschermak.

Anal.—C. Klement, Bull. Mus. Belg., **5**, 162, 1888.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|

B.B. exfoliates and fuses to a dark glass. In powder partially decomposed by hydrochloric acid with the separation of flocculent silica. Named after Dr. C. Klement of Brussels.

---

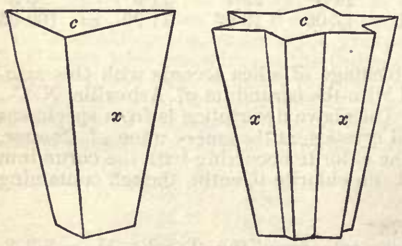
**472. CRONSTEDTITE.** Cronstedtit *Steinmann*, Schw. J., **32**, 69, 1821. Chloromelan *Breith.*, Char., 33, 184, 1823. Sideroschisolite *Wernekink*, Pogg., **1**, 387, 1824.

Rhombohedral; hemimorphic. Axis $\dot{c} = 3·2559$; $0001 \wedge 10\bar{1}1 = 75° \ 6\frac{1}{3}'$ Zepharovich[1].

**Forms:** *c* (0001, *O*); *r* ($10\bar{1}1$, 1), *x* ($20\bar{2}1$, 2); *y* ($30\bar{3}1$, 3).

Angles: $cr = 75° \ 6'$, $cx = 82° \ 25\frac{1}{2}'$, $cy = {}^*84° \ 56'$.

Twins: tw. ax. $\dot{c}$, united symmetrically by a prismatic face or interpenetrating and forming a six-rayed base. Occurs in hexagonal pyramids, tapering toward one extremity, or adhering laterally, and vertically striated; also in fibrous diverging groups, cylindroidal and reniform; also amorphous.



Příbram, Zeph.

Cleavage: basal, highly perfect. Not brittle. Thin laminæ elastic. H. = 3·5. G. = 3·34–3·35. Luster brilliantly vitreous. Color coal-black to brownish black; by transmitted light in thin scales emerald-green; also on the edges brown or brownish yellow. Streak dark olive-green. Nearly opaque. Optically —; uniaxial.

**Comp.**—Perhaps $H_8\overset{II}{Fe}_4\overset{III}{Fe}_4Si_3O_{20} = 4FeO.2Fe_2O_3.3SiO_2.4H_2O$ = Silica 20·9, iron sesquioxide 37·2, iron protoxide 33·5, water 8·4 = 100. Magnesium may be present in small amount.

Rg. gives $3FeO.Fe_2O_3.2SiO_2.3H_2O$ = Silica 21·8, iron sesquioxide 29·1, iron protoxide 39·3, water 9·8 = 100.

**Anal.**—1, E. Ludwig, quoted by Tschermak, Ber. Ak. Wien, **100** (1), 1891. 2, Janovsky, Ber. Ch. Ges., **8**, 939, 1875. 3, Rosam, Vrba, Ber. Ak. Böhm., p. 13, Jan. 15, 1886. 4, Maskelyne and Flight, Ber. Ch. Ges., **3**, 938, 1870.

|---|---|---|---|---|---|---|---|---|
| 1. Přibram | | $\frac{2}{2}$ 22·21 | 37·49 | 25·28 | 1·20 | 5·23 | 8·27 | = 99·68 |
| 2. " | G. = 3·351 | 21·30 | 32·34 | 29·23 | 1·25 | 4·51 | 11·90 | = 100·53 |
| 3. Kuttenberg | G. = 3·445 | 17·34 | 43·05 | 30·27 | 0·16 | — | [9·18] | = 100 |
| 4. Cornwall | | 18·55 | 32·75 | 38·57 | — | — | 10·13 | = 100 |

An analysis by Field (Phil. Mag., **5**, 52, 1878) of a dark green compact mineral accompanying the Cornwall cronstedtite gave:

$SiO_2$ 31·72 $Fe_2O_3$ 18·51 FeO 39·46 $H_2O$ 11·02 = 100·71

Sp. grav. = 3. The formula $3FeO.Fe_2O_3.3SiO_2.3H_2O$ is deduced.

**Pyr., etc.**—B.B. froths and fuses on the edges, yielding in R.F. a magnetic gray or black globule. With borax gives reactions for iron and manganese. Gelatinizes in concentrated hydrocloric acid.

**Obs.**—Accompanies limonite and calcite in veins containing silver ores at Přibram in Bohemia, and also at Kuttenberg; also at Wheal Maudlin and in Cornwall, in diverging groups. In Brazil at Conghonas do Campo (*sideroschisolite*).

Named after the Swedish mineralogist and chemist, A. Fr. Cronstedt.

**Ref.**—[1]Brazil, Ber. Ak. Wien, **71** (1), 276, 1875. Maskelyne (J. Ch. Soc., Jan. 1871) gives for Cornwall crystals *cy* = 85° 12′; exact measurements are impossible. Cf. also Vrba, Ber. Böhm. Ges., p. 13, Jan. 15, 1886. The doubtful scalenohedron $\frac{1}{4}^{\frac{9}{2}}$ ($11 \cdot 7 \cdot \bar{18} \cdot 16$) is added by Zepharovich.

**473. THURINGITE.** Thuringit *Breith.*, Char., 95, 1832. Owenite *Genth*, Am. J. Sc., **16**, 167, 1853.

Massive; an aggregation of minute scales; compact.

Cleavage of scales distinct in one direction. Fracture subconchoidal. Very tough. Feel of powder greasy. H. = 2·5. G. = 3·15–3·19; 3·118 Böttcher. Luster of scales pearly; of mass glistening or dull. Color olive-green to pistachio-green. Streak paler. Optically —. Uniaxial to distinctly biaxial.

**Comp.**—$H_{18}Fe_8(Al,Fe)_8Si_6O_{41} = 8FeO.4(Al,Fe)_2O_3.6SiO_2.9H_2O$ = Silica 22·8, alumina 17·2, iron sesquioxide 13·5, iron protoxide 36·3, water 10·2 = 100.

**Anal.**—1, Rg., Min. Ch., 851, 1860. 2, J. L. Smith, Am. J. Sc., **18**, 376, 1854. 3, Keyser, ibid., p. 411. 4, Gintl, quoted by Zepharovich, Zs. Kr., **1**, 372, 1877. 5, Genth, l. c. 6, 7, Smith, l. c. 8, F. L. Sperry, Am. J. Sc., **32**, 307, 1886.

**Pyr., etc.**—In the closed tube yields water. B.B. fuses at 3 to an iron-black magnetic globule. With the fluxes reacts for iron. Gelatinizes with hydrochloric acid.

**Obs.**—Thuringite is from Reichmannsdorf and Schmiedeberg, near Saalfeld, in Thuringia (cf. Loretz, Zs. Kr., **13**, 52, 1887); at Zirm See in Carinthia (Zeph., l. c.); Hot Springs, Arkansas; from the metamorphic rocks on the Potomac, near Harper's Ferry (owenite); forms the matrix (anal. 8) enclosing garnet crystals altered to a chlorite near aphrosiderite (p. 660) in the Lake Superior iron region; at French Creek mines, Chester Co., Penn., the chalcopyrite and pyrite crystals are embedded in a compact mineral which Penfield suggests is probably allied to thuringite

*Owenite* was named after the geologist, Dr. D. D. Owen.

**Chamosite.** Mine de fer oxydé en grains agglutinés *Gueymard*, J. Mines, **35**, 29, 1814; Chamoisite *Berthier*, Ann. Mines, **5**, 393, 1820. Chamosite. Minerai de fer en grains *Berthier*, Ann. Ch. Phys., **35**, 258, 1827. Berthierine *Beud.*, Tr., 128, 1832. Bavalite *Huot*, Min., 290, 1841.

*Chamosite*, as originally described, occurs compact or oölitic, with H. about 3; G. = 3–3·4; color greenish gray to black; streak lighter; opaque; feebly attracted by a magnet. *Berthierine* is similar in structure, has H. = 2·5; color bluish gray, blackish, or greenish black; streak dark greenish gray; and strongly attracted by the magnet. Anal.—1, Berthier, l. c. 2, id., Ann, Ch. Phys., **35**, 258, 1827:

| | | | | | | |
|---|---|---|---|---|---|---|
| 1. *Chamosite* | $SiO_2$ 14·3 | $Al_2O_3$ 7·8 | FeO 60·5 | $H_2O$ 17·4 | = | 100 |
| 2. *Berthierine* | 12·4 | 7·8 | 74·7 | 5·1 | = | 100 |

Chamosite fuses easily, and also gelatinizes. Berthierine fuses with difficulty to a black magnetic globule, and gelatinizes. The latter is mixed with 50 p. c. or more of siderite and calcite; Berthier found 40·3 of the former in the material he examined.

Chamosite forms thick beds of rather limited extent in a limestone containing ammonites, at Chamoson, near St. Maurice, in the Valais; and a similar substance is reported from Mettenberg in the Bernese Oberland; Banwald in the Vosges; in the Windgälle; with iron carbonate and titanic iron at Schmiedefeld in the Thüringerwald; in Bohemia, from the oölitic iron ore of Chrustenic in dark bluish gray elliptical grains. *Berthierine* constitutes a valuable bed of iron ore at Hayanges, Dept. of Moselle, and also occurs in the ores of Champagne, Bourgogne, Lorraine.

The chloritic mineral associated with the iron ore of Chamoson has been investigated by Boricky, Loretz, and Schmidt and shown to have a composition approximating to thuringite. Berthier's results above are unreliable as giving the composition of the silicate.

Anal.—1, Boricky, as quoted by Schmidt, after deducting 5·5 p. c. Ca,Fe carbonate. 2, C. Schmidt, Zs. Kr., **11**, 601, 1886; also recalculated. 3, Loretz, Zs. Kr., **13**, 52, 1887.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|
| 1. *Chamosite* | 25·60 | 18·72 | — | 42·31 | 2·13 | 11·24 | = | 100 |
| 2. | 25·23 | 19·97 | — | 37·51 | 4·39 | 12·90 | = | 100 |
| 3. Schmiedefeld | 27·29 | 17·13 | 4·06 | 39·42 | — | 13·10 | = | 100 |

An oölitic mineral, apparently near chamoisite, described by Pouillon Boblaye (Mem. Mus., 15), has been called *Bavalite*. It has H. about 4; G. = 3·99 Delesse; color greenish black, bluish, or grayish; powder greenish gray or black, to reddish brown; and B.B. fusible with difficulty to a black magnetic scoria. Forms beds in old schistose rocks in different parts of Brittany, especially in the forest of Lorges, a locality that supplies furnaces at Pas near Quintin, in the vicinity of St. Brieuc, Dept. Côtes-du-Nord; also at the Chapel St. Oudon, near Segré, Dept. Maine-et-Loire; and elsewhere. Huot and others derive the name *bavalite* from Bavalon, a locality of it; but Des Cloizeaux says no such place exists in Brittany; but that a depression in the region where it is explored is called the *bas vallon*—an absurd origin for a name. See 5th Ed., p. 796, for analyses.

**474. STILPNOMELANE.** *Glocker*, Zs. f. Min., Jan., 1828, Handb., 572, 1831. Chalcodite *Shep.*, Rep. Am. Assoc., **6**, 232, 1851.

Foliated plates, sometimes hexagonal, sometimes radiated. Also fibrous, or as a velvety coating even or tufted.

Cleavage easy in one direction. H. = 3·4, when in solid plates. G. = 2·769 Breith.; 2·96, chalcodite, Genth. Luster of cleavage surface between pearly and vitreous, sometimes submetallic or brass-like. Color black, greenish black, yellowish bronze, and greenish bronze.

**Var.**—1. *Ordinary*, in plates or massive. Glocker gives G. = 3–3·4.

2. *Chalcodite*, in velvety coatings of brass-like or submetallic luster, consisting of minute flexible scales.

**Comp.**—Uncertain, perhaps (Brush, Rg.) $2(Fe,Mg)O.(Fe,Al)_2O_3.5SiO_2.3H_2O$.

Genth calculates for his analysis $8(Fe,Mg)O.(Fe,Al)_2O_3.10SiO_2.6H_2O$.

**Anal.**—1, Rg., Pogg., **43**, 127, 1838, Min. Ch., 880, 1860. 2, Siegert, Rg., Min. Ch., 880, 1860. 3, L. J. Igelström, J. pr. Ch., **81**, 396, 1860. 4, G. J. Brush, Am. J. Sc., **25**, 198, 1858. 5, Genth, Am. Phil. Soc., **23**, 44, 1885.

| 4. ***Chalcodite*** | 2·76 | $\frac{2}{2}$ 45·29 | 3·62 | 20·47 | 16·47 | 4·56 | 0·28 | *tr.* | 9·22 | = | 99·91 |
| 5. " | 2·957 | 44·75 | 4·36 | 4·99 | 30·34 | 5·47 | — | — | 9·18 | = | 99·09 |

Brögger refers here the mineral which in the form of inclusions gives the abnormal composition upon which the supposed variety of natrolite from the Brevik region called iron-natrolite (Eisennatrolith) has been based; cf. p. 602. Its composition could not be definitely settled. Zs. Kr., **16**, 626, 1890.

**Pyr.**, etc.—Yields much water. B.B. fuses easily to a black, shining, magnetic globule. With the fluxes gives the reactions for iron. Chalcodite is completely decomposed by hydrochloric acid.

**Obs.**—Stilpnomelane occurs at Obergrund and elsewhere in Silesia, with calcite and quartz, sometimes intermixed with pyrite and magnetite. Also in Moravia, near Brokersdorf; near Sternberg, in a bed of limonite, in a clay slate, probably of the Devonian age, and often associated with chlorite, magnetite, and calcite; at Frederic mine near Weilburg, Nassau, in a bed of iron ore; at Pen Mine, Nordmark, Sweden, radiated foliated with actinolite, in veins sometimes 4 inches thick.

*Chalcodite* occurs at the Sterling Iron mine, in Antwerp, Jefferson Co., N. Y., coating hematite and calcite, and sometimes constituting pseudomorphs (anal. 5), having the form of hollow rectangular tables; the yellow variety resembles in color mosaic gold.

Named *Stilpnomelane* from στιλπνός, *shining*, and μέλας, *black;* and *Chalcodite* from χαλκός, *brass* or *bronze*. Melanglimmer *Germ.* includes this species, Cronstedtite, etc.

**475. STRIGOVITE.** *Becker & Websky*, Jb. Min., 236, 1869. *Websky*, Zs. G. Ges., **25**, 388, 1873.

In minute crystals, showing hexagonal prisms under the microscope; sometimes in balls of aggregated crystals.

H. = 1. G. = 3·144. Color dark green (on alteration changing to brown). Streak green to grayish green. Optically uniaxial or nearly so.

**Comp.**—$H_4Fe_2(Al,Fe)_2Si_2O_{11} = 2FeO.(Fe,Al)_2O_3.2SiO_2.2H_2O$ (at 100°), or with $3H_2O$ (air-dried).

**Anal.**—1, Becker, l. c. 2, Websky, l. c., 1869. 3, Websky (and Poleck), l. c., 1873 (at 100°).

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | | 32 62 | 16·66 | 16·04 | 16·74 | — | 3·16 | 2·02 | 12·37 | = | 99·61 |

**Pyr.**, etc.—Easily decomposed by acid with the separation of silica in powder. In closed tube gives off water. B.B. fuses with difficulty to a black glass without coloring the flame.

**Obs.**—Occurs as a fine coating over the minerals in druses or cavities in the granite west and northwest of Striegau in Silesia.

**476. DIABANTITE.** Diabantachronnyn, *Liebe*, Jb. Min., 1, 1870. Diabantite *G. W. Hawes*, Am. J. Sc., **9**, 454, 1875.

Monoclinic? Massive, compact, fibrous or with a foliated, radiated, and concentric structure.

Cleavage: basal, perfect. H. = 2–2·5. G. = 2·79–2·93. Color dark green to greenish black. Strongly pleochroic.

**Comp.**—$H_{18}(Fe,Mg)_{12}Al_4Si_9O_{45}$ or $12(Fe,Mg)O.2Al_2O_3.9SiO_3.9H_2O$ = Silica 34.2, alumina 12·9, iron protoxide 27·4, magnesia 15·2, water 10·3 = 100.

**Anal.**—1–5, Liebe, l. c. 6, 7, Hawes, l. c.

**Pyr.**—Fuses easily on the edges, forming a dark gray glass somewhat magnetic. Dissolves in hydrochloric acid, leaving a skeleton of silica.

Occurs in the diabase of Voigtland and Frankenwald, and contributes to the green color of the rock. It is found in seams and clefts, sometimes in amygdules and lining cavities in the rock. In some occurrences of diabase it forms the chief binding or cementing material, and is apparently a product of the alteration of the augitic constituent of the diabase.

A similar mineral occurs filling amygdaloidal cavities in the diabase of the Farmington Hills, Conn., and at other points in the same region, as at Turner's Falls, Mass., and elsewhere.

The center cavities are often occupied by calcite, and this and the associated prehnite are often impregnated by it; the diabantite was thus the first product of the decomposition of the diabase (Emerson).

The diabantite is sometimes altered by hydration and oxidation of the iron, forming masses of a straw-, gold-, or bronze-yellow. It then becomes a diabantite-vermiculite, as it is called by Emerson, Am. J. Sc., **24**, 198–201, 1882.

**477. APHROSIDERITE.** *Sandberger*, Ueb. Geol. Nassau, 97, 1847.

Massive; in fine scales, hexagonal in form.

Soft. G. = 2·8–3·0. Color dark olive-green. Transparent to translucent.

**Comp.**—Perhaps (Websky) $H_{10}Fe_6(Fe,Al)_4Si_4O_{26}$.

**Anal.**—1, Sandberger, l. c. 2, Igelström, J. pr. Ch., **84**, 480, 1861. 3, Erlenmeyer, JB. Ch., 773, 1860. 4, Hauer, Jb. G. Reichs., **4**, 79, 1854. 5, Nies, Jb. [a] Incl. MnO 0·20.

Analyses 8–10, by Penfield & F. L. Sperry, are of a chlorite forming the coating of almandite garnets (anal. 6, 7, p. 441) and derived from their alteration. Color of 8, 9, dark green; 10, light green, optically uniaxial. Anal. 11, by Niedzwiedzki, is of a similar chlorite, forming a coating about a like garnet from the Saualpe, Carinthia; magnetite may be present in the material analyzed.

**Obs.**—Aphrosiderite occurs at Weilburg, Nassau, at the Gelegenheit mine. A similar mineral, but more magnesian, has been found in gneiss at Guistberg in Wermland; in hematite at Bouscheuer near Muttershausen, Nassau; at Bulduinstein on the Lahr; and in mica schist with hematite at several places in Upper Styria, consisting of microscopic scales of a clear green color.

**478. DELESSITE.** Chlorite ferrugineuse *Delesse*. Ann. Mines, **12**, 195, 1847, and **16**, 520, 1849. Delessite *Naum.*, Min., 1850. Eisenchlorit. Subdelessit *Weiss*, Zs. G. Ges., **31**, 801, 1879

Massive, with a short fibrous or scaly feathery texture, often radiated.

H. = 2·5. G. = 2·89. Color olive-green to blackish green. Powder gray or green.

**Comp.**—Perhaps (Groth) $H_{10}(Mg,Fe)_4(Al,Fe)_4Si_4O_{23}$.

**Anal.**—1–3, Delesse, l. c. 4–8, Heddle, Trans. R. Soc. Edinb , **29**, 81, 1879. 9, Weiss, l. c.

[a] Loss at 100°· 4, 5·70 p. c; 5, 6·30; 6, 4·68; 7, 3·39; 8, 2·77. [b] Incl. 0·31 MnO.

**Pyr., etc.**—In a matrass yields water and becomes brown. B.B. fuses with difficulty on the edges. Easily soluble in acids, affording a deposit of silica.

**Obs.**—The original delessite occurs coating or filling the cavities of amygdaloid, or amygdaloidal porphyry, at Oberstein, Zwickau, La Grève near Mielen. Similar minerals occur at various points in Scotland, anals. 4–8; also in Nova Scotia (How, Phil. Mag., **37**, 267, 1869).

Named after Delesse, of Paris.

*Subdelessite* (anal. 10) is a blackish green chloritic mineral, filling cavities in eruptive rocks in the Thüringer Wald.

### 479. RUMPFITE. *G. Firtsch,* Ber. Ak. Wien, **99** (1), 417, 1890.

Massive; granular, consisting of very fine scales from 0·05–0·15 in diameter and 1 mm. in length. Form of scales hexagonal, united in vermicular shapes resembling some kinds of clinochlore.

Cleavage: basal, perfect. H. = 1·5. G. = 2·675. Color greenish white. Translucent on the edges. Optically uniaxial or nearly so; sometimes 2E = 10°.

**Comp.**—A basic silicate of aluminium and magnesium; Firtsch calculates the formula: $H_{28}Mg_7Al_{16}Si_{10}O_{65}$ or $7MgO.8Al_2O_3.10SiO_2.14H_2O$.

**Anal.**—Firtsch, l. c.

$SiO_2$ 30·75 $Al_2O_3$ 41·66 FeO 1·61 MgO 12·09 CaO 0·89 $H_2O$ 13·12 = 100·12

The loss of water was as follows:

| 150° | 200°–360° | red ht. (600°) | ign. (Bunsen burner.) | ign. (blast lamp). |
|---|---|---|---|---|
| $\frac{2}{2}$ 0·16 | 0 | 8·73 | 12·51 | 12·79 |

**Pyr., etc.**—B.B. infusible, but becomes brown. Not decomposed by acids, but after ignition the iron compound is dissolved, the rest not decomposed.

**Obs.**—Occurs with talc in crevices in the magnesium carbonate rock (pinolite, p. 274) near St. Michael in Upper Styria.

Named for Professor Johann Rumpf of Graz.

---

## The following are other chloritic minerals, more or less imperfectly defined.

TALC-CHLORITE OF TRAVERSELLA occurs in large hexagonal plates regularly grouped, and presents, according to Des Cloizeaux, the optical characters of clinochlore. The plates are twins, consisting of six triangular sections; at center they are translucent and blackish green, and optically −, and exteriorly clear green and transparent, and optically +. Marignac regards it as between talc and chlorite. He obtained, anal. 1–3, Ann. Ch. Phys., **14**, 60, 1845. 4, Heddle, Trans. R. Soc. Edinb., **29**, 78, 1879.

| | $SiO_2$ | $Al_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. Traversella | 38·45 | 11·75 | 12·82 | — | 28·19 | — | 8·49 | = 99·70 |
| 2. " | 39·81 | 12·56 | 11·10 | — | 28·41 | — | 7·79 | = 99·67 |
| 3. " | 41·34 | 11·42 | 10·09 | — | 29·67 | — | 7·66 | = 100·18 |
| 4. Hillswick | 39·81 | 11·43 | 7·97 | 0·26 | 25·65 | 2·80 | 7·91 | $Na_2O$ 3·15. KO [1·20 = 100·19$_2$ |

It may be ripidolite impure from mixture with talc, which view would account for the high percentage of silica. Occurs at Traversella, Piedmont, with magnetite and ripidolite; also (anal. 4) a similar mineral at Hillswick in Shetland.

At Traversella there is still another *talc-chlorite,* soft and of a silvery-white luster, having a single optical axis, or two very slightly divergent; the hexagonal plates are opaque at center and transparent toward the borders. It affords much water in a matrass, and fuses with difficulty on the edges to a white enamel. This may be identical with the leuchtenbergite, noted by Tschermak from Traversella.

EPICHLORITE *Rammelsberg,* Pogg., **77**, 237, 1849.

Fibrous or columnar, between schiller spar and chlorite in its characters. H. = 2–2·5; G. = 2·76; color dull leek-green; streak white to greenish; luster greasy; in thin columns translucent and of a bottle-green color. Anal.—1, Rg., l. c. 2, Liebe, Jb. Min., 17, 1870.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | | 40·88 | 10·96 | 8·72 | 8·96 | 20·00 | 0·68 | 10·18 | = 100·38 |
| 2. | G. = 2·79 | 41·52 | 8·60 | — | 19·26 | 19·78 | — | 10·05 | = 99·21 |

B.B. fuses only in thin fibers with difficulty. With the fluxes reaction for silica and iron. Forms veins in a rock resembling serpentine near Harzburg. Named in allusion to its being near chlorite in characters.

Liebe's mineral (anal. 2) is the coloring mineral in the black titanic-iron diabase of the Voigtland and Frankenwald. He regards it as containing only ferrous iron, and argues the same for the mineral from the Harz.

EURALITE *F. J. Wiik*, Jb. Min., 357, 1869. A chloritic mineral occurring in seams in clefts of hyperyte in the parish of Eura, Finland. It is apparently amorphous, but breaks under the hammer into prismatic fragments. H. = 2·5. G. = 2·62. Color dark green to black. B.B. fuses easily to a magnetic globule. Soluble in hydrochloric acid. Analysis, Wiik:

$SiO_2$ 33·68 $Al_2O_3$ 12·15 $Fe_2O_3$ 6·80 FeO 15·66 MgO 17·92 CaO 1·34 $H_2O$ 11·49 = 99·04

Apparently related to diabantite, p. 659.

EPIPHANITE. Epifanit *Igelström*, Öfv. Ak. Stockh., **25**, 32, 1868. A chlorite-like mineral from Tvärån in Wermland. Sweden. Analysis, Igelström:

$SiO_2$ 37·11 $Al_2O_3$ 21·13 FeO 20·00 MgO 14·03 $H_2O$ 7·83 MnO *tr.* = 100·10

CHLOROPHÆITE *Macculloch*, Western Isles, 1, 504, 1825.

Granular massive, embedded, or as a coating in geodes, fissures, or amygdaloidal cavities. Cleavage in two directions. H. = 1·5–2. G. = 2·02, Macculloch; 2·28 Heddle. Luster sub-resinous, rather dull. Color dark green, olive-green, changing rapidly to dark brown or black on exposure. In composition somewhat near delessite; cf. also hisingerite. Anal.—1, 2, Heddle, Trans. R. Soc. Edinb., **29**, 84, 1879.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Scuir Mohr | | 36·00 | — | 22·80 | 2·46 | 0·50 | 9·50 | 2·52 | 26·46 | alk. *tr.* = 100·24 |
| 2. Giant's Causeway | 2·278 | 35·99 | 10·49 | 11·89 | 1·63 | 0·08 | 10·52 | 5·15 | 23·20 | alk. 1·10 = 100·04 |

$H_2O$ at 100°: in 1, 19·23; in 2, 14·16.

From the Western Isles of Scotland. at Scuir Mohr in the island of Rum, and from Fifeshire, occurring in amygdaloid; also from the Färöer. Reported also as incrusting chalcedony in Antrim, and in small botryoidal groups in the amygdaloid at Down Hill. But the chemical identity of the original chlorophæite of Macculloch from Scuir Mohr with that of the Färöer or the other localities has not yet been ascertained. Named from χλωρός, *green*, and φαιός, *brown*.

HULLITE *E. T. Hardman*, Proc. Roy. Irish Acad., 3, 161, 1878.

Massive. H. = 2. Color velvet-black. Luster waxy but dull. Near delessite and chlorophæite, but not a homogeneous mineral (cf. Lcx., Bull. Soc. Min., **8**, 432, 1885). Anal.—1, Hardman, l. c. 2, Heddle, Trans. R. Soc. Edinb., **29**, 89, 1879.

$H_2O$ lost at 100° in 2, 8·04 p. c.

Occurs filling and coating vesicular cavities in the basalt of Carnmoney Hill, near Belfast, Ireland. A similar mineral occurs in the basalt at Kinkell, in Fifeshire, Scotland.

MELANOLITE *Wurtz*, Dana, Min., 679. 1850. It is black, opaque, with streak dark olive-green; H. = 2; G. = 2·69. Surface of the mineral often striated, or with an imperfectly columnar aspect. Analysis.—H. Wurtz, excluding 12·77 $CaCO_3$:

$SiO_2$ 35·24 $Al_2O_3$ 4·48 $Fe_2O_3$ 23·13 FeO 25·09 $Na_2O$ 1·85 $H_2O$ 10·21 = 100.

From Milk-Row quarry, near Somerville, Mass., incrusting the sides of a fissure. Cf. hisingerite, p. .

EKMANNITE *L. J. Igelström*, Öfv. Ak. Stockh., **22**, 607, 1865, B. H. Ztg., **26**, 21, 1867.

Foliated. chlorite-like. Also foliated columnar and asbestiform, radiated; also granular massive, consisting of minute scales. Hardness and luster as in common kinds of chlorite. Color grass-green, leek-green, grayish white; also black.

Anal.—1–6, Igelström :

[a] With perhaps some alumina.

On heating yields water, becomes black, submetallic, and after ignition strongly magnetic. B.B. fuses to a black slag. Soluble in hydrochloric acid, with a deposition of silica.

From a mine of magnetite at Grythytte, in Sweden, filling cavities in the ore, penetrating it extensively, and constituting nodular masses and beds. Becomes black on exposure, through oxidation. Anal. 4 is of the green interior of a nodule which was black externally. Some of it contains calcium carbonate, and some affords when heated a bituminous odor. Named after G. Ekman, proprietor of the mine, hence properly *ekmanite*. See p. 1033.

BERLAUITE *A. Schrauf*, Zs. Kr., **6**, 383, 1882. An alteration-product occurring at Krems, Bohemia, at the contact between serpentine and granulyte. Occurs in aggregates of small scales of a dark grass-green color. Axial angle nearly zero. On ignition does not change form, but becomes light yellowish brown with pearly luster resembling mica. Analysis, 1*a*, air-dried; 1*b*, dried at 100°.

| 34·38 | 12·69 | 6·33 | 3·71 | 23·79 | 2·59 | 16·79 | $Cr_2O_3$,MnO,$K_2O$ *tr.* = 100·28 |
| 37·25 | 13·75 | 6·86 | 4·02 | 25·77 | 2·81 | 9·82 | |

Schrauf (ibid.) uses the name *parachlorite* for chlorites whose composition he refers to the orthosilicate formula $m(Al_4Si_3O_{12}).n(R_2SiO_4).pH_2O$; while he applies the name *protochlorite* to those which he explains as $m(Al_2SiO_5).n(R_2SiO_4).p(H_2O)$.

STEATARGILLITE *E. E. Schmid*, Ber. Ges. Jena, **14**, July 9, 1880. A doubtful substance, filling, with quartz and ferrite, small amygdaloidal cavities in the porphyritic rocks of the Höllekopf, at Kammerberg, and of the Tragberg, at Langewiesen, near Ilmenau. Massive, earthy. H. = 1·25. G. = 2·29–2·46. Color white to light green. Feel greasy. B.B. fuses to a greenish gray-black specked enamel; yields much water in the tube, becoming black, and giving a bituminous odor. Analyses: 1–3, after deducting 6 p. c. insol. from 1, and 2 p. c. from 3.

[a] In vacuo, at ordinary temperature, 1·91; at 100° 3·90. [b] Do. 4·55, 2·52. [c] Do. 0·70, 7·27.

PATTERSONITE *I. Lea*, Proc. Ac. Philad., 45, 1867. A micaceous mineral from Unionville, Chester Co., Penn. An analysis by Genth (Am. Phil. Soc., **13**, 1873) gave:

| G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $K_2O$ | $Na_2O$ | ign. |
|---|---|---|---|---|---|---|---|---|
| 2·81 | 29·90 | 27·59 | 3·12 | 9·17 | 17·10 | 2·33 | 0·58 | 11·51 = 101·30 |

It is hence near thuringite. An earlier, less accurate, analysis is given by S. P. Sharples Am. J. Sc., **47**, 319, 1869.

A CHLORITE-LIKE mineral from Webster, N. C., in crystals, micaceous in structure, of a dark bluish to brownish green color, afforded Genth, Am. J. Sc., **33**, 200, 1862:

| $SiO_2$ | $Al_2O_3$ | $Cr_2O_3$ | FeO | NiO | MgO | CaO | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| $\frac{2}{3}$ 31·45 | 13·08 | 4·16 | 4·88 | 0·16 | 43·10 | 0·17 | 0·06 | 3·29 = 100·35 |

It is remarkable for the small amount of water and iron, and the large proportion of magnesia; a constitution which may have an explanation in its being a mixture of talc and chlorite. It is associated with talc which Genth found to be nearly anhydrous.

CHLORITE-LIKE MINERAL, from the *Keuper* of Altenburg, *Haushofer*, J. pr. Ch., **99**, 239, 1866. Color dark leek-green. Stated to be B.B. infusible. Analysis gave: $SiO_2$ 29·51, $Al_2O_3$ 11·54, $Fe_2O_3$ 18·26, FeO 25·26, CaO 0·52, $H_2O$ 14·81 = 99 90.

BALTIMORITE. "Baltimorite," so called from Baltimore, afforded Hauer (Jb. G. Reichs., 1853): $SiO_2$ 27·15, $Al_2O_3$ 18·54, CaO 15·08, MgO 26·00, $H_2O$ 13·23 = 100. Hermann found in "Baltimorite" of a bluish color: $SiO_2$ 33·26. $Al_2O_3$ 7·23, $Cr_2O_3$ 4·34, FeO 2·89, MgO 38·56, $H_2O$ 12·44, $CO_2$ 1·30. Thomson, who instituted the species (Phil. Mag., **22**, 193, 1843) found for it the composition essentially of serpentine (see 5th Ed., anal. 77, p. 467). It is a good example of the indefinite mixtures that exist between serpentine and allied minerals.

DUMASITE *Delesse*, Dufr. Min., **3**, 790, 1847, **3**, 286, 1859. A chlorite lining cavities or fissures in certain melaphyres in the Vosges; color green; soft, and somewhat resembling clinochlore.

PRASILITE *T. Thomson*, Phil. Mag., **17**, 416, 1840. A leek-green fibrous mineral, soft as Venetian talc, from Kilpatrick Hills, the fibers loosely cohering, with G. = 2·311. Stated to consist of silica, magnesia, iron sesquioxide, and alumina, with probably soda, and 18 p. c. of water. Analysis not given. Probably a chlorite of some kind.

GRASTITE *J. B. Pearse*, Am. J. Sc., 37, 221, 1864. A chlorite from Texas, Lancaster Co., Penn., with 28·62 p. c. $SiO_2$; probably simply clinochlore, perhaps impure. Named in allusion to the color from *γράστις, grass.* See further 5th Ed., p. 501.

VIRIDITE *Vogelsang*, Zs. G. Ges., 24, 529, 1872. A collective name proposed for all the indeterminate *green* compounds of secondary origin observed in rocks, to be regarded as hydrous silicates of ferrous iron and magnesium. They are generally in scaly or fibrous forms and are often the result of the decomposition of amphibole, pyroxene, chrysolite, etc. The name is also used by Dathe (ib., **26**, p. 10), who discusses its relation to Liebe's diabantachronnyn (diabantite, p. 659) and Sandberger's aphrosiderite (p. 660); but cf. Rosenbusch, Mass. Gesteine, 183, 1886–87. "Viridite," as ordinarily used, probably includes several kinds of chlorite and perhaps also serpentine.

Gümbel has similarly used *chloropite* for the green chloritic constituent of much diabase.

## APPENDIX TO THE MICA DIVISION.—VERMICULITES.

The VERMICULITE GROUP includes a number of micaceous minerals, all hydrated silicates, in part closely related to the chlorites, but varying somewhat widely in composition. They are alteration-products chiefly of the micas, biotite, phlogopite, etc., and retain more or less perfectly the micaceous cleavage, and often show the negative optical character and small axial angle of the original species. Many of them are of a more or less indefinite chemical nature, and the composition varies with that of the original mineral and with the degree of alteration.

The laminæ in general are soft, pliable, and inelastic; the luster pearly or bronze-like, and the color varies from white to yellow and brown. Heated to 100°–110° or dried over sulphuric acid most of the vermiculites lose considerable water, up to 10 p. c., which is probably hygroscopic; at 300° another portion is often given off; and at a red heat a somewhat larger amount is expelled. Connected with the loss of water upon ignition is the common physical character of exfoliation; some of the kinds especially show this to a marked degree, slowly opening out, when heated gradually, into long worm-like threads. This character has given the name to the group, from the Latin *vermiculari, to breed worms.* The name was first given by T. H. Webb, see below.

The composition of the vermiculites has been discussed by Cooke, Proc Am. Acad., **9**, 44, 1874, **10**, 453, 1875. Tschermak, Ber. Ak. Wien, **100** (1), 92 *et seq.*, 1891. who ranks them as chlorites; Clarke & Schneider, Am. J. Sc., **40**, 452, 1890, **42**, 242, 1891. See further beyond.

### 480. JEFFERISITE.

Vermiculite? *G. J. Brush*, Am. J. Sc., **31**, 369, 1861. Jefferisite, *id.*, ib., **41**, 248, 1866. Culsageeite *J. P. Cooke*, Proc. Am. Acad., 48, 1874.

In broad crystals or crystalline plates. Surface of plates often triangularly marked, by the crossing of lines at angles of 60° and 120°.

Cleavage: basal, eminent. Flexible, almost brittle. H. = 1·5. G. = 2·30. Luster pearly on cleavage surface. Color dark yellowish brown and brownish yellow; light yellow by transmitted light; also greenish yellow. Optically biaxial, Dx.

**Comp.**—A hydrated mica, formula (Cooke) approximately $2\overset{II}{R}O.\overset{III}{R}_2O_3.5SiO_2.5H_2O$.

Cooke shows that the oxygen ratio, $\overset{II}{R} + \overset{III}{R} : Si : H = 1 : 2 : 2$, holds nearly true for a number of the vermiculites, as dried at 100°.

Clarke and Schneider deduce the empirical formula $H_{70}\overset{II}{R}_{53}\overset{III}{R}_{42}Si_{57}O_{255} + 82H_2O$; this is interpreted as approximately $\overset{I}{R}_3(AlO_2)MgSiO_4.3H_2O + H_2Mg_2Al_2(SiO_4)_3.3H_2O$, or a mixture in equal ratios of a *hydro-clintonite* and a *hydro-biotite*, both trihydrated, i.e., taking the mineral as air-dried.

**Anal.**—1, Brush, l. c. 2. Koenig, quoted by Genth. 3, Chatard, quoted by Genth, l. c. 4, Clarke & Schneider, Am. J. Sc., 40, 452, 1890. 5, Koenig, ib. 6, Chatard, ibid. 7, Cooke, l. c. 8, Id., Proc. Am. Acad., 454, 1875.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. West Chester | | 37·10 | 17·57 | 10·54 | 1·26 | 19·65 | 13·76 | CaO 0·56, $K_2O$ 0·43 = 100·87 |
| 2. " | | 33·35 | 17·78 | 7·32 | 2·11 | 19·26 | 19·87 | = 99·69 |
| 3. " | | 34·40 | 16·63 | 8·00 | 2·11[a] | 19·30 | 19·03 | = 99·47 |
| 4. " | | 34·20 | 16·58 | 7 41 | 1·13 | 20·41 | 21·14 | = 100·87 |
| *Culsageeite.* | | | | | | | | |
| 5. Culsagee | | 33·93 | 17·38 | 5·42 | 0·52 | 23·43 | 19·17 | NiO 0·35 = 100·18 |
| 6. " | | 33·77 | 17·56 | 5·61 | 0·50[a] | 22·48 | 20·30 | = 100·22 |
| 7. " | | $\frac{3}{3}$ 37·37 | 19·90 | 5·95 | 0·58 | 25·26 | 11·09 | = 100·15 |
| 8. *Pelhamite* | 2·16 | $\frac{3}{3}$ 41·27 | 15·19 | 4·14 | — | 28·25 | 11·32 | = 100·17 |

[a] Koenig's determination.

Anal. 1 and 7 on material dried over sulphuric acid; anal. 2–6 on air-dried material, deducting the hygroscopic moisture, these analyses agree with 1 and 7, as shown by Cooke.

Loss of water for anal. 1 and 4:

| | $H_2SO_4$ | 100° | 220° | red heat | wh. heat |
|---|---|---|---|---|---|
| 1. | 4·19 | 3·74 | 4·17 | 5·85 | |
| | | | 250°–300° | | |
| 4. | 10·56 | | 4·20 | 6·18 | 0·20 |

Clarke and Schneider found that gaseous hydrochloric acid at 383° to 412° after 32 hours removed 3·98 MgO and 1·38 $R_2O_3$. After strong ignition and subsequent digestion in acid for three days, 51·08 p. c. of insoluble residue remained, which gave: $SiO_4$ 45·08, $Al_2O_3$ 22·82, $Fe_2O_3$ 10·01, MgO 21·48 = 99·39.

**Pyr., etc.**—When heated to 300° C. exfoliates very remarkably (like vermiculite, see below); B.B. in forceps after exfoliation becomes pearly-white and opaque, and ultimately fuses to a dark gray mass. With the fluxes reactions for silica and iron. Decomposed by hydrochloric acid.

**Obs.**—Occurs in veins in serpentine at West Chester, Pa. Plates often several inches across. Named after W. W. Jefferis of West Chester, Pa.

*Culsageeite* is from the Culsagee corundum mine, near Franklin, Macon Co., N. Carolina.

*Pelhamite* is from Pelham, Mass., color greenish yellow.

A foliated mineral similarly exfoliating occurs coarse-granular massive, according to R. Pumpelly, in Japan, in the mountains of the peninsula of Kadzusa, S.E. of Yedo.

A "vermiculite-granite" is described by Parke as occurring in Walney Is., N. Lancashire, England, Proc. Yorkshire G. Soc., **4**, 254, 1877.

VERMICULITE *T. H. Webb*, Am. J. Sc., **7**, 55, 1824.

Occurs in small foliated scales, distributed through a steatitic base, and hence scaly-massive. H. = 1–2; G. = 2·756 Crossley; luster somewhat talc-like; color grayish, somewhat brownish. Anal.—Crossley, Dana Min., 3d Ed., 291, 1850.

| $SiO_2$ | $Al_2O_3$ | FeO | MgO | $H_2O$ | |
|---|---|---|---|---|---|
| 35·74 | 16·42 | 10·02[a] | 27·44 | 10·30 | = 99·94 |

[a] The iron is probably mostly present as $Fe_2O_3$, Cooke.

When heated exfoliates remarkably, the scales opening out into long, worm-like threads, made up of the separate folia. Exfoliation commences at 500° to 600° F., and takes place with so much force as often to break the test-tube in which the mineral may be confined. B.B. fuses at 3·5 to a grayish black glass.

Occurs at Milbury, near Worcester, Mass.

KERRITE *Genth*, Am. Phil. Soc., **13**, 396, 1873.

In fine scales, presenting no definite shape under the microscope. Very soft. G. = 2·303 Chatard. Color pale greenish yellow, with tint of brown; luster pearly.

Anal.—1, Chatard, quoted by Genth, l. c. 2, Clarke & Schneider, Am. J. Sc., **40**, 452, 1890.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | (Ni,Co)O | MgO | ign. | |
|---|---|---|---|---|---|---|---|---|
| 1. | $\frac{2}{2}$ 38·29 | 11·41 | 1·95 | 0·32 | 0·25 | 26·40 | 21·25 | = 99·87 |
| 2. | 38·13 | 11·22 | 2·28 | 0·18 | 0·48[a] | 27·39 | 20·47 | = 100·15 |

[a] CoO *tr.*

Anal. 2 on air-dried material. Loss of water as follows:

| $H_2SO_4$ | 105° | 250°–300° | red heat | wh. heat |
|---|---|---|---|---|
| 9·62 | 0·24 | 4·10 | 6·27 | 0·24 |

For a discussion of the composition see Clarke & Schneider, l. c., who show that it is essentially a trihydrated phlogopite, with alkalies replaced by hydrogen; over $H_2SO_4$ it becomes monohydrated.

Exfoliates upon heating, but not to such an extent as jefferisite. B.B. fuses to a white enamel. Decomposed by hydrochloric acid with separation of silica in pearly scales. Found as an apparent result of the alteration of chlorite at the corundum locality, Culsagee mine, near Franklin, Macon Co., N. Carolina. Named from Prof. W. C. Kerr (d. 1885), State Geologist of North Carolina.

LUCASITE *T. M. Chatard*, Am. J. Sc., **32**, 375, 1886.

Foliated, compact, and disseminated; folia small. G. = 2·613. Luster submetallic, bronze-like. Color yellowish brown. Optically biaxial. Axial angle small.

Anal.—Chatard, l c. 1, air-dried material; 2, calculated for dried at 110°.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Cr_2O_3$ | FeO | MnO | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$(rd.ht.) | $H_2O$(110°) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| $\frac{2}{2}$ | 39·81 | 12·99 | 5·29 | 0·54 | 0·11 | 0·05 | 24·83 | 0·14 | 5·76 | 0·20 | 6·98 | 3·78 = 100·48 |
| | 41·17 | 13·43 | 5·47 | 0·56 | 0·11 | 0·05 | 25·68 | 0·14 | 5·96 | 0·21 | 7·22 | — = 100 |

Exfoliates largely upon ignition. Easily decomposed by hydrochloric acid, leaving the silica in pearly scales. Occurs with actinolite at Corundum Hill, Macon Co., N. C. Named for Dr. H. S. Lucas, prominently connected with the development of corundum mines in Massachusetts and N. Carolina.

LENNILITE. Lernilith (wrong orthogr.) *Schrauf*, Zs. Kr., **6**, 350, 1882.

A vermiculite from Lenni, Delaware Co., Penn. Also a similar mineral from the serpentine region of Bohemia at Krems (or Křemže) is included here. The Lenni mineral is in part silver-white (anal. 3), also bronze-brown (anal. 4), and dark green, resembling clinochlore (anal. 5).

Anal.—1, Schrauf, l. c. 2, Gooch, quoted by Cooke, Proc. Am. Acad., 453, 1875. 3–5, Clarke & Schneider, Am. J. Sc., **42**, 245, 1891.

| | | $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Cr_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1*a*. Krems | | 35·83 | — | 12·39 | 2·97 | *tr.* | 2·35 | — | 26·33 | 0·42 | 19·60 = 99·89 |
| 1*b*. " | | 38·88 | — | 13·45 | 3·22 | — | 2·55 | — | 28·57 | 0·45 | 12·75 = 99·87 |

| 5. | 5·21 | 4·99 | 1·60 | 9·88 |

For a discussion of the composition, see Clarke and Schneider, l. c.

HALLITE *Leeds*, Journ. Frank. Inst., **62**, 70, 1871. *J. P. Cooke*, Proc. Am. Ac. Boston, 59, 1874.

Occurs in large rough six-sided prisms with easy micaceous cleavage. Color in some varieties green, in others yellow. G. = 2·40. Exhibits asterism, and shows symmetrically arranged inclusions under the microscope.

Anal.—1, 2, C. E. Munroe, quoted by Cooke, l. c. 3, Clarke and Schneider, Am. J. Sc., **42**, 244, 1891.

| | G. | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | $K_2O$ | $H_2O$ |

[a] Incl. 0·16 NiO.

In anal. 3, $H_2O$ at 105°, 2·64 p. c.; 250°–300°, 1·23; red ht., 10·91.

For a discussion of composition, see Clarke and Schneider, l. c.

Found at East Nottingham, 3 miles south of Oxford, Chester Co., Penn., in nests or pockets in the serpentine formation. Named after Mr. John Hall, of Philadelphia.

PAINTERITE *Jefferis;* Clarke and Schneider, Am. J. Sc., **42**, 247, 1892.

Includes a dull green vermiculite with axial angle of 25°; from the Corundum mine in Newlin township, Chester Co., Penn. Also a golden yellow mineral, strongly exfoliating, found on the farm of James Painter, Middletown, Delaware Co., Penn.

Anal.—1–3, Clarke and Schneider, Am. J. Sc., **42**, 248, 1891.

|---|---|---|---|
| 1. | 1·08 | 0·40 | 12·15 |
| 2. | 1·64 | 1·03 | 15·75 |
| 3. | 1·56 | 0 59 | 16·46 |

On the results of treatment with HCl gas and a discussion of composition, see Clarke and Schneider, l. c., who show that painterite should probably be classed as a chlorite.

PHILADELPHITE *H. C. Lewis*, Proc. Ac. Philad., Dec. 22, 1879.

In contorted and wrinkled plates, with micaceous structure. Laminæ inelastic. H. = 1·5. G. = 2·80. Luster pearly. Color brownish red. Axial angle 31° 20′ to 39° 30′.

Anal.—1, Haines, quoted by Lewis. 2, Lewis, l. c.

| G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |

[a] Incl. 0·06 (Ni,Co)O, 0·08 CuO.

Material for above dried at 100°; hygroscopic water 3·28 in 1, and 3·24 in 2.

B.B. exfoliates largely; on heating (150°–160°) expanded to ten times its volume; a small fragment exfoliating raised 50,000 times its own weight. Slowly dissolved in hydrochloric acid.

From the hornblendic gneiss near Philadelphia on Germantown Avenue near Wayne Station.

PROTOVERMICULITE *G. A. König*, Proc. Ac. Nat. Sc. Philad., 269, 1877.

Micaceous structure. H. = 2. G. = 2·269. Color yellowish silvery to bronze. Optic-axial angle small. From Magnet Cove, Arkansas; a similar hydrobiotite from Henderson Co., N. Carolina, has been examined by Clarke and Schneider.

Anal.—1, Koenig, l. c. 2, 3, Clarke and Schneider, Am. J. Sc., **42**, 242, 1891.

| 2. | 11·23 | 4·55 | 5·41 |
| 3. | 3·20 | 2·52 | 4·80 |

Clarke and Schneider conclude that protovermiculite is essentially a trihydrated hydrophlogopite and hydroclintonite in the ratio of 1 : 1. The Henderson Co. mineral is a biotite about half way transformed into a vermiculite.

VAALITE *Maskelyne* and *Flight*, Q. J. G. Soc., **30**, 409, Nov., 1874.

In hexagonal prisms. Axial angle very small. Bx nearly ⊥ *c*. Color drab, in spots fine blue. Analysis:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | $Na_2O$ | $H_2O$[a] | $CO_2$ | $Cr_2O_3$ |
|---|---|---|---|---|---|---|---|
| 40·83 | 9·80 | 6·84 | 31·34 | 0·67 | 9·72 | *tr.* | *tr.* = 99·20 |

[a] Lost at a low red heat; also from 125°–130°, 1·95 p. c.

Expands on heating on a platinum foil to six times its original size; in powder no expansion at all. Loses no water at 100° C. Occurs in an altered peridotyte from the diamond-diggings, called Du Toit's Pan, S. Africa (cf. p. 5). Named after the Vaal river.

MACONITE *Genth*, Am. Phil. Soc., **13**, 396, 1873.

In irregular scales, resembling a variety of jefferisite. Soft, but slightly harder than kerrite.

G. = 2·827 Chatard. Color dark brown; luster pearly, inclining to sub-metallic. Anal.—Chatard and Genth, l. c.

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | (Ni,Co)O | MgO | $K_2O$ | $Na_2O$ | $Li_2O$ | ign. |

Exfoliates largely on heating, and fuses with difficulty to a brown glass; easily decomposed by hydrochloric acid, with separation of silica in scales.

Contains numerous fragments of corundum, and some microscopic reddish brown crystals which may be titanite. Found, as an apparent result of the alteration of chlorite, at the corundum locality, Culsagee Mine, near Franklin, Macon Co., N. Carolina.

**Dudleyite** *Genth*, Am. Phil. Soc., 13, 404, 1873.

Has the form of margarite, from the alteration of which it has been made. Color soft bronze, or brownish yellow; luster pearly. Anal.—Genth, l. c.

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $Li_2O$ | $Na_2O$ | $K_2O$ | ign. |

Exfoliates slightly on heating, and fuses with difficulty to a brownish yellow blebby mass. Easily decomposed by hydrochloric acid with separation of silica in scales. Found at the Cullakenee Mine, Clay Co., N. Carolina, and in larger quantity with margarite at Dudleyville, Alabama.

**Pyrosclerite.** Pyrosklerit *v. Kobell*, J. pr. Ch., 2, 53, 1834.

Cleavage: basal eminent or micaceous; in a transverse direction at right angles to the former, in traces. H. = 3. G. = 2·74. Luster of cleavage surface weak pearly. Color apple- to emerald-green.

Anal.—1, Kobell, l. c. 2, Leeds, Am. J. Sc., 6, 22, 1873.

[a] $Cr_2O_3$

B.B. fuses at 3·8–4 to a grayish glass. With the fluxes reacts for chromium and iron. Decomposed by hydrochloric acid with gelatinization.

Occurs with chonicrite, constituting seams in serpentine, near Porto Ferrajo, Elba. It is probably derived from some form of pyroxene (diallage), the cleavage of which it retains in part. Named from πῦρ, *fire*, and σκληρός, *hard* (refractory).

A related mineral occurs at the "Magnesia mines" of the Bare Hills, Maryland, in grayish to bronze-yellow folia; optically biaxial. Forms a vertical seam between deweylite on one side and talc on the other. Cf. anal. 2.

For analysis also of another related mineral from St. Marie-aux-Mines, Alsace, see Knop, Jb. Min., 70, 1875.

**Roseite.** A much altered mica found by Dr. Rose in East (or West) Nottingham, Chester Co., Penn. Soft, like talc; luster pearly; color nearly pale brownish yellow. Analysis, quoted by A. J. Moses, Sch. Mines Q., 12, 73, 1891.

$SiO_2$ 35·38 $Al_2O_3$ 30·30 MgO 14·66 $H_2O$ 19·88 = 100·32

---

Some other alteration-products of biotite, allied to the vermiculites (voigtite, etc.), are mentioned on p. 632.

---

**Willcoxite** *Genth*, Am. Phil. Soc., 13, 397, 1873.

In scales white to greenish or grayish white, with pearly luster, resembling talc. Anal.—Koenig, quoted by Genth, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | $Li_2O$ | $Na_2O$ | $K_2O$ | ign. |

B.B. fuses in fine splinters with difficulty to a white enamel, coloring the outer flame yellow. In hydrochloric acid decomposed with difficulty, with separation of silica in scales. Occurs as a coating about a nucleus of corundum, and resulting from its alteration, at Shooting Creek and Cullakenee Mine, Clay Co., No. Carolina.

Named after Col. Joseph Willcox.

## III. Serpentine and Talc Division.

The leading species belonging here, Serpentine and Talc, are closely related to the Chlorite Group of the Mica Division preceding, as noted beyond. Some other magnesium silicates, in part amorphous, are included with them.

| | | |
|---|---|---|
| 481. Serpentine | $H_4Mg_3Si_2O_9$ | Monoclinic |

Metaxite *Breithaupt*, Char., 113, 326, 1832 Baltimorite *Thomson*, Phil. Mag., **22**, 191, 1843. Zermattite *N. Nordenskiöld*, At. Ch. Min. Syst., 132, 1848.

Monoclinic. In distinct crystals, but only as pseudomorphs. Sometimes foliated, folia rarely separable; also delicately fibrous, the fibers often easily separable, and either flexible or brittle. Usually massive, but microscopically finely fibrous and felted, also fine granular to impalpable or cryptocrystalline; slaty. Crystalline in structure but often by compensation nearly isotropic; amorphous.

Cleavage *b* (010), sometimes distinct; also prismatic (50°) in chrysotile (Brauns). Fracture usually conchoidal or splintery. Feel smooth, sometimes greasy. H. = 2·5–4, rarely 5·5. G. = 2·50–2·65; some fibrous varieties 2·2–2·3; retinalite, 2·36–2·55. Luster subresinous to greasy, pearly, earthy; resin-like, or wax-like; usually feeble. Color leek-green, blackish green; oil- and siskin-green; brownish red, brownish yellow; none bright; sometimes nearly white. On exposure, often becoming yellowish gray. Streak white, slightly shining. Translucent to opaque.

Pleochroism feeble. Optically −, perhaps also + in chrysotile. Double refraction weak. Ax. pl. $\parallel a$ (100). Bx $(\mathfrak{a}) \perp b$ (010) the cleavage surface; $\mathfrak{c} \parallel$ elongation of fibers. Biaxial, angle variable, often large: 2E = 16° to 98° Tschermak. 2V = 20° to 90° Lévy-Lcx. Dispersion $\rho > v$.

*Antigorite*, $2E = 27°$, $\beta = 1·574$ Dx.
*Chrysotile* 2V variable, up to 30° Lévy-Lcx.
" Reichenstein $2E = 16° 30'$ Reusch, 24° Hare Amelose $2E = 50°$ Brauns.

Indices:
*Antigorite* $\alpha = 1·560$ $\beta = 1·570$ $\gamma = 1·571$ $\gamma - \alpha = 0·011$ Lévy-Lcx.

Statements in regard to the optical character, axial angle, etc., are somewhat conflicting, cf. Rosenbusch, Lévy-Lcx. *et al.* (ref. p. 674).

Hussak describes a pale green foliated mineral making up the mass of the serpentine of Sprechenstein, Sterzing, Tyrol, which yields folia with basal cleavage; pleochroism rather strong; optically −; Bx ⊥ cleavage; axial angle small (20° Tsch.). Tschermak regards this variety as intermediate between normal serpentine and penninite; chemically it contains 3·8 p. c. $Al_2O_3$, anal. 32.

**Var.**—Many unsustained species have been made out of serpentine, differing in structure (massive, slaty, foliated, fibrous), or, as supposed, in chemical composition; and these now, in part, stand as varieties, along with some others based on variations in texture, etc.

A. In CRYSTALS—PSEUDOMORPHS. The most common have the form of chrysolite. Other kinds are pseudomorphs after pyroxene, amphibole, spinel, chondrodite, garnet, phlogopite, titanite, chromite, etc.

Thus at the Tilly Foster magnetite mine, Brewster, N. Y., serpentine occurs on a large scale both massive and distinctly pseudomorphous, the latter after enstatite, chondrodite, amphibole, clinochlore, biotite, brucite; probably also after calcite, apatite, dolomite; further in forms showing a perfect cubic parting (anal. 12, 13), and assumed to be pseudomorphous after an unknown mineral (periclase?, Tschermak). G. Friedel has examined these cubic forms (Bull. Soc. Min., **14**, 120, 1891) and shows that the serpentine is in part crystalline (opt. −, biaxial, $\gamma - \alpha = 0·005$), in part amorphous, and argues that the pseudo-cubic structure belongs to the serpentine itself and is not due to some other original mineral.

*Bastite* or *Schiller Spar* is enstatite (hypersthene) altered more or less completely to serpentine. See description on p. 351.

B. MASSIVE. 1. *Ordinary massive.* (*a*) *Precious* or *Noble Serpentine* (Edler Serpentin *Germ.*) is of a rich oil-green color, of pale or dark shades, and translucent even when in thick pieces; and (*b*) *Common Serpentine,* when of dark shades of color, and subtranslucent. The former has a hardness of 2·5–3; the latter often of 4 or beyond, owing to impurities.

2. *Resinous. Retinalite.* Massive, having honey-yellow to light oil-green colors, and waxy or resin-like luster and aspect. H. = 3·5; G. = 2·47–2·52, Grenville, Hunt, 2·36–2·38, Calumet Id., Hunt. It much resembles deweylite. It affords, on analysis, 3 p. c. more of water than ordinary serpentine; and the mineral may be a mixture of serpentine and deweylite. *Vorhauserite* is similar, though brown to greenish black in color. H. = 3·5; G. = 2·45. From the Fleimsthal, Tyrol.

3. *Porcellanous; Porcellophite.* The "meerschaum" of Taberg and Sala is a soft earthy serpentine, resembling meerschaum in external appearance (Berlin, Ak. H. Stockh., 1840). This variety is sometimes very soft when first taken out. A variety resembling compact lithomarge occurs at Middletown, Delaware Co., Pa. It has a smooth, porcelain-like fracture; H. = 3·5; G. = 2·48.

4. *Bowenite* (Nephrite *Bowen*). Massive, of very fine granular texture, and much resembles nephrite, and was long so called. It is apple-green or greenish white in color; G. = 2·594–2·787, Bowen; and it has the unusual hardness 5·5–6. From Smithfield, R. I.

A serpentine from New Zealand is referred here by Berwerth (l. c. and anal. 26). It is bright green, translucent; hardness = 5·5–6, on a polished surface; G. = 2·60. Used by the Maoris for objects of ornament and called by them *Tangiwai.*

A similar serpentine is described by C. A. McMahon (Min. Mag., **9**, 187, 1890) as used at Bhera, in the Shahpur district of the Punjab, for the manufacture of various small articles; it is called in Persian *Sang-i-yashm.* H. = 5. G. = 2·59. Color dark greenish gray to pale sea-green mottled with white; also said to be delicate apple-green. Structure finely fibrous, as seen under the microscope and as developed by digestion in sulphuric acid; extinction parallel, the greater axis corresponding with the direction of the fibers (anal. 27). Occurs in place in rock masses in one of the mountain gorges which run from the Safed Koh in the valley of the Kâbul river, Afghanistan.

C. LAMELLAR.

5. *Antigorite.* Thin lamellar in structure, easily separating into translucent or subtransparent folia; H. = 2·5; G. = 2·622; color brownish green by reflected light, and leek-green by transmitted; feel smooth, but not greasy. Optical characters more distinct than with most other varieties (see above). Named from the locality, Antigorio valley, Piedmont.

6. *Williamsite* Shepard. A lamellar impure serpentine, of apple-green color, with H. = 4·5 and G. = 2·59–2·64, from Texas, Pa. Graduates into a massive granular variety.

C. THIN FOLIATED.

7. *Marmolite.* Thin foliated: the laminæ brittle but easily separable, yet graduating into a variety in which they are not separable. G. = 2·41; luster pearly; colors greenish white, bluish white to pale asparagus-green. From Hoboken, N. J.

8. *Thermophyllite* occurs in small scaly crystals aggregated into masses, with an amorphous steatite-like base. B.B. crystals exfoliate like vermiculite or pyrophyllite. H. = 2·5; G. = 2·61. Luster of cleavage surface pearly; color light brown to silver-white and yellowish brown. From Hopansuo, Finland.

D. FIBROUS.

9. *Chrysotile.* Delicately fibrous, the fibers usually flexible and easily separating; luster silky, or silky metallic; color greenish white, green, olive-green, yellow, and brownish;

G. = 2·219. Often constitutes seams in serpentine. It includes most of the silky *amianthus* of serpentine rocks and much of what is popularly called *asbestus* (asbestos). The Canadian chrysotile is often called in the trade *Bostonite*. The original chrysotile was from Reichenstein.

10. *Picrolite*. Columnar, but fibers or columns not easily flexible, and often not easily separable, or affording only a long splintery fracture; color dark green to mountain-green, greenish, gray, and brown. The original was from Taberg, Sweden. *Metaxite*, picrolite, consisting of separable but brittle columns, of a greenish white color, and weak pearly luster; H. = 2–2·5; G. = 2·52. From Schwarzenberg. Passes into a laminated variety. *Baltimorite* is picrolite from Bare Hills, Md., of a grayish green color; silky luster, opaque, or subtranslucent, with H. = 2·5–3.

F. SERPENTINE ROCKS. Serpentine often constitutes rock-masses. It frequently occurs mixed with more or less of dolomite, magnesite, or calcite, making a rock of clouded green, sometimes veined with white or pale green, called *verd-antique*, *ophiolite*, or *ophicalcite*. Serpentine rock is sometimes mottled with red, or has something of the aspect of a red porphyry; the reddish portions containing an unusual amount of oxide of iron. Any serpentine rock cut into slabs and polished is called *serpentine marble*. Verde di Prato is a variety from near Florence.

Microscopic examination has established the fact that serpentine in rock-masses has been largely produced by the alteration of chrysolite, and many apparently homogeneous serpentines show more or less of this original mineral. In other cases it has resulted from the alteration of pyroxene or amphibole. Sections of the serpentine derived from chrysolite often show a peculiar structure, like the meshes of a net; the lines marked by grains of magnetite, following the original cracks and cleavage-directions of the chrysolite. The serpentine from pyroxene and amphibole commonly shows a characteristic grating structure.

**Comp.**—A magnesium silicate, $H_4Mg_3Si_2O_9$ or $3MgO.2SiO_2.2H_2O$ = Silica 44·1, magnesia 43·0, water 12·9 = 100. Iron protoxide often replaces a small part of the magnesium; nickel in small amount is sometimes present. The water is chiefly expelled at a red heat and hence must be all chemically combined, see below. The formula has also been written $H_2Mg_3Si_2O_8 + H_2O$, or as a hydrous orthosilicate.

Clarke and Schneider obtained on the serpentine of analyses quoted below, for the loss of water·

| | 105° | 250° | 383°–412° | 498°–527° | red ht. | white ht. |
|---|---|---|---|---|---|---|
| Anal. 16*a* | 0·96 | 0·55 | 0·27 | 0·23 | 12·37 | 0·28 |
| " 2 | 1·20 | 0·55 | | 13·01 | | |
| " 43 | 2·04 | 0·71 | 0·27 | 0·56 | 11·81 | 0·25 |
| " 38 | 1·53 | 0·44 | 0·62 | — | 10·58 | 0·04 |
| " 18 | 2·26 | 1·01 | 0·98 | 0·42 | 11·32 | 0·17 |

Further the same authors have determined the amount of bases, MgO and $R_2O_3$, removed as chlorides after heating from 41 to 78 hours at 383° to 412°, in dry hydrochloric acid gas, thus:

MgO 10·14 16·73 9·98 11·38 15·25. Also of $R_2O_3$ 0·43 0·66 0·51

It is inferred that the magnesium thus removed is present in the mineral as the group MgOH, and hence the formula is written $H_3(MgOH)Mg_2(SiO_4)_2$. Am. J. Sc., **40**, 308, 1890.

Tschermak, however, argues for the presence of two magnesium hydroxyl groups, giving the formula $H_2(MgOH)_2MgSi_2O_7$.

Serpentine is closely related to the chlorites, both optically (as noted above) and chemically as urged by Wartha, Földt. Közl., **16**, 79, 1886, Clarke and Schneider, l. c., and more particularly by Tschermak, Ber. Ak. Wien, **99** (1), 80, 1890, **100** (1), 32, 1891. Cf. also p. 643 *et seq.*

The following are typical analyses commencing with the massive varieties; many others are given in 5th Ed., pp. 466, 467; see also references below, p. 673.

In general the analyses agree remarkably well with the theoretical values considering the pseudomorphous character of the material. Alumina is often present, especially when the original mineral was aluminous; it is possible, as urged by Tschermak in the case of the Sprechenstein mineral, that the aluminous kinds are sometimes intermediate forms between serpentine and penninite, but this is not as yet sufficiently proved.

Paijkull mentions a serpentine from Långban containing 7 8 p. c. MnO, G. För. Förh., **3**, 351, 1877; Koenig has described a serpentine-like mineral from Franklin Furnace, N. J., with 7·4 MnO, 3·9 ZnO, Proc. Acad. Philad., 350, 1886.

A chrysotile embedded in the blocks of a lime-breccia from Médoux near Bagnerres-de-Bigorre gave Goguel 12·3 p. c. CaO and 5 p. c. $Al_2O_3$, but perhaps from impurity. Bull. Soc. Min., **11**, 155, 1888.

**Pyr., etc.**—In the closed tube yields water. B.B. fuses on the edges with difficulty. F. = 6. Gives usually an iron reaction. Decomposed by hydrochloric and sulphuric acids. From chrysotile the silica is left in fine fibers.

**Obs.**—Serpentine, more or less pure, often constitutes mountain masses and in this form is widely distributed. It is a metamorphic rock, resulting from the alteration of other rocks, particularly of peridotyte. Crystals of serpentine, pseudomorphous after monticellite, occur in the Fassathal, Tyrol; near Miask at Lake Aushkul, Barsovka. Ekaterinburg, and elsewhere; in Norway, at Snarum; etc. Fine precious serpentines come from Falun and Gulsjö in Sweden, the Isle of Man, the neighborhood of Portsoy in Banffshire, the Lizard, Cornwall (anals. 4–8), Corsica, Siberia, Saxony, etc. At Zermatt (*schweizerite*). The names of many other localities are given above.

In N. America, in *Maine* at Deer Isle, precious serpentine of a light green color. In *Vermont,* at New Fane, Cavendish, Jay, Roxbury, Troy, Westfield. In *Mass.,* fine at Newburyport; Blandford with schiller spar, and the marmolite variety; also at Westfield, Middlefield, Lynnfield, Newburyport, and elsewhere. In *R. Island,* at Newport; the bowenite at Smithfield. In *Conn.,* near New Haven and Milford, at the verd-antique quarries. In *N. York,* at Phillipstown in the Highlands; at Port Henry, Essex Co.; at Antwerp, Jefferson Co., in crystals; at Syracuse, east of Major Burnet's, interesting varieties; in Gouverneur, St. Lawrence Co., in crystals, and also in Rossie, two miles north of Somerville; at Johnsburg in Warren Co.; Davenport's Neck, Westchester Co., affording fine cabinet specimens; in Cornwall, Monroe, and Warwick, Orange Co., sometimes in large crystals at Warwick; and from Richmond to New Brighton, Richmond Co. In *N. Jersey,* at Hoboken, with brucite, magnesite, etc., and the marmolite variety; also at Frankfort and Bryan; at Montville, Morris Co., silky fibrous (chrysotile) and retinalite, with common serpentine, produced by the alteration of pyroxene, Merrill, l. c. In *Penn.,* massive, fibrous, and foliated, of various colors, purple, brown, green, and gray, at Texas, Lancaster Co.; also at Nottingham and West Goshen, Chester Co.; at West Chester, Chester Co., the *williamsite;* at Mineral Hill, Newtown, Marple, and Middletown, Delaware Co.; a variety looking like meerschaum or lithomarge at Middletown; at Easton, pseudomorphous after pyroxene and amphibole. In *Maryland,* at Bare Hills; at Cooptown, Harford Co., with diallage; also in the north part of Cecil Co. In *California,* at various points in the Coast Range (cf. Becker, l. c.).

In *Canada,* abundant among the metamorphic rocks of the Eastern Townships and Gaspé peninsula, Quebec; at Thetford, Coleraine, Broughton, Orford, S. Ham, Bolton, Shipton, Melbourne, etc. The fibrous variety chrysotile (asbestus, bostonite) often forms seams, several inches in thickness in the massive mineral, and is now extensively mined for technical purposes. Massive Laurentian serpentine also occurs in Grenville, Argenteuil Co., Quebec, and North Burgess, Lanark Co., Ontario. In *N. Brunswick,* at Crow's Nest in Portland.

The names *Serpentine, Ophite, Lapis colubrinus,* allude to the green serpent-like cloudings of the serpentine marble. *Retinalite* is from ῥετινή, *resin; Picrolite,* from πικρός, *bitter,* in allusion to the magnesia (or Bittererde) present; *Thermophyllite* from θέρμη, *heat,* and φύλλον, *leaf,* on account of the exfoliation when heated; *Chrysotile,* from χρυσος, *golden,* and τίλος, *fibrous; Metaxite,* from μέταξα, *silk; Marmolite,* from μαρμαίρω, *to shine,* "in allusion to its pearly and somewhat metallic luster" (Nuttall).

**Artif.**—Formed by A. Gages in transparent amorphous mass, by placing a solution of gelatinous silicate of magnesium in a dilute solution of potash. It is deposited after some months' standing. (Rep. Brit. Assoc., 203, 1863.)

On the origin and occurrence of serpentine, see the following:

Rose, Pogg., **82**, 511, 1851. Tschermak, Ber. Ak. Wien **56** (1), 261, 283, 1867. Roth, Abh., Ak. Berlin, p. 339, 1869. Drasche, Min. Mitth., 1, 1871. Lemberg, Zs. G. Ges., **27**, 531, 1875. Weigand, Min. Mitth., 183, 1875. Bonney, Lizard, Q. J. G. Soc., **33** 884, 1877. Heddle, Trans. R. Soc. Ed., 28, 45, 1878. Cossa, Mem. Acc. Linc., 2, 933, 1878. Hare, Inaug. Diss. Breslau, 1879. Hussak, Min. Mitth., 5, 61, 1882. T. Sterry Hunt, Geol. Hist. Serpentine, 1883, Origin of Cryst. Rocks, 1884; Williams, Am. J. Sc., 34, 137, 1887. Merrill, Proc. U. S. Nat. Mus., 105, 1888. Becke, U. S. G. Surv., Mon. 13, 108, 1888. For a popular account, see the recent work by R. H. Jones (London, 1890): "Asbestos, its properties, occurrences and uses."

On the crystalline structure of serpentine, see the following:

Websky, Zs. G. Ges., 10, 277, 1856. Dx., Min., 1, 106 *et seq.*, 1862. Reusch, Pogg., **127**, 166, 1866. Wiik, Öfv. Finks. Vet. Soc., 17, 8, 1874–75. Hussak, Min. Mitth., 5, 61, 1883. Rosenbusch, Mikr. Phys., 557, 1886. Brauns, Jb. Min., Beil., 5, 275, 1887. Patton, Min. Mitth., 9, 85, 1887. Lévy-Lcx., Min. Roches, 278, 1888. Tschermak, Ber. Ak. Wien, **99** (1), 253, 1890, **100** (1), 32, 1891.

On the various forms of serpentine (derived from chondrodite) at the Tilly Foster Iron mine, Brewster, N. Y., see J. D. Dana, Am. J. Sc., 8, 375, 1874.

On the alteration-products derived directly or indirectly from the chrysolite rocks of Krems (Křemze), Bohemia, especially with reference to the origin and subsequent changes in the serpentine, see Schrauf, Zs. Kr., 6, 321, 1882 (see p. 666, also *Kelyphite*, p. 447). He shows that much serpentine is impregnated with opal-silica, and includes such occurrences under the general term *siliciophite*. This may be true of aphrodite, p. 675. *Enophite* is a chloritic serpentine-like alteration product; analysis:

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| G. = 2·64 | 38·40 | 3·71 | 3·11 | 4·51 | 30·46 | 3·21 | 17·06 = 100·46 |

On the alterations connected with the paleopikryte of Amelose near Biedekopf, cf. R. Brauns, Jb. Min., Beil.-Bd., 5, 275, 1887. *Webskyite* is an alteration-product of the serpentine. Amorphous. H. = 3. G. = 1·771. Color pitch-black with brownish green streak. Analysis.

⅔ $SiO_2$ 34·92 $Fe_2O_3$ $Al_2O_3$ 9·60 FeO 3·13 MgO 21·62 $H_2O$ 31·04 (below 110° 21 p. c.) = 100·31

Named after Prof. Martin Websky (1824–1886).

---

The following are magnesian silicates allied to serpentine but of somewhat doubtful character:

TOTAIGITE *Heddle*, Trans. R. Soc. Ed., 28, 455, 497, 1878. A serpentinous mineral appearing as a pseudomorphous substance surrounding malacolite and itself often enveloped in serpentine. Color pale fawn, sometimes blue-black. Soft. Analysis of a fawn-colored variety:

$SiO_2$ 37·22 $Al_2O_3$ 0·76 FeO 1·05 MnO 0·23 MgO 44·97 CaO 5·24 $H_2O$ 10·64 = 100·11

Occurs in a granular limestone at Totaig, Ross-shire, Scotland.

ZÖBLITZITE *Frenzel*, Min. Lex. Sachsen, 351, 1874, Jb. Min., 680, 1875.

Massive. Slightly brittle. Pale gray or yellowish white. H. = 3–4. Anal.—Melling, Rg., Min. Ch., 503, 1875. 2, 3, Frenzel, Jb. Min., 680, 1875.

| | | $SiO_2$ | $Al_2O_3$ | FeO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. Zöblitz | | 47·13 | 2·57 | 2·92 | 36·13 | 11·50 | = 100·25 |
| 2. Hrubschitz | | 42·57 | 9·12 | 1·82 | 32 90 | 13·19 | = 99·60 |
| 3. Kändler | G. = 2·49 | 42·44 | 4·67 | 0·91 | 38·49 | 13·48 | = 99·99 |

Occurs in serpentine at Zöblitz, similarly at Kändler near Limbach; also as an incrustation on chromite in serpentine at Hrubschitz, also at Lettowitz, both in Moravia. Frenzel finally calls zöblitzite a somewhat impure white serpentine.

METAXOITE *Arppe*, Finsk. Min., Act. Sc. Fenn., 6, 580, 1861, Holmberg, Vh. Min. Ges., 145, 1862.

Massive, compact; also radiated or granular crystalline. G. = 2·58–2·61. Color white to greenish blue. Anal.—1, 2, Asp, and 3, Hällsten, Arppe, Finsk. Min., l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. *Crystals* | 38·69 | 9·68 | 4·70 | *undet.* | 15·28 | *undet.* | 12·97 | |
| 2. " | 37·90 | 9·78 | 6·73 | 2·05 | 12·23 | 18·79 | 12·76 | = 100·24 |
| 2. *Amorphous* | 40·63 | 10·17 | 6·78 | *undet.* | 11·24 | 16·03 | 12·88 | |

Found near Lupikko in Finland, some versts south of Pitkäranta, with serpentine. Named from its nearness to *metaxite.*

HYDROPHITE. Hydrofit *Svanberg*, Ak. H. Stockh., 186, 1839. Jenkinsite *Shepard*, Am. J. Sc., 13, 392, 1852. Eisengymnit.

Massive; sometimes in fibrous crusts.

H. = 2·5–3·5. G. = 2·65, hydrophite; 2·4–2·6, jenkinsite. Luster feeble, subvitreous. Color mountain-green to blackish green. Streak paler. Translucent to opaque.

*Jenkinsite* is apparently an iron serpentine; hydrophite the same with one more molecule of water. Websky regards hydrophite as impure *metaxite*, Zs. G. Ges., **10**, 284, 1858.

Anal.—1, Svanberg, l. c. 2, 3, Smith & Brush, Am. J. Sc., **16**, 369, 1853.

| | $SiO_2$ | $Al_2O_3$ | FeO | MnO | MgO | $H_2O$ |
|---|---|---|---|---|---|---|
| 1. Hydrophite | 36·19 | 2·90 | 22·73 | 1·17 | 21·08 | 16·08 $V_2O_5$ 0·11 = 100·26 |
| 2. Jenkinsite | 38·97 | 0·53 | 19·30 | 4·36 | 22·87 | 13·36 = 99·39 |
| 3. " | 37·42 | 0·98 | 20·60 | 4·05 | 22·75 | 13·48 = 99·28 |

In the closed tube gives off water. B.B. blackens and fuses at about 3 to a black magnetic globule. With the fluxes gives reactions for iron and manganese. Decomposed by hydrochloric acid.

*Hydrophite* occurs at Taberg in Småland, Sweden; *jenkinsite* at O'Neil's mine in Orange Co., N. Y., as a fibrous incrustation on magnetite. Named *Hydrophite* in allusion to the water present; and *Jenkinsite* after J. Jenkins of Monroe.

APHRODITE. Afrodit *Berlin*, Ak. H. Stockh., 167, 172, 1840.

A soft earthy mineral near sepiolite. G. = 2·21. Color milk-white. Opaque. Perhaps $H_6Mg_4Si_4O_{15}$ but of doubtful homogeneity, cf. Fischer, Zs. Kr., **4**, 368, 1880; Schrauf, ib., **6**, 353, 1882. Anal.—Berlin, l. c.:

| $SiO_2$ | MgO | MnO | FeO | $Al_2O_3$ | $H_2O$ |
|---|---|---|---|---|---|
| 51·55 | 33·72 | 1·62 | 0·59 | 0·20 | 12·32 = 100 |

From Långban, Sweden. Named from ἀφρός, *foam*.

Another magnesium silicate analyzed by Delesse gave: $SiO_2$ 53·5, MgO 28·6, $Al_2O_3$ 0·9 ($Fe_2O_3$ *tr.*), $H_2O$ 16·4 = 99·4, corresponding to $MgO.SiO_2.H_2O$.

Occurs in serpentine, of a white or yellowish color, with a waxy luster, and somewhat translucent. G. = 2·335.

*Hampshirite* is a name applied by Hermann to the steatite of certain steatitic pseudomorphs having mostly the form of quartz described and analyzed by Dewey (Am. J. Sc., **4**, 274, **5**, 249, **6**, 334, 1822, 1823), who obtained: $SiO_2$ 50·60, MgO 28·83, $Al_2O_3$ 0·15, FeO 2·59, MnO 1·10, $H_2O$ 15·00 = 98·27. Probably not homogeneous.

CEROLITE. Kerolith *Breithaupt*, Char., 145, 254, 1823. Cerolith *Glock.*, 1831. Kerolite.

Massive, reniform, compact or lamellar.

Fracture conchoidal. Feel greasy. H. = 2–2·5. G. = 2·3–2·4. Luster vitreous or resinous. Color greenish or yellowish white, yellow, reddish. Streak uncolored. Transparent to translucent.

Anal.—1, Kühn's scholars, Lieb. Ann., **59**, 368, 1846. 2, Kühn, l. c. 3, Hermann, J. pr. Ch., **95**, 134, 1865 4, Genth, Am. J. Sc., **33**, 203, 1862.

|---|---|---|---|---|
| 1. Frankenstein | 47·34 | — | 29·84 | 21·04 = 98·22 |
| 2. " | 46·96 | — | 31·26 | 21·22 = 99·44 |
| 3. L. Itkul, *green* G. = 2·27 | 47·06 | NiO 2·80 | 31·81 | 18·33 = 100 |
| 4. Harford Co., Md., *bl. wh.* | 51·09 | 0·23 | 28·28 | 20·91 = 100·51 |

B.B. blackens, but does not fuse. From Frankenstein in Silesia, associated with serpentine, and also, according to Kühn, brucite. Similar minerals occur at L. Itkul and with the serpentine of Harford Co., Maryland.

Named from κηρός, *wax*, and λίθος.

LIMBACHITE *Frenzel*, Jb. Min., 789, 1873; Min. Lex. Sachsen, 184, 1874. A mineral resembling cerolite occurring in the serpentine of Limbach, Saxony. Massive. G. = 2·395. Luster greasy. Color grayish to greenish white. Not hard nor brittle. Does not adhere to the tongue. Analyses, Frenzel:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | $H_2O$ |
|---|---|---|---|---|
| 41·42 | 22·09 | — | 23·67 | 12·47 = 99·65 |
| 42·03 | 19·56 | 1·46 | 25·61 | 12·34 = 101·00 |

A yellowish apple-green, massive, earthy mineral from Webster, Jackson Co., N. C., gave Dunnington, Ch. News, **25**, 270, 1872:

G. = 2·30 $SiO_2$ 43·87 $Al_2O_3$ 22·21 FeO 16·14 $Na_2O$ 1·05 $H_2O$ 16·37 = 99·64

The relations of the above are uncertain.

**482. DEWEYLITE.** *Emmons*, Man. Min. and Geol., 1826. Gymnite *Thomson*, Phil. Mag., **22**, 191, 1843. Eisengymnit *Hatle* and *Tauss*, Vh. G. Reichs., 226, 1887.

Amorphous, and having some resemblance to gum arabic, or a brownish or yellow resin. Brittle, and often much cracked.

H. = 2–3·5. G. = 2·0–2·2. Luster greasy. Color whitish, yellowish, wine-yellow, greenish, reddish. Translucent.

**Comp.**—A magnesian silicate near serpentine but with more water. Formula perhaps $4MgO.3SiO_2.6H_2O$ = Silica 40·2, magnesia 35·7, water 24·1 = 100.

**Anal.**—1, Brush, Dana Min., 286, 1854. 2, Thomson, l. c. 3, Œllacher, Zs. G. Ges., **3**, 222, 1851. 4, Hatle and Tauss, l. c. Also Haushofer, Widtermann, 5th Ed., p. 470.

| 1. Texas, Pa. | | 43·15 | 35·95 | — | 20·25 | — $Al_2O_3$ *tr.* = 99·35 |
| 2. Bare Hills, Md. | G. = 2·22 | 40·16 | 36·00 | — | 21·60 | 1·16 CaO 0·80, $Al_2O_3$ *tr.* = 99·72 |
| 3. Tyrol, Fleimsthal | G. = 2·05 | 40·40 | 35·85 | — | 22 60 | 0·38 apatite 0·78 = 100 |
| 4. Kraubath, *Eisengymnite* | | 42·32 | 30·81 | 4·89 | 20·47 | — = 98·49 |

Half the water in 4 is lost at 110°–120°, the remainder only at a red heat.

**Pyr., etc.**—In the closed tube gives off much water. B.B. becomes opaque, and fuses on the edges. Decomposed by hydrochloric acid.

**Obs.**—Occurs with serpentine in the Fleimsthal, Tyrol; at Passau in granular limestone; also at Texas, Penn., and the Bare Hills, Md.; at Middlefield, Mass. Named after Prof. Chester Dewey (1784–1867). The gymnite of Thomson, named from γυμνός, *naked*, in allusion to the locality at Bare Hills, Md., is the same species.

*Eisengymnite* occurs intermixed with serpentine and gymnite at Kraubath, Styria, of a bright red color. H. = 3. G. = 1·986 of material not entirely pure.

**483. GENTHITE.** Nickel-Gymnite *Genth*, Kell. & Tiedm. Monatsb., **3**, 487, 1851. Genthite *Dana*, Am. J. Sc., **44**, 256, 1867.

Amorphous, with a delicately hemispherical or stalactitic surface, incrusting.

H. = 3–4; sometimes (as at Michipicoten) so soft as to be polished under the nail, and fall to pieces in water. G. = 2·409. Luster resinous. Color pale apple-green, or yellowish. Streak greenish white. Opaque to translucent.

**Comp.**—A gymnite with part of the magnesium replaced by nickel $2NiO.2MgO.3SiO_2.6H_2O$ = Silica 34·8, nickel protoxide 28·8, magnesia 15·5, water 20·9 = 100.

**Anal.**—1, Genth, l. c. 2, Hunt, Rep. G. Canada, 507, 1863.

| | $SiO_2$ | NiO | FeO | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|
| 1. Texas, Pa. | 35·36 | 30·64 | 0·24 | 14·60 | 0·26 | 19·09 = 100·19 |
| 2. Michipicoten Id. | 33·60 | 30·40 | 2·25 | 3·55 | 4·09 | 17·10 $Al_2O_3$ 8·40 = 99·39 |

The so-called genthite from Webster, Jackson Co., N. C., gave Dunnington (Ch. News, **25**, 270, 1872): $SiO_2$ 49·89, MgO 22·35, NiO 16·60, FeO 0·06, $H_2O$ 12·36 = 101·26. Occurs as an apple-green incrustation. G. = 2·48. The same mineral has given Walker results leading to a sepiolite formula (see p. 681).

After drying at a temperature above 100° C., Hunt obtained: $SiO_2$ 35·80, NiO 32·20, $H_2O$ 12·20.

**Pyr., etc.**—In the closed tube blackens and gives off water. B.B. infusible. With borax in O.F. gives a violet bead, becoming gray in R.F. (nickel). Decomposed by hydrochloric acid without gelatinizing.

**Obs.**—From Texas, Lancaster Co., Pa., in thin crusts on chromite; on Michipicoten Id., Lake Superior, of a greenish yellow to apple-green color. Also reported from near Malaga, Spain, with chromite and talcose schist; and by Wiser, from the Saasthal in the Upper Valais.

*Röttisite* Breith., B. H. Ztg., **18**, 1, 1859, may be essentially the above. It occurs with phosphate of nickel at Röttis in Voigtland, in amorphous masses and reniform incrustations, apple-green or emerald-green, of little luster, translucent to subtranslucent, but opaque when earthy, with H. = 2–2·25, and G. = 2·358–2·370.

483A. GARNIERITE *W. B. Clarke*, 1874. *Garnier*, Bull. Soc. G., **24**, 438, 1867. A new mineral from Noumea, New Caledonia, *A. Liversidge*, J. Ch. Soc., **12**, 613, July, 1874; Noumeite, Noumeaite, *Id.*, Proc. Roy. Soc., N. S. W., Dec. 9, 1874; Sept. 1, 1880; Min. N. S. W., 275, 1888. Numeite.

Amorphous. Soft and friable. G. = 2·3–2·8. Luster dull. Color bright apple-green, pale green to nearly white. In part unctuous; sometimes adheres to the tongue.

An important ore of nickel, consisting essentially of a hydrated silicate of magnesium and nickel, perhaps $H_2(Ni,Mg)SiO_4$ + aq, but very variable in composition, particularly as regards the mutual replacement of nickel and magnesium, and not always a homogeneous mineral. Liversidge has attempted to distinguish two varieties, one of which is dark green and unctuous, *noumeite;* the other rarer, pale green and adhesive to the tongue, *garnierite* (anal. 7).

**Anal.**—1 Dann (?), Ber. nied. Ges., Jan. 7, 1878. 2, Garnier, C. R., **86**, 684, 1878. 3, Kiepenheuer, Ber. nied. [a] At 100° in (1) 4·05; in (4) 6·44; in (5) 8·65; (9) 10·95 (105°); in (10) 11·28; in (11) 14·30.

[b] Soluble $SiO_2$ 0·70. [c] Do., in (11) 0·13. [d] First dried at 100°. [e] At 110°, 8·87.

Occurs in veins traversing a serpentine rock near Noumea, capital of New Caledonia; associated with chromic iron and steatite; also at numerous other points on the island. The three chief districts are the Kanala-Méré-Kuana, Thio-Port Bouquet, and Bourindi (cf. Min Res. U. S., 300, 1885)

The supply is very large, and the amount that can be mined in general greater than the market calls for; it is stated that for several years 1000 tons of the ore per annum have been marketed. Meissonier has reported the existence of similar deposits in the province of Malaga, Spain, C. R., 83, 229, 1876.

Deposits of a similar ore, perhaps of large extent, occur at Riddle in Douglas County, southern Oregon. Also at Webster, Jackson Co., N. C.; in both cases in connection with a peridotyte. Clarke (l. c.) shows that the former may owe their origin to a nickel-bearing chrysolite, and the North Carolina mineral probably had the same origin (Biddle, Min. Res., 170, 1886).

DE SAULESITE *Koenig*, Proc. Ac. Philad., 185, 1889

A hydrous silicate of nickel and zinc, associated with chloanthite and a nickel arsenate. It is amorphous, of a yellowish green, apple- or emerald-green color, and occurs as an incrustation or filling cavities in purple fluorite. Analysis gave.

| $SiO_2$ | NiO | ZnO | FeO | CaO | MgO | $H_2O$ | $As_2O_5$ |
|---|---|---|---|---|---|---|---|
| 31·62 | 38·22 | 4·00 | 2·03 | 0·70 | 0·42 | 16·58[a] | 4·77 = 98·34 |

[a] At 100° 9·44 p. c.; at 600° 7·14.

From the Trotter mine at Franklin Furnace, N. J.; named after the manager, Major A. B. de Saules.

The following are other nickel silicates, of doubtful character:

PIMELITE. Grüner Chrysopraserde (fr. Kosemütz) *Klapr.*, Schrift., Ges. N. Berlin, 8, 17, 1788, Beitr., 2, 134, 1797. Pimelit *Karst.*, Tab., 28, 72, 1800.

Massive or earthy. H. = 2·5. G. = 2·23–2·3; 2·71–2·76, Baer. Luster weak, greasy. Color apple-green. Streak greenish white. Translucent to sub-translucent. Feel greasy. Does not adhere to the tongue. Anal.—1, Klaproth, l.c., and Rg., Min. Ch., 871, 1860. 2, W. Baer, J. pr. Ch., **55**, 49, 1852.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | NiO | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. *Chrysoprase earth* | 35·00 | 5·00 | 4·58 | 15·63 | 1·25 | 0·42 | 38·12 = 100 |
| 2. *Hard Pimelite* | 35·80 | 23·04 | 2·69 | 2·78 | 14·66 | — | 21·03 = 100 |

Pimelite gives water in the closed tube, is infusible B.B., and with the fluxes reacts for nickel. Decomposed by acids. From Silesia and elsewhere. Named from *πιμελή, fatness.*

ALIPITE. Pimelit *Schmidt*, Pogg., **61**, 388, 1844. Alipit *Glock.*, 1845. Massive; earthy. H. = 2·5. G. = 1·44–1·46, Schmidt. Color apple-green. Not unctuous. Adheres to the tongue. Analysis.—Schmidt.

$SiO_2$ 54·63 $Al_2O_3$ 0·30 NiO 32·66 FeO 1·13 MgO 5·89 CaO 0·16 $H_2O$ 5·23 = 100

From Silesia. Named from the Greek *ἀλιπής, not greasy.*

REFDANSKITE *Hermann*, J. pr. Ch., **102**, 405, 1867. An earthy mineral occurring in masses which fall to powder under slight pressure. Adheres to the tongue. Color dirty grayish green. G. = 2·77. From Revdinsk, Urals. Analysis:

$SiO_2$ 32·10 $Al_2O_3$ 3·25 FeO 12·15 NiO 18·33 MgO 11·50 $H_2O$ 9·50 Sand 13·00 = 99·83

---

**484. TALC.** *Μαγνῆτις λίθος Theophr.* Magnetis *Germ.* Talck, Glimmer, *Agric.*, Foss., 254, Interpr., 466, 1546. Talk, Creta Brianzonia, C. Hispanica, C. Sartoria, Telgsten = Lapis Ollaris *Wall.*, Min, 133, 134, 1747. Talcum, Tälgsten, Speckstein, Steatites, *Cronst.*, Min., 89, 75, 1758. Talc, Soapstone, Steatite, Potstone. Craie de Briançon, etc., *Fr.* Pyrallolite pt. *Nordensk.*, Schw. J., **31**, 389, 1820. Rensselaerite *Emmons*, Rep. G. N. Y., 152, 1837. Agalite.

Orthorhombic or monoclinic. Rarely in tabular crystals, hexagonal or rhombic with prismatic angle of 60°. Usually foliated massive; sometimes in globular and stellated groups; also granular massive, coarse or fine; fibrous (pseudomorphous); also compact or cryptocrystalline.

Cleavage: basal perfect. Sectile. Flexible in thin laminæ, but not elastic. Percussion-figure a six-rayed star, orientated as with the micas. Feel greasy. H. = 1–1·5. G. = 2·7–2·8. Luster pearly on cleavage surface. Color apple-green to white, or silvery-white; also greenish gray and dark green; sometimes bright green perpendicular to cleavage surface, and brown and less translucent at right angles to this direction; brownish to blackish green and reddish when impure. Streak usually white; of dark green varieties lighter than the color. Subtransparent to translucent. Optically negative. Ax. pl. ∥ *a*. Bx ⊥ *c*. Axial angle:

| | | | |
|---|---|---|---|
| Rhode Island | $2E_r = 19° 1'$ | $2E_{bl} = 17° 56'$ | Dx.[1] |
| *Agalite* | $2E = 30°–40°$ | $\rho - v$, | Scheibe, Zs. G. Ges., **41**, 564, 1889. |

Steatite when rubbed with gun-cotton or Kienmayer's amalgam or fur becomes negatively electrified. Wied., Beibl., **22**, 707, 1889.

**Var.**—1. *Foliated. Talc.* Consists of folia, usually easily separated, having a greasy feel, and presenting ordinarily light green, greenish white, and white colors. G. = 2·55–2·78.

2. *Massive, Steatite* or *Soapstone* (Speckstein *Germ.*). *a.* Coarse granular, gray, grayish green, and brownish gray in colors; H. = 1–2·5. *Pot stone* or *Lapis ollaris* (Topfstein, Lavezstein, Giltstein *Germ.*) is ordinary soapstone, more or less impure. *b.* Fine granular or cryptocrystalline, and soft enough to be used as chalk; as the *French chalk* (*Craie de Briançon*), which is milk-white with a pearly luster. *c. Indurated talc.* An impure slaty talc, harder than ordinary talc. Talcose slate is a dark, slaty, argillaceous rock, having a somewhat greasy feel, which it owes to the presence of more or less talc.

Much of the steatite is pseudomorphous like the following.

3. *Pseudomorphous. a.* Fibrous, fine to coarse, altered from enstatite. *b. Rensselaerite,* cryptocrystalline, or wax-like in composition, but often having the form and cleavage of salite or pyroxene, and evidently pseudomorphous; colors whitish, yellowish, grayish, greenish white to very dark, and sometimes pearl-white; H. = 3–4; G. = 2·874 Beck; 2·757, fr. Grenville, 2·644, fr. Charleston Lake, in Canada, Hunt; usually translucent in pieces a fourth of an inch thick. Some agalmatolite is here included. Anal. 15 is of a variety of talc produced from chrysolite.

*Pyrallolite* is partly pseudomorphous steatite, after pyroxene, like rensselaerite. It varies exceedingly in composition, as shown by Arppe and others, and as recognized by A. E. Nordenskiöld in his Finland Mineralogy, the silica ranging from 49 to 76 p. c. It includes pyroxene, therefore, in various stages of steatitic alteration.

**Comp.**—An acid metasilicate of magnesium, $H_2Mg_3Si_4O_{12}$ or $H_2O.3MgO.4SiO_2$ = Silica 63·5, magnesia 31·7, water 4·8 = 100. The water goes off only at a red heat. Nickel is sometimes present in small amount.

Clarke and Schneider (Am. J. Sc., **40**, 306, 1890) have obtained the following water determinations (anal. 17):

| 105° | 250°–300° | red heat | white heat |
|---|---|---|---|
| 0·07 | 0·06 | 4·43 | 0·35 |

Also when treated with dry hydrochloric-acid gas for 15 hours at 383°–412° no appreciable change of weight resulted. Further, upon intense ignition over the blast-lamp and subsequent boiling with sodium carbonate solution 15·36 p. c. $SiO_2$ was given up according to the reaction:

$$H_4Mg_3Si_4O_{12} = 3MgSiO_3 + SiO_2 + H_2O.$$

The solution, however, had no effect upon the mineral before ignition. The stability with acids and liberation of silica as noted make it reasonably certain that the formula of an acid metasilicate, as written above, is correct.

[a] MnO. [b] Incl. $Fe_2O_3$.

Bachman has described (Am. Ch. J., **10**, 45, 1886) a mineral from Webster, Jackson Co., N. C., occurring in minute micaceous scales of a pale yellowish green color; readily crushed to an unctuous powder. Analysis gave:

| | $SiO_2$ | NiO | MgO | $H_2O$ | $Al_2O_3$ | FeO | |
|---|---|---|---|---|---|---|---|
| G. = 2·31 | 53·91 | 15·91 | 19·39 | 6·30[a] | 2·65 | 1·46 | = 99·62 |

[a] At 100° 0·80.

This corresponds to a highly nickeliferous hydrated talc.

The steatite from Göpfersgrün, in which Klaproth found but 59·5 per cent of silica, along with MgO 30·5, FeO 2·3, $H_2O$ 5·5 (Beitr., 2, 177, 1797), is what has been called *hydrosteatite.* The Fenestrelles (Piedmont) pseudomorph had the cleavage of amphibole; of those of Wunsiedel (from Göpfersgrün), 19 was a pseudomorph after dolomite.

**Pyr., etc.**—In the closed tube B.B., when intensely ignited, most varieties yield water. In the platinum forceps whitens, exfoliates, and fuses with difficulty on the thin edges to a white enamel. Moistened with cobalt solution, assumes on ignition a pale red color. Not decomposed by acids. Rensselaerite is decomposed by concentrated sulphuric acid.

**Obs.**—Talc or steatite is a very common mineral, and in the latter form constitutes extensive beds in some regions. It is often associated with serpentine, talcose or chloritic schist, and dolomite, and frequently contains crystals of dolomite, breunnerite, also asbestus, actinolite, tourmaline, magnetite.

Steatite is the material of many pseudomorphs, among which the most common are those after pyroxene, hornblende, mica, scapolite, and spinel. The magnesian minerals are those which commonly afford steatite by alteration; while those like scapolite and nephelite, which contain soda and no magnesia, most frequently yield pinite-like pseudomorphs. There are also steatitic pseudomorphs after quartz, dolomite, topaz, chiastolite, staurolite, cyanite, garnet, vesuvianite, chrysolite, gehlenite. Talc in the fibrous form is pseudomorph after enstatite. On pseudomorphs of talc after quartz, see Weinschenk, Zs. Kr., **14**, 305, 1888.

Apple-green talc occurs at Mt. Greiner in the Zillerthal, Tyrol; in the Valais and St. Gothard in Switzerland; also other places above mentioned; also in Cornwall, near Lizard Point, with serpentine; in Scotland, with serpentine, at Portsoy and elsewhere; on Unst, one of the Shetland islands; at Croky Head, Dunglow, Ireland, etc. A *fibrous* talc (pseudomorphous) with pearly luster, slightly greenish color, and greasy feel, has been described from Madagascar (anal. 25).

In N. America, foliated talc occurs in *Maine*, at Dexter. In *Vermont*, at Bridgewater, handsome green talc, with dolomite; at Athens or Grafton, Westfield, Marlboro, Newfane. In *New Hampshire*, at Francestown, Pelham, Orford, Keene, and Richmond. In *Mass.*, at Middlefield, Windsor, Blanford, Andover, and Chester. In *R. Island*, at Smithfield, delicate green and white in a crystalline limestone. In *N. York*, at Edwards, St. Lawrence Co., a fine fibrous talc (*agalite*) associated with pink tremolite; near Amity; on Staten Island, near the quarantine, common and indurated; four miles distant, in detached masses made up of folia, snow-white. In *N. Jersey*, at Lockwood, Newton, and Sparta. In *Penn.*, at Texas, Nottingham, Unionville; in South Mountain, ten miles south of Carlisle; at Chestnut Hill, on the Schuylkill, talc and also soapstone, the latter quarried extensively. In *Maryland*, at Cooptown, of green, blue, and rose colors. In *N. Car.*, at Webster, Jackson Co., a variety supposed by Genth to be altered chrysolite. In *Canada*, in the townships Bolton, Sutton, and Potton, Quebec, with steatite in beds of Cambrian age; in the township of Elzevir, Hastings Co., Ontario, an impure grayish var. in Archæan rocks.

The so-called *rensselaerite* occurs in northern New York, in the towns of Antwerp (with the form of pyroxene), Fowler, De Kalb, Edwards (at the iron mine, a white variety, from which ink-stands have been made), Russel, Gouverneur, Canton (in small crystals), Hermon (in large masses, crystalline massive); and in Canada, at Grenville, Charleston Lake, near Brockville, Rawdon, and Ramsay. It is often associated with crystalline limestone, and graduates at times imperceptibly into serpentine; its rock-masses are irregular, and are seldom continuous for more than three or four hundred yards.

A white steatite of a silvery-pearly luster was the *Magnetis* of Theophrastus—a stone, according to this author, of silvery luster, occurring in large masses, and easily cut or wrought. The word is the origin of the modern *magnesia*. Agricola, in his "Interpretatio Rerum Metallicarum" appended to his works (1546), gives as a German synonym of Magnetis, *Talck;* and he adds, as other synonyms, *Silberweiss* and *Katzensilber*, and also *Glimmer*, the German now for *mica*, evidently confounding the two minerals. He mentions its resistance to fire, and speaks of it as *lapis scissilis.*

Other later writers derive the word *talc* from the Arabic *talk;* and Aldrovandus (1648) states that it is of Moorish introduction, adding, "Hoc nomen apud Mauritanos *stellam* significare dicitur,"[1] *Stella Terræ*—Star of the Earth—being one old name of the mineral, given it because "like a star and with silvery luster it shines." Cæsius ("De Mineralibus," 1636) writes the word in Latin, *Talchus*, but most other writers of that century, *Talcum.*

The word *steatitis* occurs in Pliny as the name of a stone resembling fat; but no further description is given that can with certainty identify it.

Rensselaerite was named after Stephen Van Rensselaer, of Albany, N. Y.

**Ref.**—[1] Min., **1**, 97, 1862. N. R , 99 1867.

Talcoid *Naumann* is a snow-white, broadly-foliated talc of Pressnitz, described by Scheerer as *neutraler kieselsaurer Hydrotalc.* Analyses by Scheerer and Richter show 68 p. c. $SiO_2$. It may be only common talc with disseminated quartz.

**485. SEPIOLITE.** Meerschaum *Germ.*, Wern. Bergm., I., 377, 1788. L'Écume de mer *Fr.* Keffekill *Kirw.*, **1**, 144, 1794. Magnesite pt. *Brongn.*, Min., 1807, Magnesite *id.*, 1824. Sepiolith *Glock.*. Syn., 190, 1847.

Compact, with a smooth feel, and fine earthy texture, or clay-like; also rarely fibrous.

H. = 2–2·5. G. = 2. Impressible by the nail. In dry masses floats on water. Color grayish white, white, or with a faint yellowish or reddish tinge, bluish green. Opaque.

**Comp.**—$H_4Mg_2Si_3O_{10}$ or $2H_2O.2MgO.3SiO_2$ = Silica 60·8, magnesia 27·1, water 12·1 = 100. Some analyses show more water ($2H_2O$), which is probably to be regarded as hygroscopic. Copper and nickel may replace part of the magnesium.

**Anal.**—1–3, Scheerer, Pogg., **84**, 361, 362, 1851. 4, 5, Chester, Am. J. Sc., **13**, 296, 1877. 6, P. H. Walker, Am. Ch. J., **10**, 44, 1888. For other analyses, see 5th Ed , p. 456.

| | | | | NiO | | | | |
| 6. Webster, N. C. | G. = 2·53 | 55·38 | 15·62 | 17·84 | 10·77[d] | 0·56[e] | — | = 100·17 |

[a] Incl. 0·70 $Fe_2O_3$, 3·14 $Mn_2O_3$. [b] Incl. 1·02 $Fe_2O_3$, 2·09 $Mn_2O_3$. [c] Below 110°. [d] At 100°, 5·18 p. c. [e] $Fe_2O_3$.

19 to 20 per cent of water were found by Berthier in meerschaum from Madrid and Coulommiers, and 19·6 p. c. by Kobell in that of Greece, J. pr. Ch., **28**, 482, 1843. Döbereiner and Eisenach (J. pr. Ch., **17**, 157, 1839) also found two molecules of water (instead of 1) in the meerschaum of Asia Minor. Chester found that of 18 to 20 p. c. $H_2O$ about half went off below 110°, the remainder only from 200° to a red heat.

**Pyr., etc.**—In the closed tube yields first hygroscopic moisture, and at a higher temperature gives much water and a burnt smell. B.B. some varieties blacken, then burn white, and fuse with difficulty on the thin edges. With cobalt solution a pink color on ignition. Decomposed by hydrochloric acid with gelatinization.

**Obs.**—Occurs in Asia Minor, in masses in stratified earthy or alluvial deposits at the plains of Eskihi-sher, where, according to Dr. J. Lawrence Smith, it has proceeded from the decomposition of magnesium carbonate, which is embedded in serpentine in the surrounding mountains. He observes that more or less magnesium carbonate is often found in the meerschaum, Am. J. Sc., **7**, 268, 1849; also found in Greece; at Hrubschitz in Moravia; in Morocco; at Vallecas in Spain, in extensive beds, affording a light but valuable building stone. The mineral from Morocco, called in French *Pierre de savon de Maroc*, is used in place of soap at the Moorish baths in different places in Algeria.

A fibrous mineral, having the composition of sepiolite, occurs in a seam two inches wide in "a silver mine in Utah;" anals. 4, 5; one variety is colored green with copper which is regarded as replacing the magnesium. The mineral of anal. 6 occurs in thin (1–3 mm.) layers in serpentine at Webster, Jackson Co., N. C.

The word *meerschaum* is German for *sea-froth*, and alludes to its lightness and color. *Sepiolite* Glocker is from *σήπια, cuttle-fish*, the bone of which is light and porous; and being also a production of the sea, "deinde *spumam marinam* significabat," says Glocker.

Brongniart, in the first edition of his Mineralogy (1807), included under *Magnesite* (1) the carbonate, which he calls *Mitchell's magnesite* (see under MAGNESITE); (2) the hydrous silicate or meerschaum; and (3) the siliceous carbonate from Baudissero in Piedmont; he putting "Mitchell's magnesite," the carbonate, *first*. Karsten, in his "Tabellen," published the next year, separated from meerschaum the carbonate, and adopted for it the name *magnesite*, and in this he has been followed by all German and most other mineralogists. The application of the name *magnesite* to the hydrous silicate, done in the later writings of Brongniart and by subsequent French mineralogists, is hence in violation of the law of priority.

**486. CONNARITE.** Konarit *Breith.*, B. H. Ztg., **18**, 2, 1859. Conarite, Comarite *wrong orthog.*

Hexagonal? In small fragile grains and crystals, with perfect clinodiagonal cleavage, and supposed (Breith.) to be like vivianite in crystallization.

H. = 2·5–3. G. = 2·459–2·619. Color yellowish, pistachio- and siskin-green, olive-green. Streak siskin-green. In thin lamellæ translucent. Optically uniaxial, negative with strong double refraction[1].

**Comp.**—A hydrous nickel silicate, perhaps $H_4Ni_2Si_3O_{10} = 2H_2O.2NiO_2.3SiO_2$ = Silica 49·3, nickel protoxide 40·8, water 9·9 = 100.

**Anal.**—Winkler, B. H. Ztg., **24**, 335, 1865.

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | NiO | CoO | $H_2O$ | $P_2O_5$ | $As_2O_5$ | $SO_3$ | |
|---|---|---|---|---|---|---|---|---|---|
| 43·6 | 4·6 | 0·8 | 35·8 | 0·6 | 11·1 | 2·7 | 0·8 | *tr.* | = 100 |

**Obs.**—Occurs at the Hanns Georg mine, at Röttis, in Saxon Voigtland, with röttisite (p. 676) which, it is suggested, may be an amorphous form of connarite.

Named from *κόνναρος, an evergreen tree;* hence connarite is the proper form and not conarite, from *κοναρός, well fed*, nor comarite, from *κόμαρος, the strawberry-tree* (as suggested by Dx., Min., **2**, XLVI, 1874).

**Ref.**—[1] Btd., Bull. Soc. Min., **5**, 75, 1882.

**487. SPADAITE.** *Fr. v. Kobell*, Gel. Anz. München, **17**, 945, 1843, J. pr. Ch., **30**, 467, 1843.

Massive, amorphous.

Fracture imperfect conchoidal and splintery. H.=2·5. Luster a little pearly or greasy. Translucent. Color reddish, approaching flesh-red.

**Comp.**—Perhaps $5MgO.6SiO_2.4H_2O$ or $H_2Mg_5Si_6O_{18} + 3H_2O$ = Silica 57·0, magnesia 31·6, water 11·4 = 100 (Rg).

**Anal.**—Kobell:

$SiO_2$ 56·00 $Al_2O_3$ 0·66 FeO 0·66 MgO 30·67 $H_2O$ 11·34 = 99·33

**Pyr., etc.**—In the closed tube yields much water and becomes gray. B.B. melts to a glassy enamel. Dissolves in concentrated hydrochloric acid, the silica easily gelatinizing.

**Obs.**—From Capo di Bove, near Rome, filling the spaces among crystals of wollastonite, in leucitic lava. Named after Sign. Medici Spada.

---

**488. SAPONITE.** Terra porcellanea particulis impalpabilibus mollis, pt., Brianzoner Krita pt., Smectis, *Engelsk* Walklera. α hwit (Landsend i Cornwall), *Cronst.*, 75, 1758. Seifenstein (fr. Cornwall) *Klapr.*, Schrift nat. Ges. Berlin, **7**, 163, 1787. Beitr., **2**, 180, **5**, 22. Steatite of Cornwall *Kirw.*, Min., **1**, 152, 1794. Soapstone pt. Mountain Soap pt. Pierre à Savon *H.* Saponit *Svanberg*, Ak. H. Stockh., 153, 1840. Piotin *Svanberg*, Pogg., **54**, 267, 1841. Saponite, rosite, Pogg., **57**, 165, 1842. Thalite *Owen*, J. Ac. Massive. In nodules, or filling cavities.

Soft, like butter or cheese, but brittle on drying. G. = 2·24–2·30. Luster greasy. Color white, yellowish, grayish green, bluish, reddish. Does not adhere to the tongue.

**Comp.**—A hydrous silicate of magnesium and aluminium; but the material is amorphous and probably always impure, and hence analyses give no uniform results.

**Anal.**—1, Haughton, Phil. Mag., **10**, 253, 1855. 2, Svanberg, l. c. 3, 4, Smith & Brush, Am. J. Sc., **16**, 368, 1853. 5, Harrington, Can. Nat., **7**, 179, 1875. 6–17, Heddle, also Trans. R. **Pyr., etc.**—B.B. gives out water very readily and blackens; thin splinters fuse with difficulty on the edge. Decomposed by sulphuric acid.

**Obs.**—Occurs at Lizard Point, Cornwall, in veins in serpentine; at various localities in

Scotland, cf. Heddle, l. c., and anals. 6–17; at Svärdsjö in Dalarne (*piotine* and *saponite*); in the geodes of datolite at Roaring Brook, near New Haven, Ct.; in the trap of the north shore of Lake Superior, between Pigeon Point and Fond du Lac, in amygdaloid (*thalite* of Owen); George's Is., on north coast of Prince Edward Is.

*Bowlingite* is from Bowling near Dumbarton on the Clyde; it is shown to be saponite by Heddle; earlier analyses gave very discordant results, cf. App. III, p. 17, and Lcx., Bull. Soc. Min., 8, 97, 1885. *Cathkinite* is from the Cathkin Hills.

*Prasilite* of Thomson (p. 663) probably belongs here according to Heddle.

Saponite is from *sapo, soap;* and piotine from *πιότης, fat.*

**489. CELADONITE.** Terre verte de Verone *de Lisle*, Crist., 2, 502, 1783. Grünerde *Hoffm.*, Bergm. J., 519, 1788. Green Earth pt.; Green Earth of Verona. Seladonit *Glock.*, Syn., 193, 1847. Celadonite *Fr.*

Earthy or in minute scales. Very soft. Color deep olive-green, celandine-green, apple-green. Feel more or less greasy.

**Comp.**—A silicate of iron, magnesium, and potassium, formula doubtful.

**Anal.**—1–4, Heddle, Trans. R. Soc. Edinburgh, **29**, 102, 1879.

| | G. | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $K_2O$ | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. Scuir Mohr | 2·574 | 57·72 | 0·33 | 17·05 | 3·73 | 0·08 | 3·84 | 0·60 | 5·55 | 0·42 | 10·78 | =100·10 |
| 2. Tayport | 2·590 | 52·69 | 5·79 | 9·75 | 5·37 | 0·31 | 8·54 | 1·16 | 6·21 | 0·39 | 10·48 | =100·69 |

| 4. Giant's Causeway | 2·63 | 56·41 | 2·14 | 14·07 | 5·10 | 0·23 | 5·91 | 0·60 | 8·83 | — | 6·80 | =100·09 |

An early analysis by Klaproth (Beitr., **4**, 239, 1807) gave:

Mte. Baldo $SiO_2$ 53 $Fe_2O_3$ 28 MgO 2 $K_2O$ 10 $H_2O$ 6 = 99

According to Klaproth, and also later, von Kobell, *not* acted on by hydrochloric acid.

**Obs.**—From cavities in amygdaloid at Mte. Baldo near Verona. Also a similar mineral from Scotland (anal. 1–4).

Named in allusion to the ordinary color of the mineral, *celadon-green*, equivalent in French to sea-green (written *Seladon* in German), for which term the English substituted *celandine-green.** Celadon is the name of one of the characters in a French romance by d'Urfé, entitled Astrée, published in 1610. He was a weak verdant lover of insipid tenderness, and thence the application to the above variety of green. D'Urfé borrowed the name from Ovid; it comes originally from *κελάδων, burning.*

**490. GLAUCONITE.** Glaukonit *Keferstein*, Deutsch. geol. dargest., 5, 510, 1828, *Glocker*, Handb., 832, 1831. Grünerde pt. *Germ.* Green Earth pt. Terre verte pt. *Fr.* Chlorophänerit *Jenzsch*, Jahrb. Min., 798, 1855.

Amorphous, and resembling earthy chlorite. Either in cavities in rocks, or loosely granular massive.

H. = 2. G. = 2·2–2·4. Luster dull, or glistening. Color olive-green, blackish green, yellowish green, grayish green. Opaque.

**Comp., Var.**—Essentially a hydrous silicate of iron and potassium; but the material is mostly, if not always, a mixture, and consequently varies much in composition.

In most of the early analyses the state of oxidation of the iron was not determined, but according to Haushofer it is chiefly ferric iron.

The kinds of glauconite are:

1. Green earth of cavities in eruptive rocks; to which the *chlorophanerite* of G. Jenzsch may perhaps be added.

2. Green grains of sand beds or rocks, as of the green sand of the Chalk formation, rarely found in limestones; called *glauconite* (in allusion to the grayish green color). H. = 2; G. = 2·29–2·35; color olive-green to yellowish green.

**Anal.**—1–3, A. Kupffer, JB. Ch., 1307, 1870; also other anals. of Russian glauconites. 4, Haushofer, J. pr. Ch., **102**, 38, 1866, also ibid., **97**, 353, 1866; many other anals. (in 5th Ed., p. 463). 5, Dewalque, Ann. Soc. G. Belg., **2**, 3, 1877. 6, Bamberger, Min. Mitth., 271, 1877. 7, Heddle, Trans. R. Soc. Edinb., **29**, 79, 1879. 8, Gümbel, Ber. Ak. München, Dec. 4, 1886. 9, Knerr & Schoenfeld, Am. Ch. J., **6**, 412, 1884. 10, 11, T. S. Hunt, Rep. G. Canada, 486–488, 1863. Earlier analyses are given in 5th Ed., pp. 462, 463; also a summary by Gümbel, l. c.

---

* Jameson has *seladon-green* (from Werner) in his Treatise on the External Characters of Minerals, 1805; and *celandine-green* in his System of Mineralogy, **1**, 466. 1816.

[a] Carbonates.

**Pyr., etc.**—Yields water. Fuses easily to a dark magnetic glass. Some varieties are entirely decomposed by hydrochloric acid, while others are not appreciably attacked.

The glauconite grains are most abundant in the "green sand," of the Chalk formation, sometimes constituting 75 to 90 p. c. of the whole. They are often casts of the shells of Rhizopods. The material has also been found in Silurian rocks, and beds of other geological periods, and even in the shells of recent Rhizopods, and in fragments of coral obtained in deep-sea soundings (Am. J. Sc., **22**, 281, 1856). The glauconite of the Silurian, analyzed by Hunt, contains less iron and more alumina than that of the Chalk formation.

For a general discussion of the nature and method of formation of glauconite, see Gümbel, Ber. Ak. München, 417–449, Dec. 4, 1886.

A green calcite from Central India contains a skeleton of glauconite—separable by acids—constituting about 14 p. c. of the whole. Haughton names the rock, which is a mixture of calcite and glauconite, *Hislopite* (Phil. Mag., **17**, 16, 1859).

**491. PHOLIDOLITE.** Folidolit *G. Nordenskiöld*, G. För. Förh., **12**, 348. 1890.

In minute crystalline scales distinctly bounded on two sides inclined to each other 60°, parallel to which there are two systems of fine cracks each making 30° with the medial line, which is the trace of the twinning plane.

Cleavage: basal, perfect. G. = 2·408. Luster resinous to pearly. Color grayish yellow by reflected light; nearly colorless under the microscope. Optically biaxial, negative. Ax. pl. ∥ edges of scales. Ax. angle = 20° approx.

**Comp.**—Corresponds approximately to $5H_2O.K_2O.12(Fe,Mg)O.Al_2O_3.13SiO_2$

**Anal.**—

| $SiO_2$ | $Al_2O_3$ | FeO | MnO | MgO | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|
| 49·78 | 6·31 | 4·08 | 0·12 | 27·94 | 5·93 | 5·49 = 99·65. |

The material analyzed had been dried at 100° and the remaining water goes off only at a red heat; the air-dried mineral gives off 4·77 p. c. $H_2O$ over calcium chloride and 0·80 at 100°, or 5·57 in all, corresponding to another $5H_2O$.

Occurs at Taberg in Wermland, Sweden, with garnet, diopside, etc. Named φολίδος—φόλις, *scale*, εἶδος, *form*—in allusion to its micaceous structure.

---

Terra Samia, Collyrium, Aster, *Plin.*, **35**, 53. Marga porcellana, Leucargilla, pt., *Wall.*, 22, 1747. Terra Porcellanea *Cronst.*, 73, 1758. Porcelain Clay. Kaolin. Porzellanerde, Porzellanthon, *Germ.* Argiles à porcelaine *Fr.* Terre à foulon pt. Fr. = Fuller's Earth. Arcilla *Sp.*

Pholerite *Guillemin*, Ann. Mines, **11**, 489, 1825. Pholerite, Pelitische Felsittuffe von Chemnitz, *A. Knop*, Jb. Min., 540, 1859. Ancudit *O. Koch*, Inaug. Diss. Jena, 1884.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0{\cdot}5748 : 1 : 1{\cdot}5997$; $\beta = 83° 11'$ Miers[1].
$100 \wedge 110 = 29° 43'$, $001 \wedge \bar{1}01 = 76° 22\frac{1}{2}'$, $001 \wedge 011 = 57° 48\frac{1}{3}'$.

**Forms:** *b* (010, *i-ì*), *c* (001, *O*), *m* (110, *I*), *n* ($\bar{1}11$, 1).

Angles: *mm'''* = 59° 26', *bm* = *60° 17', *nn'* = 58° 23', *bn* = 60° 48½' (meas. 60° 44'), *cm* = *84° 5', *cn* = *78° 8'.

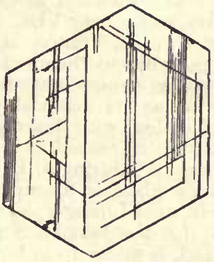
Also several doubtful pyramids.

If *m* be made 221 (= *M*, biotite) the forms noted for kaolinite approximate to those of biotite (p. 627); thus the measured angles for kaolinite as compared with the angles calculated for biotite are:

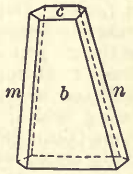
| | $001 \wedge 221$ | $001 \wedge \bar{1}11$ | $221 \wedge 2\bar{2}1$ | $\bar{1}11 \wedge \bar{1}\bar{1}1$ |
|---|---|---|---|---|
| Kaolinite | 84° 5' | 78° 8' | 59° 26' | 58° 23' |
| Biotite | 85° 38' | 81° 19' | 59° 48½' | 59° 14½' |

Usually in thin rhombic, rhomboidal, or hexagonal scales or plates with angles of 60° and 120° (f. 1), and sometimes twins, according to the mica law, made up of six sectors analogous to clinochlore. The scales rarely show distinct pyramidal planes and undetermined clinodomes; they are often grouped in fan-shaped forms. Also in crystals with pyramidal faces largely developed (f. 2), frequently twins (penninite law) with tw. plane and comp.-face *c* (001). Usually constituting a clay-like mass, either compact, friable, or mealy.

1.



2.



1, Johnson and Blake. 2, Anglesea, Dick.

Cleavage: basal, perfect. Flexible, inelastic. H. = 2–2·5. G. = 2·6–2·63. Luster of plates, pearly; of mass, pearly to dull earthy. Color white, grayish white, yellowish, sometimes brownish, bluish, or reddish. Scales transparent to translucent; usually unctuous and plastic.

Optically biaxial, negative. $Bx_o \perp b$. $Bx_a$ and ax. pl. inclined behind some 20° to normal to *c* (001) Dick. Axial angle large, approx. 90°. Dispersion weak.

**Var.**—1. *Kaolinite.* In crystalline scales, pure white and with a satin luster in the mass.

2. *Ordinary.* Common kaolin, in part in crystalline scales but more or less impure and either (*a*) *Argilliform*—soft, clay-like; (*b*) *Fariniform*—mealy, hardly coherent; or (*c*) *Indurated; Lithomarge* (*Steinmark* Germ.)—firm and compact; H. = 2–2·5. When pulverized, often shows a scaly texture. G. = 2·6, from Cainsdorf, solid var. *Tuesite* of Thomson is a lithomarge from Scotland, used sometimes for slate pencils; H. = 2·5; G. = 2·43–2·56; color milk-white.

3. *Ferruginous; Carnat* Breith. A firm lithomarge of a reddish white or flesh-red or brownish red color; the color owing to the presence of some iron oxide; H. = 2–3; G. = 2·543. Streak colorless; smooth to the touch

Myelin *Breith.*, Talksteinmark *Freiesleben* is simply kaolin according to Frenzel, J. pr. Ch., 5, 401, 1872. *Ancudite* (Koch) is an impure kaolin from Ancud (S. Carlos) on the island Chiloë, anal. 7.

Schlössing (l. c.) finds in certain French clays besides the crystallized kaolinite with the composition given below an *argile colloidale* which he makes lower in alumina and higher in silica, magnesia, and potash.

**Comp.**—$2H_2O.Al_2O_3.2SiO_2$ = Silica 46·5, alumina 39·5, water 14·0 = 100. The water goes off at a high temperature, above 330° Hillebrand (also, Dick).

Pholerite has been separated on the basis of Guillemin's analyses who gave 15 p. c. water, but there can be little doubt of its identity with kaolinite, cf. de Koninck, l. c.

**Anal.**—1, Tookey and Dick, Percy's Metallurgy, Fuel, 1875, and Min. Mag., **8**, 15, 1888. 2, Hillebrand, U. S. G. Surv., Bull. **20**, 97, 1885. 3, Hiortdahl, Jb. Min., **2**, 70, 1887. 4–6, L. L. de Koninck, Bull. Ac. Belg., **44**, 733, 1877.

For analyses of kaolins from France (Allier, Bretagne, Bayonne) and China, see Schlössing, C. R., **79**, 473, 1874. On the kaolins of the Bunt-Sandstein of Thuringia see Herold, Inaug. Diss. Jena, 1875 (E. E. Schmid, Zs G. Ges., **28**, 87, 1876).

For analyses of samples of "China clay" see Macadam, Min. Mag., **7**, 76, 1886; also Collins, ib., 205, who makes most of his purified clays agree with the formula $3H_2O.2Al_2O_3.4SiO_2$ = Silica 48·0, alumina 41·2, water 10·8 = 100. The correctness of the formula given above for pure kaolinite is sufficiently established by analyses 1–6.

**Pyr., etc.**—Yields water. B.B. infusible. Gives a blue color with cobalt solution. Insoluble in acids.

**Obs.**—Ordinary kaolin is a result of the decomposition of aluminous minerals, especially the feldspar of granitic and gneissoid rocks and porphyries. In some regions where these rocks have decomposed on a large scale, the resulting clay remains in vast beds of *kaolin*, usually more or less mixed with free quartz, and sometimes with oxide of iron from some of the other minerals present. Pure kaolinite in scales often occurs in connection with iron ores of the Coal formation. It sometimes forms extensive beds in the Tertiary formation, as near Richmond, Va. Also met with accompanying diaspore and emery or corundum.

Occurs in the coal formation at Cache-Aprés in Belgium; at St. Gilles and La Chartreuse near Lüttich and Bagatelle near Visé; Schlan in Bohemia, and at Röhe; in argillaceous schist at Lodève, Dept. of Hérault, France; at the Einigkeit mine at Brand, near Freiberg, and elsewhere in Saxony: as kaolin at Diendorf (Bodenmais) in Bavaria; at Zeisigwald near Chemnitz; as the gangue of topaz at Schneckenstein; with emery and margarite at Naxos; as the gangue of diaspore at Schemnitz; as the material of pseudomorphs after prosopite at Altenberg, showing well the hexagonal scales; with fluor at Zinnwald, a white powdery substance consisting of hexag. scales; at Rochlitz (*carnat*) in a porphyritic rock; as a cementing material in the sandstone (Bunt-Sandstein) of Thuringia; in seams in an argillaceous rock on the Tweed (*tuesite*), the Latin name of which place is *Tuesis*. In crystalline plates near Almwch on the island of Anglesey. At Yrieix, near Limoges, is the best locality of kaolin in Europe (a discovery of 1765); it affords material for the famous Sèvres porcelain manufactory. The dark colored clay of Stourbridge, England, is made up in large part of transparent laminæ. Large quantities of clay (kaolin) are found in Cornwall and West Devon, England, as described by Collins (l. c.) who gives the name carclazyte to a china-clay rock as at Carclaze, Cornwall, and petuntzyte to a less altered rock containing still fresh feldspar.

In the U. States, kaolin occurs at Newcastle and Wilmington, Del.; at various localities in the limonite region of Vermont (at Brandon, etc.), Massachusetts, Pennsylvania; Jacksonville, Ala.; Edgefield, S. C.; near Augusta, Ga.; and Johnson and Blake observed transparent hexagonal scales abundantly in a blue fire-clay from Mt. Savage, Md.; in the white clay of Brandon, Vt., Beekman, N. Y., Perth Amboy, N. J., Reading, and a locality in Chester Co., Pa., Long Island, and in white and colored clays of various other places. Near Richmond, Va., the mealy var. constitutes a bed of considerable extent in the Tertiary formation; at Tamaqua and Summit Hill in Carbon Co., Pa., it occurs in the Coal formation; in a sandstone of the L. Silurian, just below the Chaudière Falls, filling seams or fissures, often ½ in. thick, having an unctuous feel, and consisting of minute soft scales. At the National Bell mine, Red Mountain, Silverton, Colorado, in very pure form in cavities of a quartz vein material enclosed in a large eruptive mass; also at Bedwell Basin, Gunnison Co., Col. (anal. by Eakins, see U. S. G. Surv., Bull. **60**, 136, 1890).

The kaolin of the Thuringian Bunt-Sandstein is crystalline but contains various foreign substances as the *microschörlite* and *microvermiculite* of Schmid.

The name *Kaolin* is a corruption of the Chinese *Kauling*, meaning *high-ridge*, the name of a hill near Jauchau Fu, where the material is obtained; and the petuntze (peh-tun-tsz) of the Chinese, with which the kaolin is mixed in China for the manufacture of porcelain, is a quartzose feldspathic rock, consisting largely of quartz (S. W. Williams). The word *porcelain* was first given to the china-ware by the Portuguese, from its resemblance to the nacre of the sea-shells *Porcellana* (Cypræas), they supposing it to be made from egg-shells, fish-glue, and fish scales (S. W. Williams).

G. Vogt has investigated the yeou-ko of the Chinese and finds that it is made up of: Quartz 52·9 p. c., muscovite 31·3, sodium feldspar 13·4, calcium carbonate 2·0, hydrated silica 1·0 = 100·6. C. R, **110**, 43, 1890.

**Ref.**—[1] Min. Mag., **8**, 15, 1888, with corrected fundamental angles as later noted by the author, ibid., **9**, 4, 1890. Cf. also Johnson and Blake, Am. J. Sc., **43**, 35, 1867; R. C. Hills, Am. J. Sc., **27**, 472, 1884.

Reusch (Jb. Min., **2**, 70, 1887) makes the extinction in the scales oblique (12°) to an hexagonal edge, perhaps because the scales are often fan-shaped aggregates; the triclinic character does not seem to be confirmed by Dick and Miers.

MEERSCHALUMINITE *Ross.* Simlaite *Schrauf*, Vh. G. Reichs., 43, 1870. A kind of pholerite from near Simla, India. An analysis by Maskelyne and Flight (Ch. News, **22**, 260, 1870) gave:

$SiO_2$ 43·15 $Al_2O_3$ 41·07 $H_2O$ 15·78 = 100.

RECTORITE *R. N. Brackett* and *J. F. Williams*, Am. J. Sc., **42**, 16, 1891.

Monoclinic? In leaves or plates resembling mountain leather. Very soft, hardness less than that of talc. Feel soapy. Folia flexible, inelastic, and separating with easy cleavage.

Luster pearly. Color pure white, sometimes stained red with iron oxide. Optically biaxial, Bx ⊥ cleavage. 2E = 5° to 15° or 20°. Refractive index low.

Composition for the mineral dried at 110°, $HAlSiO_4$ or $Al_2O_3.2SiO_2.H_2O$ = Silica 50·0, alumina 42·5, water 7·5. Taking the water expelled at 110° as water of crystallization the formula is $2HAlSiO_4 + aq$, or empirically like kaolinite, from which it differs, however, since the latter mineral contains only water of constitution.

Analysis, on material dried at 110°:

| | $SiO_2$ | $Al_2O_3$ | $H_2O$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ |
|---|---|---|---|---|---|---|---|---|
| 1. | 52·72 | 36·60 | 7·76 | 0·25 | 0·45 | 0·51 | 2·83 | 0·26 = 101·38 |
| 2. | 52·88 | 35·51 | 7·72 | | | | | |

$H_2O$ at 110° in 1, 8·78 p. c.; in 2, 8·33.

B.B. infusible, but loses water and becomes brittle.

Found in seams in L. Silurian sandstone in the Blue Mountain mining district, Marble township, Garland Co., Arkansas, about 24 miles north of Hot Springs.

Named after Hon. E. W. Rector of Hot Springs.

LEVERRIERITE *P. Termier*, C. R., **108**, 1071, 1889; Ann. Mines, **17**, 372, 1890; Bull. Soc. Min., **13**, 325, 1890.

In vermiculate aggregates resembling helminth. Crystals hexagonal prisms, perhaps orthorhombic, with *c* (001), *b* (010), *m* (110), and $mm''' = 52°$ approx. Form and twinning like the micas.

Cleavage: basal, perfect. Soft. H. = 1·5. G. = 2·3–2·4. Luster vitreous to pearly. Colorless to brown. Optically −. Ax. pl. ∥ *b* (010). Bx ⊥ *c*. Ax. angle 45°–52°. $\beta = 1·6$. $\gamma - \alpha = 0·0075–0·0082$.

Comp.—A hydrated silicate of aluminium, but formula doubtful, as the material is more or less mixed with clay and analyses fail to agree. The author gives $2Al_2O_3.5SiO_2.5H_2O$ = Silica 50·5, alumina 34·3, water 15·2 = 100.

Anal.—1, A. Carnot, l. c.; C. R., **108**. 2, 3, quoted by Termier, l. c., Ann. Mines. 2, by Meunier.

Common in the black carbonaceous shales of the Departments de la Loire, France; thus at Beaubrun, Rive-de-Gier, Quartier-Gaillard near St. Etienne and other points; also in eruptive rocks (porphyry) of St. Etienne, at La Gagnérette, etc., Dept. du Gard.

Named after the mining engineer Le Verrier.

**493. HALLOYSITE.** Halloysite *Berthier*, Ann. Ch. Phys., **32**, 332, 1826. Galapektit, Gummit, *Breith.*, Char., 99, 1832. Glagerit *Breith.*, Handb., 357, 1841. Smectite *Salvetat*, Ann. Ch. Phys., **31**, 102, 1851. Steinmark or Lithomarge pt., Pseudo-Steatite pt., Glossecollite, *Shep.*, Min., 1857, App. to Suppl., p. iii.

? Lenzinit *John.*, Chem. Schrift., **5**, 193, 1816. ? Severite *Beud.*, Tr., 1824, in Index, and **2**, 36, 1832. ? Nertschinskite *Razumovski.* Bole pt. Milanit *Tietze*, Jb. G. Reichs., 588, 1870. Indianaite *Cox*, Rep. Geol. Indiana, 15, 1874, 154, 1878.

Massive. Clay-like or earthy.

Fracture conchoidal. Hardly plastic. H. = 1–2. G. = 2·0–2·20. Luster somewhat pearly, or waxy, to dull. Color white, grayish, greenish, yellowish, bluish, reddish. Translucent to opaque, sometimes becoming translucent or even transparent in water, with an increase of one-fifth in weight.

**Var.**—1. *Ordinary.* Earthy or waxy in luster, and opaque massive. *Galapectite* is halloysite of Anglar. *Pseudosteatite* of Thomson & Binney is an impure variety, dark green in color, with H. = 2·25, G. = 2·469. *Glagerite*, from Bergnersreuth in Bavaria, is proved to be halloysite by Fikenscher; it is white to yellowish white; G. = 2·35–2·38; H. = 2–2·5.

*Indianaite* is a white porcelain clay from Lawrence Co., Indiana, where it occurs with allophane in beds four to ten feet thick. H. = 2–2·5. G. = 2·31–2·53.

2. *Smectite* of Salvetat is greenish, and in certain states of humidity appears transparent and almost gelatinous; it is from Condé, near Houdan, France. Breithaupt's *Gummite* (Char., 99, 1832; is a "gum-like halloysite," not adhering to the tongue, from Anglar, though in his Handbuch, where the same locality is mentioned, he quotes Berthier's analysis of *collyrite* from the Pyrenees. *Glossecollite* is milk-white and earthy, but becomes translucent on the edges and a little opaline in water. It forms a seam 1 in. thick in a siliceous Silurian rock in Rising Fawn, Dade Co., Georgia. A yellow gum-like clay from near Budapest is referred to halloysite by Fr. Koch, Zs. Kr., **19**, 198, 1891.

3. *Lenzinite* is earthy, compact, white, translucent, and somewhat opaline, from Kall in the Eifel; and brownish, from rifts in pegmatyte, at La Vilate, near Chanteloube, in France. Leonhard considered it (Handb., 1826) a decomposed semiopal. It is described as not gelatinizing in acids. Named after the German mineralogist Lenz. *Nerchinskite* of Razumovski, a whitish or bluish earth from Nerchinsk, has been referred to lenzinite. *Severite*, or lenzinite of St. Sever, was first noticed in 1818, and analyzed in that year by Pelletier (J. Phys., **86**, 251, 1818). It has sometimes the semitransparency of opal, a soft feel, adheres strongly to the tongue, and makes no paste with water; it is from the upper arenaceous stratum in the gypsiferous Tertiary at St. Sever in France. It is not clear whether it belongs here or to kaolinite.

4. *Bole*, in part, may belong here; that is, those colored, unctuous clays containing more or less iron oxide, which also have about 24 p. c. of water; the iron gives it a brownish, yellowish, or reddish color; but more investigation is needed before it is known that they are not mere mixtures. *Oropion* of Glocker (Syn., 188, 1847) is a dark brown to black bole; it is the *Bergseife* (= mountain soap) of Werner (Ueb. Cronst., 189, 1780), having a greasy feel and streak, and H. = 1–2; the color is attributed to bituminous matters present. It is from Olkutsch in Poland. Where it belongs is doubtful. A similar kind from Thuringia has been analyzed by Bucholz (5th Ed., p. 477); but its identity with Werner's Polish *Bergseife* is not certain.

*Milanite* is from Maidanpek, Servia.

**Comp.**—A silicate of aluminium ($Al_2O_3.2SiO_2$) like kaolinite, but amorphous and containing more water; the amount is somewhat uncertain but, as shown by Le Chatelier, the formula is probably to be taken as $H_4Al_2Si_2O_9$ + aq, or $2H_2O.Al_2O_3.2SiO_2$ + aq = Silica 43·5, alumina 36·9, water 19·6 = 100.

Analyses by Le Chatelier on material heated to 250° gave the following results corresponding to the kaolinite formula $2H_2O.Al_2O_3.2SiO_2$; he finds further that the remaining water goes off only above 400°, the earlier amount at 150°. Bull. Soc. Min., **10**, 210, 1887.

| | $SiO_2$ | $Al_2O_3$ | $H_2O$ | | | $H_2O$ below 250° |
|---|---|---|---|---|---|---|
| Angleur | 46·3 | 39·5 | 14·3 | = | 100·1 | 8·5 |
| Huelgoat | 47·9 | 38·0 | 14·3 | = | 100·2 | 5·4 |

| Russia | 47·4 | 38·8 | 14·0 | = | 100·2 | 7·0 |

The following are analyses of *indianaite* by Pemberton on air-dried material:

| $SiO_2$ | $Al_2O_3$ | $H_2O$ | $H_2O$ at 100° C. | CaO,MgO | alkalies | | |
|---|---|---|---|---|---|---|---|
| 39·00 | 36·00 | 14·00 | 9·50 | 0·63 | 0·54 | = | 99·67 |
| 39·35 | 36·35 | 22·90 | | 0·40 | — | = | 99·00 |
| 38·90 | 37·40 | 23·60 | | *undet.* | — | = | 99·90 |

Helmhacker shows that some halloysites contain 4½ aq. and others 3 aq. when dried over sulphuric acid. He gives analyses 1–3. by Hofmann, Min. Mitth., **2**, 231, 1879. G. = 1·961–1·962, after exposure to dry air 1·985.

| | $SiO_2$ | $Al_2O_3$ | $H_2O$ above 100° | $H_2O$ at 100° | |
|---|---|---|---|---|---|
| 1. | 40·19 | 34·84[a] | 15·27 | 8·08 | CaO 2·55, MgO *tr.* = 100·93 |
| 2. | 36·34 | 32·34[b] | 18·29 | 10·59 | CaO 2·31 = 99·87 |
| 3. | 35·73 | 33·83[a] | 17·65 | 10·96 | CaO 2·58, CuO 0·10 = 100·85 |

[a] $Fe_2O_3,P_2O_5$ *tr.* [b] $Fe_2O_3$ 0·27 p. c.

Other analyses 5th Ed., pp. 476, 477.

Compact *glagerite* forming seams in clay at Gusevsk, Ural (Zs. Kr., **17**, 628, 1890), gave:

$SiO_2$ 45·85 $Al_2O_3$ 36·97 $Fe_2O_3$ *tr.* CaO 0·64 MgO 0·25 $H_2O$ 16·14 = 99·85

**Pyr., etc.**—Yields water. B.B. infusible. A fine blue with cobalt solution. Decomposed by acids.

**Obs.**—Occurs often in veins or beds of ore, as a secondary product; also in granite and other rocks, being derived from the decomposition of some aluminous minerals (localities mentioned above). The *Halloysite* of Housscha is derived from graphic granite.

The name *halloysite* is from Omalius d'Halloy (1707–1789), who first observed it.

**494. NEWTONITE.** *R. N. Brackett* and *J. F. Williams*, Am. J. Sc., **42**, 11, 1891.

Rhombohedral. In soft compact masses, resembling kaolin, the powder resolved under the microscope (× 400 to 500 diam.) into minute rhombs, nearly squares, but giving angles of 88° to 89°.

Soft. G. = 2·37. Color white. Extinction parallel to the diagonals of the rhombs.

**Comp.**—$H_8Al_2Si_2O_{11}$ + aq or $Al_2O_3.2SiO_2.5H_2O$ = Silica 38·5, alumina 32·7 water 28·8 = 100.

**Anal.**—1, 2, Brackett & Williams, l. c.

| | $SiO_2$ | $Al_2O_3$ | $H_2O$[a] | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 38·86 | 35·20 | 23·69 | 0·21 | 0·31 | *tr.* | [1·73] | | = 100 |
| 2. | 40·22 | 35·27 | 22·89 | 0·21 | 0·54 | *tr.* | 0·99 | 0·73 | = 100·85 |

[a] Ignition; at 110°–115°, 5·53 p. c. $H_2O$ in 1; 5·44 in 2.

**Pyr., etc.**—B.B. infusible; gives the alumina reaction with cobalt solution. Only slightly attacked by boiling hydrochloric acid, but almost completely decomposed by boiling concentrated sulphuric acid with separation of silica.

**Obs.**—Found on Sneed's Creek in the northern part of Newton Co., Arkansas. Occurs in lumps varying from a few ounces to forty pounds, embedded in a dark gray clay.

---

**495. CIMOLITE.** Κιμωλία *Theophr.* Cimolia *Plin.*, **35**, 57. Cimolit *Klapr.*, Beitr., **1**, 291, 1795. Pelikanit *Ouchakoff*, Bull. Ac. St. Pet., **16**, 129, J. pr. Ch., **74**, 254, 1858. Hunterite *Haughton*, Phil. Mag., **17**, 18, 1859, **23**, 50, 1862.

Terra Lemnia *Dioscor*, *Plin.*, etc. Sphragid *Karst.*, Tab., 28, 88, 1808. Ehrenbergit *Nöggerath*, Vh. Ver. Rheinl., **9**, 378, 1852. Anauxite *Breith.*, J. pr. Ch., **15**, 325, 1838.

Amorphous, clay-like, or chalky.

Very soft. G. = 2·18–2·30. Luster of streak greasy. Color white, grayish white, reddish. Opaque. Harsh. Adheres to the tongue.

**Comp.**—A hydrous silicate of aluminium, $2Al_2O_3.9SiO_2.6H_2O$ = Silica 63·4, alumina 23·9, water 12·7 = 100. Perhaps a basic salt.

**Anal.**—1, Klaproth, l. c. 2, Ilimov [Ann. J. M. Russ., 336, 1841] Rg., Min. Ch., 584, 1860. 3, v. Hauer, Jb. G. Reichs., **5**, 83, 1854. 4, Haughton, l. c. 5, Riggs, Am. J. Sc., **32**, 355, 1886. Also F. W. Clarke, Am. J. Sc., **28**, 23, 1884; Scharizer, Jb. G. Reichs., **32**, 488, 491, 1882.

[a] X = FeO,MnO,CaO,MgO.

The hunterite, according to the analysis, contains a little excess of silica, probably due to free quartz, as the material was gritty under the pestle.

**Pyr., etc.**—Yields water. B.B. becomes gray and finally burns white; infusible. With cobalt solution a blue color.

**Obs.**—From the island of Argentiera (Kimolos of the Greeks); Berg Hradischt, near Bilin, Bohemia (pseud. after augite, cf. Scharizer, l. c.); also from Ekaterinovska, district of Alexandrovsk, Russia; Government of Kiev, Russia; Nagpur, Central India, with orthoclase in granite. A related mineral (anal. 6) from Norway, Me., associated with tourmaline.

A light porous clay-like mineral of a dull white color, resembling meerschaum, has been investigated by Liversidge, Min N. S. W., 194, 1888. H. = 2–2·5. Specific gravity after immersion 1·168. Fracture conchoidal. Analysis:

$SiO_2$ 51·46[a] $Al_2O_3$ 37·72 $Fe_2O_3$ 0·46 CaO 0·34 MgO 1·25 $H_2O$ 7·62[b] $CO_2$ 1·54 = 100·39

[a] Soluble 0·11 p. c. [b] At 100°, 3·28 p. c.

From Richmond River, New South Wales.

**496. MONTMORILLONITE.** *Salvetat*, Ann. Ch. Phys., **21**, 376, 1847. Confolensite *Dufr.*, Min., 3. 583, 1856. Delanovit *Kenng.*, Jb. G. Reichs., **4**, 633, 1853. Delanouite *Dufr.*, Min., 3, 583, 1856. Stolpenit (= Bole of Stolpen) *Kenng.*, Min., 41, 1853. Saponite *Nicklès*, Ann. Ch. Phys., **56**, 46, 1859 = Pierre a savon (*Germ.* Bergseife) de Plombières. Steargillite *Meillet*, Dx., Min., **1**, 205, 1862. Erinite *Thomson*, Min., **1**, 341, 1836.

Massive, clay-like.

Very soft and tender. Luster feeble. Color white or grayish to rose-red, and bluish; also pistachio-green. Softens in water, and for the most part does not adhere to the tongue. Unctuous.

**Var.**—1. *Montmorillonite* is rose-red; from Montmorillon, France. *Confolensite* is paler rose-red; fr. Confolens, Dept. of Charente, at St. Jean-de-Côle, near Thiviers. *Delanouite* is similar in color, and is from Millac, near Nontron, France; stated by Kenngott to adhere to the tongue.

2. *Stolpenite* is a clay from the basalt of Stolpen. *Steargillite* is white, yellow, and pistachio-green, subtranslucent, insoluble in acids; and is easily cut into cakes looking like soap or wax; fr. near Virolet on the Rochelle railroad, and at the tunnel of Poitiers. *Saponite* of Nicklès is a white, plastic, soap-like clay from the granite from which issues one of the hot springs of Plombières, France, called *Soap Spring;* it was named *smegmatite* by Naumann. Nicklès obtained: $SiO_2$ 42·3, $Al_2O_3$ 19·2, $H_2O$ 38·5 = 100.

*Erinite* is a yellowish red clayey mineral from the Giant's Causeway; G. = 2·04; opaque; a little resinous in luster; unctuous; B.B. infusible, but whitens. Named from Erin (Ireland).

**Comp.**—Probably $H_2Al_2Si_4O_{12} + n$ aq. Chatelier, but analyses vary rather widely.

**Anal.**—1, 2, Salvetat & Damour, l. c. 3, Berthier [Tr. Ess. v. sèche **1**, 58], 5th Ed., p. 459. 4, Hauer, Jb. G. Reichs., **4**, 633, 1853. 5, Salvetat, l. c. 6, Rg., Pogg., **47**, 180, 1839. 7, Meillet, l. c. 8, Thomson, l. c. 9, Le Chatelier, Bull. Soc. Min., **10**, 209, 1887. 10, Helmhacker, Min. [a] MnO. [b] FeO. [c] At 250°, 16·7 p. c. [d] At 100°, 2·97 p. c.

The material of anal. 11 contained 2·28 p. c. apatite; that of anal. 10 had G. = 2·172 with 10·54 hygr. $H_2O$, and G. = 2·520 when dried over sulphuric acid.

Salvetat observes that sodium carbonate separates a little gelatinous silica, and sulphuric acid some quartz-silica—a fact of great interest in connection with the earthy hydrous aluminous silicates generally.

**Pyr., etc.**—B.B. infusible, excepting the stolpenite, which affords a yellowish enamel, probably owing to the 4 p. c. of lime in the state of silicate present as impurity. Montmorillonite loses 6 p. c. of water at 100° C., and delanouite 14 p. c.

*Severite*, according to the analysis of Pelletier (p. 688), would be identical nearly with the mineral from Confolens.

**Obs.**—Occurs as an alteration-product at the localities mentioned above.

Also in the U. S., at Branchville, Conn., in a soft pink form in a vein of albitic granite, probably due to the alteration of spodumene.

RAZOUMOVSKYN. Razoumoffskin *John*. A greenish white clay-like mineral from Kosemütz, in Silesia, near montmorillonite, except in the less amount of water. Zellner obtained, Schwgg. J., **18**, 340, 1816:

$SiO_2$ 54·50 $Al_2O_3$ 27·25 FeO 0·25 MgO 0·37 CaO 2·00 $H_2O$ 14·25 = 98·62

A similar bluish or greenish clay from the old copper mines at Lading, west of Wolfsberg, in Carinthia, has been investigated by Helmhacker, Min. Mitth., **2**, 256, 1879. H. = 3. Fracture subconchoidal. G. = 2·022 air-dried, = 2·285 after losing 10·12 p. c. hygroscop. water, = 2·138 corrected for impurities.

Analyses.—1, Helmhacker, l. c. 2, Hofmann, ibid.

| | $SiO_2$ | $Al_2O_3$ | CuO | CaO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|
| | | | | | at 100° | above 100° | |
| 1. | 43·06 | 25·26 | 3·25 | 0·83 | 8·44 | 20·10 | = 100·94 |
| 2. | 41·94 | 25·55 | 5·77 | 1·80 | 9·35 | 15·16 | = 99·57 |

The material analyzed contained some calcite and azurite. The formula for 1 is $Al_2O_3.3SiO_2 + 6H_2O$, or dried at 100°, $+ 4H_2O$.

## 497. PYROPHYLLITE.

Pyrophyllit *Herm.*, Pogg., **15**, 592, 1829. Pyrauxit *Breith.*, Handb., 397, 1841. Agalmatolite or Pagodite pt.

Monoclinic? Not observed in distinct crystals. Foliated, radiated lamellar or somewhat fibrous; also granular to compact or cryptocrystalline; the latter sometimes slaty.

Cleavage: basal, eminent. Laminæ flexible, not elastic. Feel greasy. H. = 1–2. G. = 2·8–2·9. Luster of folia pearly; of massive kinds dull and glistening. Color white, apple-green, grayish and brownish green, yellowish to ochre-yellow, grayish white. Subtransparent to opaque. Optically −. Bx ⊥ cleavage. Ax. angle large, to 108°, Dx.

**Var.**—(1) Foliated, and often radiated, closely resembling talc in color, feel, luster, and structure; G. = 2·785 Berlin. (2) Compact massive, white, grayish, and greenish, somewhat resembling compact steatite, or French chalk; G. = 2·81–2·92 Brush; H. = 1·5–3. This compact variety, as Brush has shown, includes part of what has gone under the name of agalmatolite, from China; it is used for slate pencils, and is sometimes called *pencil-stone*.

**Comp.**—$H_2Al_2Si_4O_{12}$ or $H_2O.Al_2O_3.4SiO_2$ = Silica 66·7, alumina 28·3, water 5·0 = 100.

**Anal.**—1, Rg., Pogg., **68**, 513, 1846. 2, Sjögren, Öfv. Ak. Stockh., **5**, 110, 1848. 3, Walmstedt, ib., p., 111. 4, Brush, Am. J. Sc., **26**, 68, 1858. 5, Church, Ch. [a] FeO.

**Pyr., etc.**—Yields water, but only at a high temperature. B.B. whitens, and fuses with difficulty on the edges. The radiated varieties exfoliate in fan-like forms, swelling up to many times the original volume of the assay. Heated and moistened with cobalt solution gives a deep blue color (alumina). Partially decomposed by sulphuric acid, and completely on fusion with alkaline carbonates.

**Obs.**—Compact pyrophyllite is the material or base of some schistose rocks. The foliated variety is often the gangue of cyanite.

Pyrophyllite occurs in the Ural, between Pyschminsk and Berezov; at Westanå, Sweden; the Horrsjöberg in Elfdalen, with cyanite; near Ottrez in Luxembourg; Ouro Preto, Brazil, in foliated masses of considerable extent.

Also in white stellate aggregations in Cottonstone Mtn., Mecklenburg Co., N. C.; in Chesterfield Dist., S. C., with lazulite and cyanite; in Lincoln Co., Ga., on Graves Mtn.; in Arkansas, at the Kellogg lead mine, near Little Rock. The compact kind, resembling a slaty soapstone in aspect and feel, is found in large beds in Deep River, N. C., greenish to yellowish white in color; similar at Carbonton, Moore Co., N. C. In thin seams and as petrifying material in coal slates of Mahanoy City, Penn.

The compact pyrophyllite of Deep River, N. C., is extensively used for making slate pencils and resembles the so-called agalmatolite or pagodite of China, often used for ornamental carvings. The term agalmatolite, however, has been loosely used for a variety of minerals; it properly belongs to a kind of pinite (p. 622).

GÜMBELITE *F. von Kobell*, Ber. Ak. München, 1, 294, 1870.

In thin, short fibrous layers in clay slate. Color light greenish white. Translucent. Luster pearly. Soft and flexible. Analyses.—1, Kobell, l. c. 2, Gümbel, Min. Mitth., 2, 189, 1879.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | $K_2O$ | $Na_2O$ | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Nordhalben | | 50·52 | 31·04 | 3·00 | 1·88 | 3·18 | — | 7·00 | X[a] 1·46 | = 98·08 |

[a] Undecomposed mineral. [b] Incl. C.

In the closed tube yields water. B.B. exfoliates somewhat like pyrophyllite. Fuses at 4. Not acted upon by acid.

Found at Nordhalben near Steben, in Oberfranken. Also (anal. 2) as a petrifying material of coal plants in the Tarentaise.

A mineral similarly associated in Pennsylvania was found by Genth to be pyrophyllite (anal. 9, above). Gümbelite may be an impure pyrophyllite.

NEUROLITE *Thomson*, Min., 1, 354, 1836. According to T. S. Hunt (Rep. G. Can., 485, 1863) a quartzose variety of wood-like agalmatolite. Thomson gave: $SiO_2$ 73·00, $Al_2O_3$ 17·35, $Fe_2O_3$ 0·40, CaO 3·25, MgO 1·50, $H_2O$ 4·30 = 99·80. Hunt's analysis afforded:

$SiO_2$ 50·30 $Al_2O_3$ 32·60 FeO *tr.* MgO 1·20 $Na_2O, K_2O$ *undet.* $H_2O$ 6·50

It occurs at Stanstead, Province of Quebec, forming a belt 150 feet wide; in some places granular and nearly pure, in others schistose and containing quartz. A thin layer has a banded structure, ligneous in appearance, with a shiny satin luster. It is translucent, of a wax- or amber-yellow color; feel unctuous. Named from νεῦρον, a *string* or *tendon* in allusion to the fibrous structure.

BIHARITE *K. F. Peters*, Ber. Ak. Wien, 44 (1), 132, 1861.

Massive; fine granular or microcrystalline.

H. = 2·5. G. = 2·737, yellow var. Luster greasy, inclined to pearly. Color yellowish to green, brownish. Translucent to hardly subtranslucent. Feel a little greasy. Optically doubly refracting.

Analysis.—Soltész (l. c.), after removing 4·68 $CaCO_3$:

$SiO_2$ 41·74 $Al_2O_3$ 13·47 MgO 28·92 CaO 4·27 $K_2O$ 4·86 $H_2O$ 4·46 $Fe_2O_3, Na_2O$ *tr.* = 97·72

B.B. infusible or nearly so.

Occurs embedded in a fine granular limestone in the Biharberg, near Rezbánya in Hungary.

**498. ALLOPHANE.** Allophan *Stromeyer*, Gel. Anz. Gött., 1251, 1816. Riemannit *Breith.*, Hoffm. Min., **4** b, 182, 1817. Elhuyarit *Sack*, Schw. J., **65**, 110, 1832 (announced, not named), Jahrb. Min., 28, 1834 (mentioned, not described).

Amorphous. In incrustations, usually thin, with a mammillary surface, and hyalite-like; sometimes stalactitic. Occasionally almost pulverulent.

Fracture imperfectly conchoidal and shining, to earthy. Very brittle. H. = 3. G. = 1·85–1·89. Luster vitreous to subresinous; bright and waxy internally. Color pale sky-blue, sometimes greenish to deep green, brown, yellow, or colorless. Streak uncolored. Translucent.

**Comp.**—Hydrous aluminium silicate, $Al_2SiO_5 + 5H_2O$ = Silica 23·8, alumina 40·5, water 35·7 = 100. Some analyses give 6 equivalents of water = Silica 22·2, alumina 37·8, water 40·0 = 100.

Impurities are often present. The coloring matter of the blue variety is due to traces of chrysocolla, and substances intermediate between allophane and chrysocolla (mixtures) are not uncommon, see chrysocolla. The green variety is colored by malachite, and the yellowish and brown by iron. Allophane occurs at Richmond, Mass., mixed intimately with part of the gibbsite of that locality (Silliman).

**Anal.**—1, Rath, Pogg., **144**, 393, 1871. 2, E. F. Smith, Am. Ch. J., **5**, 272, 1883. See also Gamper, Vh. G. Reichs., 354, 1876; and for earlier analyses 5th Ed., p. 419.

| | | $SiO_2$ | $Al_2O_3$ | CuO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|
| 1. Dehrn | G. = 2·079 | 23·53 | 37·73 | — | 1·92 | 36·86 = 100·04 |
| 2. Allentown, Penn. | | 21·39 | 35·20 | — | 1·96[a] | 40·86 = 99·41 |

[a] $(Ca,Mg)CO_3$.

**Pyr., etc.**—Yields much water in the closed tube. B.B. crumbles, but is infusible. Gives a blue color with cobalt solution. Gelatinizes with hydrochloric acid.

**Obs.**—Allophane is regarded as a result of the decomposition of some aluminous silicate (feldspar, etc.); and it often occurs incrusting fissures or cavities in mines, especially those of copper and limonite, and even in beds of coal. It lines cavities in a kind of marl at Gräfenthal, near Saalfeld in Thuringia, where it was first observed, in 1809, by Riemann, and hence has been called *riemannite.* Found also at Schneeberg in Saxony; at Gersbach in the Schwarzwald; Petrow in Moravia, in a bed of limonite; Chotina in Bohemia, at a copper mine in alum slate; at Friesdorf, near Bonn, in lignite (the *elhuyarite*, of a brownish or honey-yellow color, with G. = 1·6); Visé in Belgium, in the Carboniferous limestone; at the Chessy copper mine, near Lyons, France; in the chalk of Beauvais, France, presenting a honey-yellow color; at New Charlton, near Woolwich, in Kent, England, in old chalk-pits, of amber-yellow, ruby-red, and nearly opaque white colors.

In the United States it occurs in a mine of limonite, with gibbsite, at Richmond, Mass., forming a hyaline crust, scaly or compact in structure, and brittle; at the Bristol Copper Mine, Ct.; at Morgantown, Berks Co., Pa.; at the Friedensville zinc mines, Pa.; in the copper mine of Polk Co., Tenn.

Named from *ἄλλος, other*, and *φαίνεσθαι, to appear*, in allusion to its change of appearance under the blowpipe.

A yellowish white earthy mineral from Kornwestheim, between Stuttgart and Ludwigsburg, with G. = 1·794 and 2·098, consists of allophane and aluminite, and has been called *Kieselaluminite* (*Siliceous aluminite*) by Groningen and Oppel. In one of their analyses they obtained (JB.Ch., 892, 1852, from Württemb. Nat. Jahreshefte, 189, 1851): $SiO_2$ 13·06, $SO_3$ 5·04, $Al_2O_3$ 42·59, ign. 39·32 = 100·01. The *sulfatallophan* of Muck (Zs. Berg.-Sal. Wesen, **28**, 192, 1880) is similar; it occurs as an earthy, white or pale wine-yellow to greenish yellow substance in the clay of the Schwelm mine.

*Plumballophane* is a variety of allophane in stalactitic forms containing a little lead; from Monte Vecchio, Sardinia, Bombicci [Att. Soc. Ital. Sc. Nat., **11**], Jb. Min., 750, 1868.

CAROLATHINE *F. L. Sonnenschein*, Zs. G. Ges., **5**, 223, 1853 and J. pr. Ch., **60**, 268, 1853. Amorphous, with a mammillary surface, and approaching allophane in the ratio of Si to Al, but contains less water. H. = 2·5; G. = 1·515; color honey- to wine-yellow; subtranslucent.

Analysis by Sonnenschein gave: $SiO_2$ 29·62, $Al_2O_3$ 47·25, $H_2O$ 15·10, C 1·33, H 0·74, O 5·96 = 100.

B.B. ignites without flame, owing to the organic ingredients present. From the coal-bed of the Königin-Louise Mine, at Zabrze, in Upper Silesia. Named for Prince von Carolath.

SAMOITE *Dana*, Min., 288, 1850; and Geol. Rep. Expl. Exp., 324, 1849.

Stalactitic, with a lamellar structure. H. = 4–4·5. G. = 1·7–1·9. Luster resinous in the fracture. Color white, grayish, or yellowish. Translucent to subtranslucent, not adhering to the tongue nor plastic, being too hard.

Comp.—Perhaps $2Al_2O_3.3SiO_2.10H_2O$ = Silica 31·9, alumina 36·2, water 31·9 = 100.

Analyses.—1, 2, B. Silliman, l. c. 3, Janovsky, quoted by Zepharovich, Ber. Ak. Wien, **69** (1), 32, 1874.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $H_2O$ | $CaCO_3$ | |
|---|---|---|---|---|---|---|---|
| 1. *Samoite* | G. = 1·69–1·813 | 31·25 | 37·21 | — | 30·45 | 0·01 | MgO 0·06, $Na_2O$ 0·06 = 99·04 |
| 2. " | G. = 1·894 | 35·14 | 31·95 | — | 30·80 | 1·21 | MgO 1·05 = 100·15 |
| 3 *Pseud.* | G. = 1·87 | 29·12 | 31·46 | 8·86 | 30·56 | — | = 100 |

Gelatinizes in acids, leaving a portion of silica.

Forms stalactites and stalagmites; the former low conical; the latter flattened hemispherical in shape, with a width of 3 inches or so, smooth at surface. They consist within of a series of thin plates closely adhering. When fresh they were soft enough to be cut with a knife, but hardened on exposure. They occur in a lava cavern on the south side of the extinct volcanic island of Upolu, of the Navigator or Samoa group; the cavern was a passage some hundreds of yards long, entered about a mile and a half from the sea by a perpendicular descent of 25 feet, and extending toward and beneath the sea, and also up the mountain to an unascertained distance. Its sides and bottom were in places covered with the samoite, which had been formed from the percolating waters. The overlying rock was about 15 feet thick.

*Samoite* of Silliman, Jr. (Dana's Expl. Exp. Geol. Rep., 732), is a kind of feldspar incorrectly analyzed; probably labradorite.

The material of analysis 3 is an alteration-product of gehlenite from Orawitza, cf. Zepharovich, l.c. and this Min., p. 476.

**499. COLLYRITE.** Das man dort Salpeter nannte (fr. Schemnitz) *Freiesleben*, Lempe's Mag., **10**, 99, 1793. Natürliche Alaunerde (fr. Schemnitz) *v. Fichtel*, Min., 170, 1794; *Klapr.*, Beitr., **1**, 257, 1795. Kollyrit *Karst.*, Tab., 30, 73, 1800.

A clay-like mineral, white, with a glimmering luster, greasy feel, and adhering to the tongue. G. = 2–2·15. H = 1–2.

**Comp.**—$2Al_2O_3.SiO_2.9H_2O$; or 1 of allophane $6H_2O$ + 1 of gibbsite = Silica 14·1, alumina 47·8, water 38·0.

Analysis.—J. H. and G. Gladstone, Phil. Mag., **23**, 461, 1862.

Hove $SiO_2$ 14·49 $Al_2O_3$ 47·44 $H_2O$ [36·39] CaO 0·89 $CO_2$ 0·79 = 100

In other specimens Gladstone obtained from 8 to 3 p. c. of silica, indicating a varying proportion of aluminium hydrate. Early anals., see 5th Ed., p. 420.

**Pyr., etc.**—Yields water. B.B. infusible. Gives a blue color when heated with cobalt solution. Gelatinizes with nitric acid. Does not fall to pieces in water, or increase in weight.

**Obs.**—From Ezquerra in the Pyrenees; near Schemnitz, Hungary; near Weissenfels, Saxony; at Hove, near Brighton, England, in fissures in the upper chalk, of a pure white color and very soft.

The name *collyrium* (κολλύριον) was applied by the Greeks to the "Samian earth;" Kursten adopted it because the description of this earth by Dioscorides answers well for the above mineral.

DILLNITE *Haidinger, Hutzelmann*, Pogg., **78**, 577, 1849. A related substance; the gangue of the diaspore of Schemnitz, at a place called Dilln. It is probably a mixture of diaspore and kaolinite. See further 5th Ed., p. 421.

**500. SCHRÖTTERITE.** Opalin-Allophan *Schrötter*, Baumg. Ztg., **4**, 145, 1837. Schröttcrit *Glocker*, Grundr., 536, 1839. Opal Allophane.

Resembles allophane; sometimes like gum in appearance.

H. = 3–3·5. G. = 1·95–2·05. Color pale emerald- to leek-green, greenish white, yellowish, or at times spotted with brown. Translucent to nearly transparent.

**Comp.**—$8Al_2O_3.3SiO_2.30H_2O$ = Silica 11·7, alumina 53·1, water 35·2 = 100.

**Anal.**—1, Schrötter, J. pr. Ch., **11**, 380, 1837. 2, J. W. Mallet, Am. J. Sc., **26**, 79, 1858.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $H_2O$ | CaO | CuO | |
|---|---|---|---|---|---|---|---|---|
| 1. Styria | | 11·95 | 46·30 | 2·95 | 36·20 | 1·30 | 0·25 | $SO_3$ 0·78 = 99·73 |
| 2. Alabama | ⅔ | 10·53 | 46·48 | — | 41·09 | — | — | ZnO 0·77, FeO,MgO *tr.*, $SO_3$ 0·80=99·67 |

**Obs.**—From Dollinger mountain, near Freienstein, in Styria, in nests between clay-slate and granular limestone; in Cornwall; at the Falls of Little River, on the Sand Mtn., Cherokee Co., Alabama, as an incrustation over half an inch thick and partly stalactitic, resembling gum arabic when broken, having H. = 3·5, and G. = 1·974.

SCARBROITE *Vernon*, Phil. Mag., **5**, 178, 1829. A white clayey substance, allied to schrötterite in composition ($H_2O$ = 46·75 Vernon). It is dull, adhesive to moist surfaces and may be polished by the nail. It fills the veinings of a sandstone, which is much marked with oxide of iron, or of its septaria, on the coast of Scarborough, Yorkshire, England.

## APPENDIX TO CLAYS.

The following are other earthy hydrous aluminous silicates, all of doubtful character:

SINOPITE *Hausm.*, Handb., 1847; *Σινωπìς? Theophr.;* Rubrica *Vitruv.;* Sinopis *Pliny*, Sinopische Erde *Klapr.*, Beitr., **4**, 345, 1807; Bol de Sinopis *Beud.* A clayey earth of brick-red color dotted with white, adhering to the tongue. The material analyzed by Klaproth was from Anatolia, Asia Minor. The sinopic earth of the ancients was brought from Cappadocia, and used as a red paint, and may have been a red ocher. Theophrastus speaks of two other kinds of sinopic earth, one whitish, the other between the red and white in color, and called the pure kind because it was used without mixing; besides also an artificial kind made by burning a clay —the clay becoming red owing to the hydrated iron oxide present, which was freed from its water by the heat. Anal. 1, below.

MELINITE *Glocker*, Syn., 186, 1847; Gelb-Erde pt. *Wern.*, Hoffm. Min., **2**, b, 210; Argile ocreuse jaune pt. *H.*; Yellow ocher pt. A yellow clayey material, looking like yellow ocher, more or less lamellar in structure, shining in streak, adhering to the tongue, and soiling the fingers; G. = 2·24. The kind analyzed, and to which the name especially belongs, is that from Amberg in Bavaria. Other reported localities are Münden and Schoningen in Hanover; Wehrau, Prussia; Robschütz, Saxony; Vierzon (whence sometimes called *Vierzonite*), Dept. of Cher, and Pourrain, Dept. of Yonne, France. Anal. 2, below.

OCHRAN *Breith.*, Char., 100, 1832. A kind of "bole" of a yellow color from Orawitza, a little greasy in feel, with H. = 1–2, and G. = 2·4–2·5; streak pale yellow to colorless.

PLINTHITE. Plynthite *Thom.*, Min., **1**, 323, 1836. A brick-red clay from Antrim, Ireland, having G. = 2·342, and H. = 2·75, and not adhering to the tongue. Also from Quiraing in Skye, Heddle, Min. Mag., **5**, 26, 117.

Analyses.—1, Klaproth, l. c. 2, Kühn, Schw. J., **51**, 466, 1827. 3, Kersten, Schw. J., **66**, 31, 1832. 4, Thomson, l. c. 5, Heddle, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | NaCl | $H_2O$ |
|---|---|---|---|---|---|---|
| 1. *Sinopite* | 32·0 | 26·5 | 21·0 | — | 1·5 | 17·0 = 98·0 |
| 2. *Melinite* | 33·23 | 14·21 | 37·76 | — | — | 13·24 MgO 1·38 = 99·82 |
| 3. *Ochran* | 31·8 | 43·0 | 1·2 | — | — | 21·0 = 97 |
| 4. *Plinthite* | 30·88 | 20·76 | 26·16 | 2·60 | — | 19·60 = 100 |
| 5. " Skye | 29·55 | 19·03 | 28·01 | 2·23 | — | 17·39 FeO 3·25, MnO 0·84 = 100·30 |

These ocherous clays are probably only mixtures.

SMECTITE. Fuller's Earth pt.; Terra *or* Creta Fullonum pt.; Walkthon, Walkerde pt. *Germ.*; Terre à Foulon pt. *Fr.* Walker's Clay. Walkerite. Smectit *Breith.*, Handb., 344, 1841. Malthacit *Breith.*, J. pr. Ch., **10**, 510, 1837.

Massive. Clay-like. Very soft. G. = 1·9–2·1. Luster dull; of streak shining. Color white, gray, and various shades of green to mountain-green and olive-green, or brownish. Streak colorless. Unctuous. Does not adhere to the tongue. Softens in water.

*Fuller's Earth* includes many kinds of unctuous clays, gray to dark-green in color, and is only in part Breithaupt's smectite. Much of it is kaolinite. *Malthacite* is described as occurring in thin laminæ or scales and sometimes massive, with the color white or slightly yellowish, and thin plates translucent; the original is from basalt, at Steindörfel, in Lausitz; and Beraun in Bohemia is given as another locality. *Smectite* is a mountain-green, oil-green, and grayish green clay, from Cilly in Lower Styria.

The chemical species characteristic of these minerals is probably the same—a silicate of aluminium related to cimolite, but containing three or four times as much water.

Analyses.—1, Jordan, Pogg., **77**, 591, 1849. 2, Klaproth, Beitr., **4**, 338, 1807. 3, O. Meissner, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|
| 1. Cilly, *Smectite* | 51·21 | 12·25 | 2·07 | 4·89 | 2·13 | 27·89 = 100·44 |
| 2. Reigate, *Fuller's E.* | 53·00 | 10·00 | 9·75 | 1·25 | 0·50 | 24·00 $K_2O$ *tr.*, NaCl 0·10 = 98·60 |
| 3. Steindörfel, *Malth.* | 50·17 | 10·66 | 3·15 | — | 0·25 | 35·83 = 100·06 |

B.B. malthacite is infusible; but smectite and the Reigate fuller's earth, owing to the impurities present, fuse rather easily. Decomposed by hydrochloric acid.

RHODALITE *Thomson*, Min., **1**, 354, 1836, is a soft, earthy rose-red mineral; feel soapy. An impure hydrous silicate of iron and aluminium. From nodules in amygdaloid, in Antrim, northern Ireland.

SPHRAGIDITE. *Λημνία γῆ Dioscor. Σφραγὶς λήμνια.* Terra lemnia *Plin.*, **36**. Sphragid *Karst.*, Tab., 28, 88, 1808. Related in composition to cimolite (p. 689), but contains some alkali. Color yellowish gray, brownish, or yellowish white. Sometimes mottled with rust-like spots; harsh to the touch, adheres feebly to the tongue, and forms a paste with water.

Klaproth obtained for its composition, Beitr., **4**, 333, 1807: $SiO_2$ 66·00, $Al_2O_3$ 14·50, $Fe_2O_3$ 6·00, MgO 0·25, CaO 0·25, $Na_2O$ 3·50, $H_2O$ 8·50 = 99.

From Stalimene, the ancient *Lemnos*. It was also called *Terra sigillata*. It was dug for medicinal purposes once a year, cut into spindle-shaped pieces, and *stamped with a seal*, and hence the name *sigillata* in Latin, and *sphragis* in Greek. There was also a *Rubrica Lemnia*, or *Lemnian Reddle*, used by painters, which is confounded by Pliny with the true terra lemnia.

**Ehrenbergit** *Nöggerath*, Vh. Ver. Rheinl., **9**, 378, 1857. Near the preceding in composition, and, like that, containing alkali. It is almost gelatinous in the fresh state, and becomes fragile, pulverulent, and opaque on drying; color rose-red. Anal.—1, Schnabel, l. c. 2, G. Bischof, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | MgO | CaO | $Na_2O,K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| 1. | 56·77 | 15·77 | 1·65 | 0·86 | 1·30 | 2·76 | [3·78] | 17·11 = 100 |
| 2. | 64·54 | 6·04 | 4·56 | 4·61 | 0·41 | 3·96 | [8·11] | 7·77 = 100 |

*Ehrenbergite* occurs in clefts in trachyte at the quarries of Steinchen and Wolkenburg, Siebengebirge.

**Portite** *Meneghini & Bechi*, Am. J. Sc., **14**, 63, 1852. Orthorhombic. In radiated masses; cleavage very distinct parallel to a rhombic prism of 60° and 120°. H. = 5. G. = 2·4. Luster vitreous Color white. Opaque. Analysis by Bechi, l. c.: $SiO_2$ 58·12, $Al_2O_3$ 27·50, MgO 4·87, CaO 1·76, $Na_2O$ 0·16, $K_2O$ 0·10, $H_2O$ 7·92 = 100·43. B.B. intumesces much and affords a milk-white enamel. Dissolves in acids, even in the cold, and gelatinizes. From the gabbro rosso in Tuscany. Named after Mr. Porte of Tuscany.

**Teratolite** *Glocker*, Grundr., 544, 1839; Terra miraculosa Saxoniæ *C. Richter*, 1732; Saxonische Wundererde *of old Germ. authors;* Eisensteinmark *Breith.*, Char., 147, 1823, 301, 1832. A. Knop holds (Jb. Min., 546, 1859) that the teratolite is an impure lithomarge-like pholerite. It is described as having H. = 2–2·5, and G. = 2·49–2·5; color varied with lavender and other shades of blue, and spots of red, and rarely pearl-gray. It is from an amygdaloidal rock overlaid by coal strata at Planitz near Zwickau in Saxony. It contains much oxide of iron; but, according to Knop, probably is a mixture of pholerite with some free quartz, pulverized feldspar, hydrate of iron, carbonate of lime, and magnesia.

**Catlinite** *C. T. Jackson*, Am. J. Sc., **35**, 388, 1839; G. Catlin, ib., **38**, 138, 1840. The red clay forming beds of considerable extent in Pipestone county in the southwestern part of Minnesota. It was much used by the Indians for pipes, etc. It is not a definite mineral species. Anal.—1, 2, Peckham, 6th Ann. Rep. Minn., 101, 1877; cf. also ibid., p. 98, and 11th Rep., p. 7, 1883.

| | | | | | |
|---|---|---|---|---|---|
| 1. *Red* | $SiO_2$ 57·43 | $Al_2O_3$ 25·94 | $Fe_2O_3$ 8·70 | $H_2O$ 7·44 | MgO,CaO *tr.* = 99·51 |
| 2. *Light colored* | 58 25 | 35·90 | *tr.* | 6·48 | = 100·63 |

Named after the writer on the North American Indians, George Catlin (1796–1872).

**Keffekilite** Keffekilith *Fischer*, Mem. Soc. Nat. Moscou, **1**, 60, 1811. A pearl-gray to grayish white lithomarge, from the Crimea, having a greasy feel, and somewhat adhering to the tongue, with G. = 2·40. John. Becomes hard enough to scratch glass by calcination. It is evidently merely a clayey mixture.

*Keffekil Tartarorum* was, according to Cronstedt (Min., 79, 1758), a yellowish white lithomarge from Tartary, used there as a substitute for soap. It has been referred to sepiolite.

**Oravitzite** *Breith.*, Handb., 366, 1841. Massive and in nodules, and resembling halloysite, but heavier. H. = 2–2·5; G. = 2·701; luster waxy; color greenish white; unctuous. It is supposed to be a hydrous aluminous silica containing zinc oxide. In the glass tube yields much water. B.B. yields, according to Plattner, with soda and borax on charcoal, a slag which is yellow while hot and white on cooling. The zinc oxide is probably present as a mixture in the clay. From Orawitza, Hungary, with calamine.

**Hverlera** *Forchhammer*. Berz. JB., **23**, 265, 1844. A white or reddish clay resulting from the action of sulphuric and carbonic acids on the ferriferous clays of Krisuvig, Iceland. Analysis: $SiO_2$ 50·99, $Al_2O_3$ 7·39, $Fe_2O_3$ 21·21, MgO 19·96, $TiO_2$ 0·46 = 100·01.

**Wolchonskoite** *Kämmerer*, Jb. Min., **2**, 420, 1831. Volchonskoite.

Amorphous. Dull to shining. Color bluish green, passing into grass-green. Streak bluish green and shining. Feel resinous. Polished by the nail. Fracture subconchoidal. Adheres slightly to the tongue. Very fragile. H. = 2–2·5. G. = 2·2–2·3.

A chrome-bearing clay. Anal.—1, Kersten, Pogg., **47**, 489, 1839. 2, Ivanov, quoted by Kk., Min. Russl., **1**, 145.

| | $Si_2O$ | $Al_2O_3$ | $Cr_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. Okhansk | 37·01 | 6·47 | 17·93 | 10·43 | 1·66 | 1·91 | 21·84 | PbO 1·01, $K_2O$ *tr.* = 98·26 |
| 2. " | 36·84 | 3·50 | 18·85 | 17·85 | *tr.* | — | 22·46 | CaO 1·39 = 100·89 |

In the closed tube yields water. B.B. blackens, but is infusible. With the fluxes gives reactions for chromium and iron. Gelatinizes with hot concentrated hydrochloric acid, in which half the chromium is dissolved, the rest remaining in union with silica.

From Okhansk in Siberia.
Named after the Russian Volchonsky.

Miloschite. Miloschin *Herder*, Pogg., **47**, 485, 1839. Serbian *Breith.*, J. pr. Ch., **15**, 327, 1838.

Compact. H. = 1·5–2. G. = 2·131, Breith. Color indigo-blue to celandine-green. Approaches a *chromiferous allophane* with half the water of allophane. Analyses.—1, Kersten, Pogg., **47**, 485, 1839. 2, Bechi, Am. J. Sc., **14**, 62, 1852.

| | $SiO_2$ | $Al_2O_3$ | $Cr_2O_3$ | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. Rudniak | 27·50 | 45·01 | 3·61 | 0·30 | 0·20 | 23·30 | = 99·92 |
| 2. Tuscany | 28·36 | 41·33 | 8·11 | — | — | 22·75 | = 100·55 |

In a matrass yields water. B.B. infusible. Partly dissolved in hydrochloric acid.

From Rudniak in Servia, associated with quartz and brown iron ore; Volterra, Tuscany. Named after Prince Miloschi.

Selwynite *Ulrich* [Laboratory, **1**, 237, 1867] Contrib. Min. Victoria, 61. Massive. H.=3·5. G. = 2·53. Emerald-green. Subtranslucent. Fracture uneven and splintery. Somewhat brittle.

Composition, according to an analysis by Cosmo Newbery:

$SiO_2$ 47·15 $Al_2O_3$ 33·23 $Cr_2O_3$ 7·61 MgO 4·56 $H_2O$ 6·23 = 98·78

B.B. becomes white and fuses on the edges to a grayish white blebby glass. Only partially soluble in strong acids

Found near Heathcote, Victoria (Australia), in the Upper Silurian. Named after A. C. Selwyn, director of the geological survey of Victoria.

*Chrome Ocher.* A clayey material, containing some chromium oxide. Occurs earthy of a bright green shade of color.

Anal.—1, Drappiez. 2, Duflos, Schw. J., **64**, 251, 1832. 3, Zellner, Isis, 637, 1834.

| | $SiO_2$ | $Al_2O_3$ | $Cr_2O_3$ | $Fe_2O_3$ | $H_2O$ | |
|---|---|---|---|---|---|---|
| 1. Creuzat, Fr. | 64·0 | 23·0 | 10·5 | — | — | CaO and MgO 2·5 = 100 |
| 2. Halle | 57·0 | 22·5 | 5·5 | 3·5 | 11·0 | = 99·5 |
| 3. Silesia | 58·5 | 30·0 | 2·0 | 3·0 | 6·25 | = 99·75 |

Chrome ocher occurs at the localities above mentioned; also on Unst, one of the Shetlands, Mortenberg in Sweden, and elsewhere.

The *chrome ocher* of Halle, analyzed by Wolff (J. pr. Ch., **34**, 202, 1845), approaches selwynite in composition, but contains much more water. It afforded: $SiO_2$ 46·11, $Al_2O_3$ 30·53, $Cr_2O_3$ 4·28, $Fe_2O_3$ 3·15, $H_2O$ 12·53, $Na_2O$ 0·46, $K_2O$ 3·44 = 100·50; G. = 2·7, giving rather closely the formula of kaolin, and may be an impure kaolinite.

---

## V. Concluding Division.

| | | |

**501. CENOSITE.** Kainosit *A. E. Nordenskiöld*, G. För. Förh., 8, 143, 1886.

Orthorhombic or monoclinic; pseudo-hexagonal. Known only as a fragment of a six-sided prismatic crystal.

Cleavage: in one direction distinct; in two others, at 90° or nearly 90°, indistinct. Fracture uneven. H. = 5·5. G. = 3·413. Luster somewhat greasy. Color yellowish brown. Semi-transparent. Optically biaxial.

**Comp.**—$H_4Ca_2(Y,Er)_2CSi_4O_{17}$, which may be written $Ca(Y,Er)_2(SiO_3)_4.CaCO_3.2H_2O$ = Silica 34·7, carbon dioxide 6·4, yttrium oxides 37·6 (molec. wght. = 260·3), lime 16·1, water 5·2 = 100.

The true constitution is doubtful; Nordenskiöld calls attention to a possible relation to cancrinite, p. 427.

**Anal.**—Nordenskiöld, l. c.:

| | $SiO_2$ | $Y_2O_3$* | $Ce_2(La,Di)_2O_3$ | CaO | MgO | FeO | $Na_2O$ | $CO_2$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|
| | 34·63 | 37·67 | *tr.* | 15·95 | 0·03 | 0·26 | 0·40 | 5·90 | 5·26 = 100·10 |

* Incl. $Y_2O_3, Er_2O_3$, etc., molec. weight 260·3.

**Pyr.**—Gives off water at a low red heat and $CO_2$ on strong heating. B.B. fuses with difficulty to a white enamel. Dissolves slowly in cold acids, readily if heated, with the evolution of carbon dioxide.

**Obs.**—From Igeltjern on the island Hitterö, Norway; known only in a single specimen, the fragment of a large crystal resembling beryl.

Named from καινός, *unusual*, in allusion to the composition.

**502. THAUMASITE.** *A. E. Nordenskiöld*, C. R., 87, 313, 1878. *G. Lindström*, Öfv., Ak. Stockh., 35, No. 9, p. 43, 1878.

Tetragonal or hexagonal. Massive, compact, crystalline.

Cleavage in traces. Fracture subconchoidal. Brittle. H. = 3·5. G. = 1·877. Luster greasy, dull. Color white. Translucent. Optically uniaxial, negative. Refractive indices: $\omega = 1·503$, $\epsilon = 1·467$ Btd.[1]; $\omega = 1·507$, $\epsilon = 1·468$ Lévy-Lcx.[1]

**Comp.**—$CaSiO_3.CaCO_3.CaSO_4.15H_2O$ = Silica 9·6, carbon dioxide 7·1, sulphur trioxide 12·9, lime 27·0, water 43·4 = 100.

**Anal.**—1-3, Lindström, l. c. 4, Hedström, quoted by Widman, G. För. Förh., **12**, 20, 1890. 5, Widman, l. c.

| | G. | $SiO_2$ | $CO_2$ | $SO_3$ | CaO | $H_2O$ | $Al_2O_3$ | $Na_2O$ | $K_2O$ | Cl |

| 5. " | | 9·54 | 7·19 | 13·48 | 27·12 | 43·05 | — | — | — | — = 100·38 |

On the question of the nature of this remarkable mineral, cf. Törnebohm (quoted by Lindström); Btd., Bull. Soc. Min., **3**, 159, 1880, **4**, 8, 1881; Nd., G. För. Förh., **5**, 270, 1880, ib., **8**, 146, 1886; Cohen, Jb. Min., **2**, 22 ref., 1881; Lcx., G. För. Förh., **9**, 35, 1887, Btd., ib., p. 131. Thaumasite is shown to be essentially a homogeneous substance consisting for the most part of a negative uniaxial mineral with some amorphous matter, and small quantities of two minerals optically biaxial (Lcx., Btd.).

**Pyr.**—B.B. swells up, colors the flame red, but infusible. In salt of phosphorus a skeleton of silica. In the closed tube decrepitates and gives off much water.

**Obs.**—Occurs filling cavities and crevices at the Bjelke mine, near Åreskuta, Jemtland, Sweden; at first soft, but hardens on exposure to the air. Part of the specimens described by Nordenskiöld and Lindström were collected by A. Polheimer in 1802–05 (anal. 2), others in 1859 (anal. 1), and 1878 (anal. 3); that analyzed by Widman (5) is stated to have been collected in 1838 by Burman at Kjölland in the Kall parish, Jemtland, some 13 miles from the Bjelke mine. The identity of these several specimens is strong proof that the substance is a homogeneous mineral. Named from θαυμαζειν, *to be surprised*, in allusion to the remarkable composition, which is without parallel among minerals.

A fine fibrous chalk-white mineral occurs with the thaumasite, and is regarded as a decomposition product: H. = 1·5–2·5; analysis, Lindström: $SiO_2$ 11·85, $CO_2$ 6·86, $SO_2$ 13·31, CaO 25·74, $Al_2C_3(Fe_2O_3)$ 2·58.

**Ref.**—[1] Cf. references above, also Lévy-Lcx., Min. Roches, 286, 1888.

**503. URANOPHANE.** *Websky*, Zs. G. Ges., **5**, 427, 1853, **11**, 384, 1859. Uranotil *E. Boricky*, Ber. Böhm. Ges., 36, 1870.

Orthorhombic. In minute acicular prisms, in radiated or stellate aggregations. Also massive with fine fibrous structure.

H. = 2–3. G. = 3·81–3·90. Luster vitreous, of *b* pearly. Color honey-yellow, lemon- or straw-yellow.

**Comp.**—A hydrous silicate of uranium and calcium, $CaO.2UO_3.2SiO_2 + 6H_2O$ (Genth) = Silica 13·9, uranium trioxide 67·0, lime 6·5, water 12·6 = 100.

**Anal.**—1, Grundmann, Zs. G. Ges., **11**, 390, 1859; recalculated by Websky after deducting impurities (7 p. c.), ib., **22**, 92, 1870. 2, Boricky, l. c. 3, 4, Winkler, Jb. Min., **2**, 111, 1880. 5, Genth, Am. Ch. J., **1**, 88, 1879. 6, 7, H. von Foullon, Vh. G. Reichs., 21, 1883.

| 7. " " " | | 13·47 | 64·36 | — | 0·47 | 7·49 | 13·32 | = 99·11 |

A related mineral from the Garta feldspar quarry near Arendal, Norway, gave Nordenskiöld (approx.): $SiO_2$ 13·0, $ThO_2$ 3·5 (with Ce and Y), $UO_3$ 48·8, CaO 14·7, PbO 1·7, ign. 18·6=100·3. It is an alteration-product of cleveite, G. För. Förh., **7**, 121, 1884.

**Pyr., etc.**—B.B. turns dark and yields water. Soluble in warm hydrochloric acid with separation of flocculent silica.

**Obs.**—*Uranophane* (anal. 1) is from the granite of Kupferberg, Silesia; a prism of 34° and macrodome of 90° are mentioned. *Uranotil* (anal. 2–4) occurs at Wölsendorf, Bavaria, in cavities in quartz on fluorite with uraninite (a prism of 16° is mentioned). Also from the Weisser Hirsch mine at Neustädtel near Schneeberg, Saxony.

As an alteration-product of gummite (from uraninite) at the mica mines of Mitchell Co., N. C. (anal. 5–7); it forms an incrustation upon and penetrating the gummite.

Cyanochalcite *Hermann*, J. pr. Ch., **106**, 65, 1869.

Cryptocrystalline; often opal-like or enamel-like in texture; earthy. Incrusting or filling seams. Sometimes botryoidal.

Fracture conchoidal. Rather sectile; translucent varieties brittle. H. = 2–4. G. = 2–2·238. Luster vitreous, shining, earthy. Color mountain-green, bluish green, passing into sky-blue and turquois-blue; brown to black when impure. Streak, when pure, white. Translucent to opaque.

**Comp.**—True chrysocolla appears to correspond to $CuSiO_3 + 2H_2O$ = Silica 34·3, copper oxide 45·2, water 20·5 = 100, the water being double that of dioptase.

Composition varies much through impurities, as with other amorphous substances, resulting from alteration. As the silica has been derived from the decomposition of other silicates, it is natural that an excess should appear in many analyses. Impure chrysocolla may contain, besides free silica, alumina, black oxide of copper, oxide of iron (or limonite), and oxide of manganese; and consequently vary in color from bluish green to brown and black, the last especially when manganese or copper is present. Other kinds are impure with carbonate or sulphate of copper; and others with lead, antimony, arsenic, etc.

A kind from Dillenburg containing carbonate of copper has been called *dillenburgite;* another containing limonite is the *copper pitch-blende*, Kupferpecherz or Hepatinerz *Germ.* These are only mixtures.

An aluminous chrysocolla from Chili (anal. 7) has been called *pilarite* after Professor Pilar of Agram. Color greenish blue. G. = 2·62. A similar mineral from Utah has been examined by Santos, anal. 9.

*Demidovite* occurs at Tagilsk, Ural, in mammillated crusts of a sky-blue color. N. Nordenskiöld found in it 8·6 p. c. $P_2O_5$ (anal. 5). *Cyanochalcite* of Hermann from Nizhni Tagilsk is similar, containing 6·9 $P_2O_5$ Hermann (anal. 6). Massive, compact. H. = 4. G. = 2·79. Color azure-blue.

*Asperolite* of Hermann, with 27·25 p. c. $H_2O$, is made $CuSiO_3 + 3H_2O$; from Tagilsk, Russia; named in allusion to its brittleness. *Somervillite* is made by Berthier $CuSiO_3 + 4H_2O$, but on insufficient grounds; from Somerville, N. J. See Ann. Ch. Phys., **51**, 395, 1832, and 5th Ed., p. 403.

[c] X = PbO 0·41, ZnO 0·10, CaO 0·80, MgO 0·82.

**Pyr., etc.**—In the closed tube blackens and yields water. B.B. decrepitates, colors the flame emerald-green, but is infusible. With the fluxes gives the reactions for copper. With soda and charcoal a globule of metallic copper. Decomposed by acids without gelatinization.

**Obs.**—Accompanies other copper ores, occurring especially in the upper part of veins.

Found in most copper mines in Cornwall; at Libethen in Hungary; at Falkenstein and Schwatz in the Tyrol; in Siberia; the Banat; Thuringia; Schneeberg, Saxony; Kupferberg, Bavaria; South Australia; Chili, etc. In bluish green spherical forms in the lava at Monti Rossi, Etna.

In Somerville and Schuyler's mines, New Jersey, at Morgantown, Pa., and at Wolcottville, Conn., chrysocolla occurs associated with red copper ore, native copper, and green malachite; in Pennsylvania, near Morgantown, Berks Co.; at Perkiomen; at Cornwall, Lebanon Co.; also with similar associated minerals, and with brown iron ore, in Nova Scotia, at the Basin of Mines; also in Wisconsin and Michigan, mixed with carbonate of copper. In fine specimens, sometimes glassy green, at the Clifton mines, Graham Co., Arizona; also at the Old Globe mine, Gila Co., and at many other points. Emma mine, Utah

*Chrysocolla* is from χρυσός, *gold*, and κόλλα, *glue*, and was the name of a material used in soldering gold. The name is often applied now to borax, which is so employed. But much of the ancient *chrysocolla* was a green stone containing copper as the coloring ingredient, and the best, as Dioscorides says, was that which was κατακόρως πρασίζουσα, or of a fine leek-green or prase color; and the island of Cyprus, which was named from its copper mines, was a prominent locality. Pliny says the mineral was named after the real *chrysocolla*, because it looked like it. It may have included carbonate of copper, as was true to some extent of the *chrysocolla* and *mountain-green* of the 16th, 17th, and 18th centuries. The *cæruleum montanum* of Wallerius included both chrysocolla and an earthy variety of the carbonate.

KUPFERBLAU *G. Rose*, Reis. Ural, 1, 414, 1837. Bogoslovskite *Heddle*, Enc. Brit., **16**, 411, 1883. An impure copper silicate from the Bogovslosk, Ural. It yielded Rose $CO_2$ when treated with acid.

**505. CHLOROPAL.** *Bernhardi & Brandes*, Schw. J., **35**, 29, 1822. Unghwarit *Glocker*, Grundr., 537, 1839. Nontronite *Berthier*, Ann. Ch. Phys., **36**, 22, 1827. Pinguite *Breith.*, Schw J., **55**, 303, 1829. Fettbol *Freiesleben*, Mag. Orykt. Sachsen, **5**, 136. Gramenite *Krantz*, Ber. nied. Ges., Bonn, March, 1857; C. Bergemann, Jb. Min., 395, 1857. Graminite.

Compact massive, with an opal-like appearance; earthy.

H. = 2·5–4·5. G. = 1·727, 1·870, earthy varieties, the second a conchoidal specimen; 2·105, Ceylon, Thomson. Color greenish yellow and pistachio-green. Opaque to subtranslucent. Fragile. Fracture conchoidal and splintery to earthy. Feebly adhering to the tongue, and meagre to the touch.

**Var.**—*Chloropal* has the above-mentioned characters, and was named from the Hungarian mineral occurring at Unghwar, whence Glocker's name Unghwarite. It is described as breaking into parallelopipeds, having opposite magnetic polarity at opposite angles.

*Nontronite* is pale straw-yellow or canary-yellow, and greenish, with an unctuous feel; flattens and grows lumpy under the pestle, and is polished by friction; from Nontron, Dept. of Dordogne, France.

*Pinguite* is siskin and oil-green, extremely soft, like new-made soap, with a slightly resinous luster, not adhering to the tongue; the original from Wolkenstein in Saxony.

*Fettbol* has a liver-brown color, a slightly greasy luster, shining streak, conchoidal fracture, and G. = 2·249, Breith., and is from Halsbrücke near Freiberg.

*Graminite* has a grass-green color (whence the name), and occurs at Menzenberg, in the Siebengebirge, in thin fibrous seams, or as a feather of delicate lamellæ; H. = 1; G. = 1·87, after drying at 212° F.; luster and feel somewhat greasy, as in pinguite.

**Comp.**—A hydrated iron silicate, perhaps with the general formula $H_6Fe_2Si_3O_{12} + 2H_2O$ or $Fe_2O_3.3SiO_2.5H_2O$ = Silica 41·9, iron sesquioxide 37·2, water 20·9 = 100. Alumina is present in some varieties.

The water and silica both vary much. The Hungarian chloropal occurs mixed with opal, and graduates into it, and this accounts for the high silica of some of its analyses.

On the composition of this and related minerals, cf. Collins, Min. Mag., **1**, 70, 1876.

**Pyr., etc.**—Yields water. B B. infusible, but turns black and becomes magnetic. With the fluxes gives reactions for iron. Chloropal is partially decomposed by hydrochloric acid;

pinguite is completely decomposed, with separation of pulverulent silica, while nontronite gelatinizes with hydrochloric acid.

**Obs.**—Localities are mentioned above. The locality of *chloropal* at Meenser Steinberg is near Göttingen; *pinguite* occurs also at Sternberg in Moravia.

The Lehigh Mt , Pa., locality is south of Allentown, near Mountainville, where it occurs in connection with iron deposits.

Named from χλωρός, *green*, and *opal*.

Chloropal also occurs (Church, Ch. News, **2**, 71, 1866) in a feldspar quarry, near the old tin mine known as Carclase, not far from St. Austell, in Cornwall, associated with fluorite; it is the variety which has been named *graminite*.

GLASURITE. PROTONONTRONITE *A. Knop* [Vers. Oberrh. G. Ver. Stuttgart, 13, 1888], Zs. Kr., **18**, 668, 1891. Imperfectly characterized silicates occurring in amygdaloidal cavities in the limburgyte of Sasbach in the Kaiserstuhl. *Glasurite* is a brownish yellow substance mixed with calcium carbonate, etc., appearing in layers as a glazed coating of the cavities. After partial purification the results of analysis 1 were obtained.

*Protonontronite* is a dark leek-green substance which, mixed with calcium carbonate, forms a greenish white fatty mass filling the cavities entirely. Composition of material freed from the carbonate in analysis 2:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 51·20 | 8·29 | 19·62 | — | 0·25 | 4·04 | — | 16·80 | = 100·20 |
| 48·52 | 5·94 | — | 6 00 | 0·59 | 24·72 | 2·79 | 10·70 | = 99·26 |

ANTHOSIDERITE *Hausm.*, Gel. Anz. Gött., 281, 1841.

In tufts of a fibrous structure, and sometimes collected into feathery flowers. Resembles cacoxene. H. = 6·5. G. = 3. Luster silky, a little chatoyant on a fresh fracture. Color ocher-yellow and yellowish brown, somewhat grayish, rarely white. Powder brown to colorless. Opaque or slightly subtranslucent. Gives sparks with a steel. Tough.

Composition, $2Fe_2O_3.9SiO_2.2H_2O$ = Silica 60·3, iron sesquioxide 35·7, water 4·0 = 100. Analysis by Schnedermann (l. c., and Pogg., **52**, 292, 1841) of the yellow variety:

$\frac{2}{2}$ $SiO_2$ 60·08 $Fe_2O_3$ 34·99 $H_2O$ 3·59 = 98·66

B.B. becomes reddish brown, then black, and fuses with difficulty to a black magnetic slag. Decomposed by hydrochloric acid.

From Antonio Pereira, in the province Minas Geraes, Brazil, where it is intimately associated with magnetic iron. Named from ανθος, *flower*, and σίδηρος, *iron*.

**506. HISINGERITE.** Hisingerit (fr. Riddarhyttan) *Berz.*, Pogg., **13**, 505, 1828. Degeröit *Holmberg*, Bidr. Finl. Nat., 1, 4, Min. Ges. St. Pet., 1850, 1851, N. Nordenskiöld, Verz. Finl. Min., 1852. Skotiolit *Arppe*, Finsk. Min., 13, 1857. Manganhisingerite *Weibull*, Öfv. Ak. Stockh., **41**, No. 9, 21, 1884.

Amorphous, compact, without cleavage.

Fracture conchoidal. H. = 3. G. = 2·5–3·0. Luster greasy, inclining to vitreous. Color black to brownish black. Streak yellowish brown.

**Comp.**—A hydrated ferric silicate, but of uncertain composition, the material analyzed being in most cases of questionable homogeneity.

**Var.**—(1) *Hisingerite*, (2) *Degeröite*, G. = 2·54, Holmberg; H. = 2·5; color blackish green to black. (3) *Scotiolite;* G. = 3·09; H. = 3; color dark green to black (and named from σκότιος, *dark*); contains much magnesia, and less water than hisingerite.

*Manganhisingerite* from Vestra Silfberg, Sweden, anal. 14, is an alteration-product of knebelite, probably not homogeneous. G. = 2·469.

**Anal.**—1–10, Cleve, Öberg, Lindström, Nordenskiöld, Thoreld, Öfv. Ak. Stockh., **23**, 169, 1866. 11, Rg., Pogg., **75**, 398, 1848. 12, Thoreld, Öfv. Ak. [a] $Mn_2O_3$. [b] Chiefly but not wholly FeO. [c] Above 100°. [d] Also $P_2O_5$ 0·82.

A mineral from Ducktown, Tenn., pseudomorph after calcite, gave Genth: $SiO_2$ 24·42, $Fe_2O_3$ 49·02, ZnO 1·17, MgO 0·41, CaO 1·83, $H_2O$ 23·70 = 100·55 Am. Phil. Soc., **24**, 21, 1887.

**Pyr., etc.**—Yields much water. B.B. fuses with difficulty to a black magnetic slag. With the fluxes gives reactions for iron. In hydrochloric acid easily decomposed without gelatinizing.

**Obs.**—Found at the various localities mentioned above. At Riddarhyttan it occurs in reniform masses associated with pyrite in a copper mine, and is a result of alteration; at Degerö, near Helsingfors, Finland, in a silver mine.

Named after the Swedish chemist, W. Hisinger (1766-1852).

GILLINGITE. Svart Stenart (fr. Gillinge) *Hisinger*, Afh., **3**, 304, 1810. Gillingit *Hisinger*, Min. Geogr. Schwed. (Wöhler's), 102, 1826. Thraulit (fr. Bodenmais) *Kbl.*, Pogg., **14**, 67, 1828. Traulit.

Amorphous to compact. H. = 3. G. = 3·045, Gillinge, Hisinger. Luster shining to dull; surface of fracture earthy. Color black or blackish.

Anal.—1, Hisinger, Afh., **3**, 304. 2, Rg., Pogg., **75**, 400, 1848; also Hoglund and Tamm, Öfv. Ak. Stockh., **23**, 169, 1866. 3, Hermann, J. pr. Ch., **46**, 238, 1849. 4, Hisinger, Pogg., **13**, 505, 1828. 5, Kobell, l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. Gillinge | 27·50 | 5·50 | 52·27[a] | — | — | — | 11·75 | = 97·02 |
| 2. " | 32·18 | — | 30·10 | 8·63 | 4·22 | 5·50 | 19·37 | = 100 |
| 3. Orijärvi | 29·51 | — | 10·74 | 37·49 | 7·78 | — | 13·00 | = 98·52 |

| 5. " " | 31·28 | — | 43·42 | 5·70 | — | — | 19·12 | = 99·52 |

[a] Incl. 0·77 $Mn_2O_3$.

Yields much water. B.B. fuses at 5 to a black, slaggy, opaque, magnetic globule. Decomposed by hydrochloric acid.

From Gillinge mine, in Södermanland, Sweden, whence the name. *Thraulite* (named from θραυλός, *fragile*) occurs at Bodenmais, three leagues from Zwiesel, in Bavaria, with vivianite, etc.

JOLLYTE *Fr. v. Kobell*, Ber. Ak. München, 168, 1865.

Compact, amorphous. H. = 3. G. = 2·61. Luster weak, greasy. Color dark brown, with greenish powder. Analysis.—Kobell.

$SiO_2$ 35·55 $Al_2O_3$ 27·77 FeO 16·67 MgO 6·66 $H_2O$ 13·18 = 99·83

Occurs at Bodenmais in Bavaria, with pyrite, vivianite, iolite, etc. Resembles a hisingerite in which the iron is replaced by alumina. Named after the physicist, G. Jolly.

MELANOSIDERITE *J. P. Cooke*, Am. Ac. Sc., **10**, 451, 1875.

Amorphous; compact. H. = 4·5. G. = 3·391. Luster vitreous, inclining to resinous. Color black, with a tinge of red. Streak brownish to brick red. Subtranslucent.

If homogeneous, a basic hydrated iron silicate, having the formula $Fe_8SiO_{14}.6H_2O$ or $4Fe_2O_3.SiO_2.6H_2O$ = $SiO_2$ 7·4, $Fe_2O_3$ 79·2, $H_2O$ 13·4 = 100. Analysis.—W. H. Melville, ibid.:

⅔ $SiO_2$ 7·42 $Fe_2O_3$ 75·13 $Al_2O_3$ 4·34 $H_2O$ (above 100°) 7·68, 100° 6·17 = 100·74

In the closed tube decrepitates and gives off water. B.B. fuses at 4½ to a magnetic mass. Gelatinizes with hydrochloric acid.

Locality, Mineral Hill, Delaware Co., Penn. Named from μέλας and σίδηρος, in allusion to the black color.

Genth (2d Rep. Min. Pennsylvania, p. 216, 1876) suggests that melanosiderite is only a variety of an iron hydrate, probably a limonite. If the silica is an impurity the composition is exactly that of limonite, as Cooke remarks; he, however, regards it as a basic silicate on the ground of its vitreous luster, fusibility, definite composition, and the fact that it gelatinizes with acids.

Avasite *J. Krenner* [Földt. Értesitö, 2, 105, 1881], Zs. Kr., 8, 537, 1883. Occurs at the limonite deposits of the Avasthal, Comitat Szathmár, Hungary, and locally known as *Eisenpecherz.* Massive, black, but in thin splinters translucent, giving a red color. Fracture conchoidal, brittle. Luster vitreous. H. = 3·5. G. = 3·33.

Composition, according to Loczka, stated to be $5Fe_2O_3.2SiO_2.9H_2O$. Acetic acid dissolves the iron and leaves the silica in transparent colorless and glassy particles. Probably only a siliceous limonite.

---

**507. BEMENTITE.** *G. A. König*, Proc. Acad. Philad., 310, 1887.

In radiated stellate masses with small foliated structure; resembles some pyrophyllite.

Cleavage: perfect, and structure micaceous. Soft. G. = 2·981. Luster pearly. Color pale grayish yellow.

**Comp.**—Approximately $2MnSiO_3.H_2O$ = Silica 42·9, manganese protoxide 50·7, water 6·4 = 100.

**Anal.**—König, l. c.:

$SiO_2$ 39·00 MnO 42·12 FeO [3·75] ZnO 2·86 MgO 3·83[a] $H_2O$ 8·44 = 100

[a] CaO *trace.*

**Pyr.**—Fuses readily to a black glass; reacts for manganese with the fluxes. Water expelled above 100°. Dissolves in hot hydrochloric acid without gelatinization.

**Obs.**—Occurs closely associated with calcite at the zinc mines of Franklin Furnace, N. J.

Named after Mr. C. S. Bement of Philadelphia.

**508. CARYOPILITE.** Karyopilit *A. Hamberg*, G. För. Förh., **11**, 27, 1889.

Massive. In stalactitic and reniform shapes, compact within, the outer portions showing a concentric radiate-fibrous structure; forming a felted mass as seen under the microscope.

H. = 3–3·5. G. = 2·83–2·91. Color brown on the fracture. Double refraction weak. Extinction probably parallel.

**Comp.**—Approximately $4MnO.3SiO_2.3H_2O$.

**Anal.**—Hamberg, l. c. The material not entirely pure.

| $SiO_2$ | MnO | MgO | CaO | $H_2O$ | PbO | $Fe_2O_3$ | |
|---|---|---|---|---|---|---|---|
| 36·16 | 46·46 | 4·80 | 0·28 | 9·81[a] | 0·37 | 1·33 | $Al_2O_3$ 0·35, alk. 0·20, Cl 0·09 = 99·85 |

[a] Given off between 115° and a low red heat.

Easily soluble in strong acids.

**Obs.**—Occurs at the Harstig mine near Pajsberg, Wermland, Sweden, with crystallized native lead, sarkinite, brandtite.

Named from κάρυον, *walnut*, and πῖλος, *felt.*

**509. NEOTOCITE.** Neotokit *N. Nordenskiöld*, Verz. Finl. Min., 1852. Wittingit *id.*, ib. Vattenhaltigt Manganoxid-silikat *J. F. Bahr*, Öfv. Ak. Stockh., **7**, 240, 1850. Stratopeit *L. J. Igelström*, ib., 143, 1851 (with mention of "Neotokit" and "Wittingit").

Amorphous. H. = 3–4. G. = 2·64–2·8 Luster dull, sometimes feebly submetallic. Color black to dark brown and liver-brown. Streak dark brown to black. Opaque.

**Comp.**—A hydrated silicate of manganese and iron, but of very doubtful composition.

*Neotocite* is included by Nordenskiöld along with stratopeite, and good authority appears thus to be given for setting aside the older analysis of it by Igelström. In *stratopeite*, G. = 2·64, according to Igelström; in *neotocite* and *wittingite*, G. = 2·7–2·8, according to N. Nordenskiöld.

**Anal.**—1–4, Cleve and A. E. Nordenskiöld, Öfv. Ak. Stockh., **23**, 169, 1866. 5, Nordenskiöld, J. pr. Ch., **100**, 122, 1867 and l. c. 6, 7, Bahr, l. c.

[a] Above 100°.

**Pyr., etc.**—Yields much water. Reactions with borax for manganese and iron. Difficultly fusible to infusible.

**Obs.**—Occurs with rhodonite at Pajsberg, Filipstad, Sweden (*stratopeite*); Gestrikland (*neotocite*) in Sweden; at Ingoa (*ib.*), Finland; at Wittingi (*wittingite*) in Storkyro, Finland; at Bredvik (*ib.*) in West Gothland; at Klapperud in Dalecarlia.

Named from *νεότοκος*, *of recent origin.* This name antedates *stratopeite.*

A hydrated manganese silicate near neotocite and stratopeite from the Dillenburg mining region, Germany, has been investigated by A. Schneider, Jb. preuss. G. Landesanstalt, 472 *et seq.*, 1887. The manganese ore (Kieselmangan) is a heterogeneous mass varying from yellowish brown to reddish brown in color. It has been derived from the alteration of a silicate of manganese protoxide, which last appears in the ore in thin layers and kernels surrounded by reddish layers. H. = 3–4. G. = 2·465. Luster greasy. Color amber-yellow; streak yellow-brown. Doubly refracting. Optically biaxial, positive. Composition approximately given by anal. 1 by Bärwald, but the material not entirely pure. Anal. 2 gives the composition of dark red-brown portions, amorphous, H. = 4, G. = 2·675, mixed with limonite, calcite, etc.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | CaO | MgO | $H_2O$ | $CO_2$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 35·64 | 2·59 | 3·02 | 39 26 | 1·75 | 1·31 | 13·94 | 0·60 | alk. *undet.* = 98·11 |
| 2. | 30·21 | 2·30 | 12·49 | 29·16 | 6·04 | 0·98 | 16·62 | 2·40 | = 100·20 |

Klipsteinite is another hydrated manganese silicate, but impure. See p. 381. See also hydrorhodonite, p. 381, hydrotephroite, p. 458, epigenite or neotesite, p. 458.

**Penwithite** *J. H. Collins*, Min. Mag., **2**, 91, 1878; **3**, 89, 1879.

Massive. Fracture conchoidal. Brittle. H. = 3·5. G. = 2·49. Luster vitreous. Color dark amber to reddish brown. Transparent. Analysis:

$\frac{3}{8}$ $SiO_2$ 36·40 MnO 37·62 FeO 2·52 $H_2O$ 21·80 $MnO_2$ *tr.* $U_2O_3$ 0·30 Cu *tr.* = 98·64

Formula $MnSiO_3 + 2H_2O$. B.B. fuses with difficulty. Occurs with quartz and rhodochrosite in the district of Penwith (whence name), West Cornwall.

## APPENDIX TO HYDROUS SILICATES.

**Allophite** *Websky*, Zs. G. Ges., **25**, 399, 1873.

In dense, micro-crystalline masses, on fracture dull, and easily polished to a greasy luster by the hand. G. = 2·641 Leffler. Color pale grayish green. In appearance very similar to pseudophite; distinguished from serpentine by inferior hardness. Analysis.—Leffler, l. c.:

$SiO_2$ 36·23 $Al_2O_3$ 21·92 $Fe_2O_3$ 2·18 $Cr_2O_3$ 0·85 MgO 35·53 $H_2O$ 2·97 = 99·68

The water goes off only at a high temperature. Occurs at Langenbielau, Silesia; also at Reichenstein. From a quarry of limestone occurring in the gneiss.

**Antillite** *C. U. Shepard*, App. Cat. Meteorites, Amherst, Mass., 1872.

Massive and crystalline, presenting minute coppery laminæ with a fibrous cleavage. H. = 3·5–4. G. = 2·52. Color dark greenish brown. An analysis gave: $SiO_2$ 39·30, MgO 36·12, FeO 6·70, $H_2O$ 16·79, with traces of $Cr_2O_3$, CaO, $K_2O$ = 98·91. This composition approaches that of serpentine or deweylite.

**Aquacreptite** *C. U. Shepard*, Am. J. Sc., **46**, 256, 1868.

Massive, occurring in irregular polyhedral fragments, with flat or concave surfaces. H. = 2·5. G. = 2·05–2·08. Luster dull. Color yellowish brown. Streak orange-yellow. Brittle. Adheres to the tongue. Falls to pieces in water, with a crackling noise. Analysis.—J. H. Eaton, l. c.:

G. = 2·05 $SiO_2$ 43·03 $Al_2O_3$ 5·56 $Fe_2O_3$ 12·30 MgO 19·58 $H_2O$ 17·40 = 97·87

Decomposed by hydrochloric acid. Found in a vein in serpentine at West Chester, Pa.

**Arctolite.** Arktolite *Blomstrand*, "Ett högnordiskt mineral," G. För. Förh., **5**, 210, 1880.

Occurs in a crystalline limestone, forming small irregularly curved crystalline plates, generally compact, occasionally showing prismatic angles of 54°–56°, Sjögren. H. = 5. G = 3·03. Colorless or yellowish to greenish. Analysis:

| | $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| $\frac{2}{2}$ | 44·93 | 0·38 | 23·55 | 1·24 | 13·28 | 10·30 | 1·73 | 0·79 | 3·54 | = 99·74 |

This corresponds to $H_2O.(Ca,Mg)O.Al_2O_3.3SiO_2$. B.B. fuses with difficulty to a white enamel; partially attacked by acids with the separation of flocculent silica

Found in 1861 on Hvitholm, near Spitzbergen

**Balvraidite** *Heddle,* Min. Mag., **4**, 117, 1880.

Structure saccharoidal. H. = 6. G. = 2·91. Color pale purplish brown. Analysis of dark variety:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| 46·04 | 20·11 | 2·52 | 0·79 | 8·30 | 13·47 | 2·72 | 1·36 | 4·71 = 100·02 |

B.B. fuses with intumescence to a vesicular pale blue glass.

Occurs in a granular limestone at Balvraid, Inverness-shire, Scotland.

**Barettite** *Bombicci* [Atti della Soc. Ital. di Sc. Nat., **11**], Jb. Min., 750, 1868; Min., **2**, 773, 1875.

In nodular, radiated, and fibrous masses. H. = 2·5. G. = 2·5. Color apple-green. Streak white. Feel soapy. Analysis by Sestini: $SiO_2$ 30·96, $Al_2O_3$ 1·59, FeO 7·17, CaO 33·67, MgO 9·96, $CO_2$ 9·11, $H_2O$ 1·20, alkalies with $SO_3$ and $P_2O_5$ 6·34 = 100. From Traversella in the province of Ivrea.

**Bhreckite** or **Vreckite** *Heddle,* Min. Mag., **3**, 57, 1879.

Fine granular, scaly; soft and friable. Occurs as a light apple-green coating on quartz crystals. An analysis gave:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | CaO | MgO | $H_2O$ | alk. |
|---|---|---|---|---|---|---|---|---|
| 34·92 | 7·16 | 12·71 | 2·11 | 0·41 | 16·08 | 8·26 | 17·77[a] | *tr.* = 99·42 |

[a] 1·03 at 100° C.

Soluble in hydrochloric acid. From a cavity in a boulder of syenitic granite, found on the hill of Ben Bhreck, near Tongue, in Sutherland, Scotland.

**Bravaisite** *E. Mallard,* Bull. Soc. Min., **1**, 5, 1878.

In thin layers and schistose masses consisting of fine crystalline fibers, mostly parallel in position. Unctuous to the touch. Paste-like when wet. H. = 1–2. G. = 2·6. Color gray to greenish gray. Optically —. Extinction parallel. Double refraction strong; 2E = 40°. Analysis:

$SiO_2$ 51·4 $Al_2O_3$ 18·9 $Fe_2O_3$ 4·0 CaO 2·0 MgO 3·3 $K_2O$ 6·5 $H_2O$ 13·3 = 99·4

B.B. fuses easily to a white glass. In the closed tube gives off water and becomes brown. Partially attacked by acids.

Found in layers in the coal and bituminous schists of Noyant, Allier Dept., France. Named after the French crystallographer, M. Bravais. Starkl compares bravaisite with the *Weisserde* of Anna-Capelle and elsewhere in Austria, cf. p. 616, and Jb. G. Reichs., **33**, 654, 1883.

**Chonicrite.** Chonikrit *v. Kobell,* J. pr. Ch., **2**, 51, 1834.

Massive, crystalline granular, or compact. H. = 2·5–3. G. = 2·91. Luster weak silky, to glimmering or dull. Color white. Analysis, Kobell:

$SiO_2$ 35·69 $Al_2O_3$ 17·12 FeO 1·46 MgO 22·50 CaO 12·60 $H_2O$ 9·00 = 98·37

Fuses with intumescence at 3·5–4 to a grayish white glass, and is decomposed by hydrochloric acid, the silica separating in powder.

Forms, with pyrosclerite, seams in serpentine on Elba. Named from χωνεία, *fusion,* and κριτός, *test,* its fusibility distinguishing it from some allied minerals.

Stated by Groth to be essentially decomposed feldspar mixed with diallage.

**Davreuxite** *De Koninck,* Bull. Ac. Belg., **46**, 240, 1878.

In aggregates of slender laminæ appearing like acicular crystals; parallel extinction; resembles asbestus. Cleavage transverse. Color white with a tinge of flesh-red. Luster pearly. Analysis of material free from impurity, except quartz:

$\frac{3}{3}$ $SiO_2$ 55·94 $Al_2O_3$ 33·59 MnO 5·25 MgO 1·10 $H_2O$ 4·19 $Fe_2O_3$ or FeO *tr.* = 100·07

The amount of quartz was determined as from 13 to 18 p. c.; in the above analysis 16·63 p. c. Slightly attacked by acids. Occurs in quartz veins in the Ardennes schists, at Ottré, Belgium. Named after M. Ch. Davreux.

Lacroix shows that davreuxite is simply a hydrated mica. Optically —. 2E = 70°. Bx ⊥ cleavage (001). Bull. Soc. Min., **9**, 5, 1886.

**Dermatin** *Breithaupt,* Char., 104, 1832. Massive, reniform, or in crusts on serpentine, of a resinous luster and green color. Feel greasy; odor, when moistened, argillaceous. Apparently (5th Ed., p. 471) a hydrous silicate of iron and magnesium near deweylite, but probably a mixture. From Waldheim in Saxony. The name is from δέρμα, *skin,* alluding to its occurrence as an incrustation.

**Duporthite** *J. H. Collins,* Min. Mag., **1**, 226, 1877.

In fibrous masses occupying fissures in serpentine. H. = 2. G. = 2·78. Luster silky. Color greenish to brownish gray. Flexible in thin fibers like asbestus. Analysis gave:

| $SiO_2$ | $Al_2O_3$ | $FeO$ | $MgO$ | $CaO$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|
| 49·21 | 27·26 | 6·20 | 11·14 | 0·39 | 0·49 | 3·90 $H_2O$ hygroscopic 0·68 = 99·27 |

About half the water goes off only at an elevated temperature. From Duporth, near St. Austell, Cornwall.

**Ephesite** *J. L. Smith*, Am. J. Sc., **11**, 59, 1851, **48**, 254, 1869.

An alteration-product of corundum into fibrolite subsequently into potash mica, and containing more or less of the original mineral. From the emery locality at Gumuch-dagh near Ephesus.

*Lesleyite* of Lea (Proc. Ac. Philad., 44, 1867) from Unionville, Penn., is a similar mixture of damourite and corundum. Cf. S. P. Sharples, Am. J. Sc., **47**, 319, 1869, and later Genth, Am. Phil. Soc., **13**, 387, 1873.

**Forchhammerite** *Heddle*, Enc. Brit., **16**, 415, 1883.

Massive, granular. Luster subresinous to dull. Color dark green. Composition stated to be $FeSiO_3.6H_2O$. Färöer Is.

**Ginilsite** *Fischer*, *Rg.*, Min. Chem., 704, 1875; Zs. G. Ges., **28**, 236, 1876.

Massive. Color grayish yellow. G. = 3·404. Anal.—1, made in Rammelsberg's laboratory; 2, Rg., l. c.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $MgO$ | $CaO$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. | 38·75 | 4·83 | 16·32 | 9·48 | 26·52 | 3·73 | = 99·63 |
| 2. | 37·83 | 7·77 | 15·63 | 9·73 | 26·67 | 3·30 | = 100·93 |

Corresponds (Rg.) to $8(Ca,Mg)O.2(Fe,Al)_2O_3.7SiO_2,4H_2O$. Earlier analyses by Fellenberg and others, giving very different results (58 p. c. $SiO_2$, etc.) are discarded by Rammelsberg. B.B. fuses on the edges to a dark glass.

From Ginilsalp, Grisons, Switzerland.

**Groppite** *Svanberg*, Öfv. Ak. Stockh., **3**, 14, 1846.

Crystalline, with one distinct cleavage affording a broad cleavage surface, and two others less distinct. Fracture splintery. H. = 2·5. G. = 2·73. Thin splinters translucent. Color rose-red to brownish red. Streak paler. Analysis.—Svanberg, l. c:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $MgO$ | $CaO$ | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 45·01 | 22·55 | 3·06 | 12·28 | 4·55 | 0·21 | 5·23 | 7·11 insol. 0·13 = 100·13 |

In a matrass yields water. B.B. whitens, and on thin edges shows only incipient fusion. From a limestone at Gropptorp in Sweden.

Pisani found for a related mineral occurring in green grains in anhydrite, Bull. Soc. G., **22**, 25, 1864:

$SiO_2$ 48·20 $Al_2O_3$ 19.70 FeO 3·38 MgO 12·80 CaO 1·64 alk. [7·22] $H_2O$ 7·06 = 100

**Hydrosilicite** *Waltershausen*, Vulk. Gest., 305, 1853.

An amorphous substance or crust from Palagonia and Aci Castello, Sicily, which afforded:

| $SiO_2$ | $Al_2O_3$ | $MgO$ | $CaO$ | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| 44·90 | — | 4·60 | 33·32 | 2·11 | 1·86 | 13·21 | = 100 |
| 43·32 | 3·14 | 8·66 | 28·70 | 1·70 | | 14·48 | = 100 |

**Leidyite** *G. A. König*, Proc. Acad. Philad., 84, 1884.

In verruciform incrustations, consisting of fine scales with silky luster; also stalactitic; crystalline (?). H. = 1–2. Luster resinous. Color grass-, blue-, or olive-green. Streak white. Analysis:

$SiO_2$ 51·40 $Al_2O_3$ 16·82 FeO 8·50 MgO 3·07 CaO 3·15 $H_2O$ 17·08 = 100·02

B.B. fuses with intumescence to a light yellow green glass. In the closed tube gives off water and becomes brown. Soluble readily in hydrochloric acid, with partial gelatinization; after ignition insoluble.

Found with grossular garnet. zoisite, and quartz, at Leiperville, Delaware Co., Penn. Named after Dr. Joseph Leidy (1823–1891).

**Leucotile.** Leukotil *Hare*, Inaug. Diss. Breslau, 1879.

In fibers irregularly grouped on serpentine. Luster silky. Color green. Analysis:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $MgO$ | $CaO$ | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 28·98 | 6·99 | 8·16 | 29·78 | 7·37 | 1·32 | *tr.* | 17·29 = 99·89 |

Easily soluble in hydrochloric and sulphuric acids. B.B. fuses and becomes slightly yellow and yellowish brown. From Reichenstein, Silesia.

**Lillite** *Reuss*, Ber. Ak. Wien, **25**, 550, 1857. From Přibram, Bohemia, with pyrite, and arising, apparently, through the agency of decomposing pyrite. H. ≐ 2; G. = 3·043. Earthy, like glauconite; blackish green. Analysis afforded: $SiO_2$ 32·48, $Fe_2O_3$,FeO 54·95, $H_2O$ 10·20, $CaCO_3$ 1·96, $FeS_2$ 0·63 = 100·22.

**Melopsite** *Breith.*, Handb., **2**, 360, 1841. Melopsite is translucent, white, yellowish, grayish, or greenish, has a small conchoidal fracture, adheres a little to the tongue, and resembles in texture the flesh of an apple (whence the name from μῆλον, *apple*, and ὄψον, *meat, etc.*). According to Plattner, it consisted of silica, alumina, a little magnesia and iron oxide with ammonia, water, and some bitumen. An analysis by Goppelsröder (J. pr. Ch., **105**, 126, 1868) gave:

$SiO_2$ 44·15 $Al_2O_3$ 4·95 $Fe_2O_3$ 0·02 MgO 31·59 CaO 3·40 $H_2O$ 11·54(160°) $H_2O$ 4·02(ign.)=99·67

**Næsumite** *C. W. Blomstrand*, Öfv. Ak. Stockh., **25**, 209, 1868. A chalk-white mineral, from Näsum, Sweden. It occurs mixed with the phosphate attacolite. After calculating out the phosphoric acid the analysis gave:

$SiO_2$ 50·91 $Al_2O_3$ 27·86 $Fe_2O_3$ 1·36 MnO 0·36 CaO 13·82 $H_2O$ 4·39 = 98·70

**Nefedieffite.** Nefediewit *P. Pusirevsky*, Vh. Min. Ges., **7**, 15, 1872.

Amorphous, very similar to lithomarge. H. = 1·5. G. = 2·335. Fracture conchoidal. Color white to rose-red. Feel greasy. A hydrous silicate of aluminium and magnesium, but of doubtful composition. Analysis:

$\frac{3}{3}$ $SiO_2$ 60·76 $Al_2O_3$ 20·94 CaO 1·06 MgO 6·80 $Na_2O$ 0·40 $H_2O$ 9·92 = 99·88

This corresponds to $3H_2O.MgO.Al_2O_3.5SiO_2$. Scarcely soluble in acids.

Occurs with fluorite in limestone at Nerchinsk in Eastern Siberia.

**Neolite.** Neolith *Scheerer*, Pogg., **71**, 285, 1847.

In silky fibers stellately grouped; also massive. H. = 1–2. G. = 2·77, after drying. Color green. Luster silky or earthy. Composition uncertain; as the mineral is formed through the agency of infiltrating waters through rocks containing magnesia, it is not safe to assume that there are no impurities present. Anal.—1, 2, Scheerer, l. c. 3, Id., ibid., **84**, 375, 1851. 4, Richter, ib., p. 376.

| | $SiO_2$ | $Al_2O_3$ | FeO | MnO | MgO | CaO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|
| 1. Arendal | 52·28 | 7·33 | 3·79 | 0·89 | 31·24 | 0·28 | 4·04 | = | 99·85 |
| 2. " | 47·35 | 10·27 | 7·92 | 2·64 | 24·73 | — | 6·28 | = | 99·19 |

| 4. " | 51·44 | 8·79 | 0·88[a] | — | 31·11 | 2·00 | 6·50 | = | 100·72 |

[a] $Fe_2O_3$.

Occurs in the iron mines of Arendal, and in cavities in basalt near Eisenach. Also compact massive and earthy in fissures at Rochlitz in the Riesengebirge, Bohemia, of a pistachio-green color, or brownish; G. = 2·625 to 2·837. Named from νέος, *new*, and λίθος, *stone*.

**Nigrescite** *F. Hornstein*, Zs. G. Ges., **19**, 342, 1867.

Amorphous. Fracture uneven and splintery. H. = 2. G. = 2·845. Color, when fresh, apple-green; on exposure becomes gray to black; opaque and earthy, and, on drying, as light as wad. Loses 16·5 per cent hygroscopic water. Analysis:

$\frac{3}{3}$ $SiO_2$ 52·29 $Al_2O_3$ 5·14 FeO 15·71 MnO 0·23 MgO 18·11 CaO 2·59 $H_2O$ 6·29 = 100·36

Perhaps the product of the alteration of a magnesia-iron augite or amphibole.

Found in rounded masses in basalt, at Dietesheim, in the valley of the Main.

**Pelhamine** *C. U. Shepard*, Contr. Min., 1876. A serpentinous substance (altered asbestus) forming irregular seams and masses at the asbestus mine at Pelham, Mass., resembling a black serpentine. Color dark greenish gray. H. = 5. G. = 2·9–3·2. B.B. infusible. Analysis: $SiO_2$ 38·40, $Al_2O_3$ 2·80, FeO 15·52, MgO [39·88], $H_2O$ 3·40 = 100.

**Persbergite** *Igelström*, 1860, also Öfv. Ak. Stockh., **40**, No. 9, 91, 1883.

Occurs in red or grayish green bladed crystals embedded in granulyte at Persberg, Sweden. Analysis:

SiO 41·20 $Al_2O_3(Fe_2O_3)$ 27·50 MgO,CaO, etc. 18·22 $H_2O$ 13·08 = 100

Stated to be an alteration-product of nephelite.

**Picrofluite** *Arppe* Act. Soc. Fenn., **6**; Vh. Min. Ges., 148, 1852.

Amorphous. Luster greasy to dull. Color white, inclining to yellow and blue. H. = 2·5. G. = 2·74. Probably a mixture of fluorite with a magnesian silicate. Anal.—1, Galindo. 2, Arppe.

| | $SiO_2$ | FeO | MnO | MgO | CaO | $H_2O$ | F |
|---|---|---|---|---|---|---|---|
| 1. Lupikko | 29·00 | 1·54 | 0·78 | 28·79 | 22·72 | 8·97 | 11·16 = 102·96 |
| 2. " | 32 16 | 3·50 | — | 25·19 | 19·86 | 9·08 | *und.* |

B.B. fuses easily with intumescence. Completely soluble in acids; evolves silicon fluoride with sulphuric acid.

Occurs at Lupikko in Finland, some versts south of Pitkäranta, with chalcopyrite and sphalerite.

Picrosmine. Pikrosmin *Haidinger*, Min. Mohs., 3, 157, 1825.

A doubtful magnesian silicate. The mineral first described by Haidinger occurred with magnetic iron ore at the iron mine of Engelsberg, near Pressnitz in Bohemia. He mentions it as massive, with cleavages: perfect ‖ *b* (010), less so *a* (100), imperfect prismatic, 62° 11′. He further refers to a certain figure (25) as exhibiting these cleavage forms with one other form (*o*). On the strength of this statement Magnus and some later authors copied this figure (omitting the form named) as giving the crystalline form of picrosmine(!).

Haidinger also gives: H. = 2·5–3. G. = 2·66, cleavable massive; 2·596, columnar. Luster of cleavage-face pearly, elsewhere vitreous. Color greenish white; also dark green, gray. Streak white. Subtranslucent to opaque. Odor bitter argillaceous when moistened. Dx. obtained: double refraction strong; optical axes in the columnar variety in a longitudinal plane; bisectrix negative, normal to the sides of the columns.

Named from πικρός, *bitter*, and ὀσμή, *odor*. Haidinger instituted the species on the physical characters and cleavage of the massive and fibrous mineral, without a knowledge of the chemical composition, except blowpipe characters which suggested the presence of silica, magnesia, and water. He suggests that much of common asbestus may belong to it.

The original locality is mentioned above; the talcose or chloritic schist of Mt. Greiner in Tyrol, and the limestone of the vicinity of Waldheim, Saxony, have been reported as other localities. Des Cloizeaux obtained the above optical characters from the Pressnitz mineral, and also from another from Zermatt.

An analysis of the original mineral was made in 1826 by Magnus, Pogg., **6**, 53:

$SiO_2$ 54·89 $Al_2O_3$ 0·79 $Fe_2O_3$ 1·40 MnO 0·42 MgO 33·35 $H_2O$ 7·30 = 98·15

As corrected by Rg., this is: $SiO_2$ 54·88, $Al_2O_3$ 0·79, MgO 32·62, FeO 1·26, MnO 0·42, $H_2O$ 7·32 = 97·29.

This corresponds approximately to $H_2Mg_2Si_2O_7$ or $2MgO.2SiO_2.H_2O$, which has accordingly been accepted as the composition of not only picrosmine but also of such other substances as have with more or less reason been referred to it. The original mineral was doubtless a pseudomorph, and the species has a very uncertain claim to recognition. Most so-called picrosmine is simply serpentine.

Frenzel has given (Min. Mitth., **3**, 512, 1880) the following analyses of a mineral which he refers to picrosmine from the Plötzbachthal above Haslau near Zwickau. Structure columnar. H. = 3. G. = 2·80. Luster dull, greasy. Color greenish gray to green, but on the surface gray, brown to black.

| $SiO_2$ | $Al_2O_3$ | FeO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|
| 60·45 | 0·50 | 6·34 | 26·01 | 1·25 | 5·05 | = 99·60 |
| 59·80 | 0·12 | 6·30 | 25·18 | 3·30 | 5·40 | = 100·10 |

B.B. becomes white and fuses in thin splinters; gives the bitter odor like picrosmine.

Pihlite. Pihlit *Sefström*, Svanberg, Ak. H. Stockh., 155, 1839.

A white, micaceous mineral having about the same composition as the pseudomorphous cymatolite, and perhaps like that only a mechanical mixture of mica and feldspar—see under spodumene, p. 368. In granite at Brattstad, near Sala, Sweden.

Pilinite *A. von Lasaulx*, Jb. Min., 358, 1876.

In very minute (·005 mm. to ·01 mm.) prismatic crystals, having a rhombic section of about 120° and 60°; forming a fine felt-like mass, the needles often bent; resembles asbestus. Cleavage: basal, perfect; prismatic, distinct. G. = 2·263. Luster of needles silky. Colorless to white. Extinction parallel. Analysis, Bettendorf, l. c.:

$SiO_2$ 55·70 $Al_2O_3,Fe_2O_3$ 18·64 CaO 19·51 $Li_2O$ [1·18] $H_2O$ 4·97 $MgO,Na_2O,K_2O$ *tr.* = 100

Corresponds approximately to $CaO.Al_2O_3.5SiO_2.H_2O$. Fuses easily with strong intumescence to a sponge-like bead. Insoluble in acids, even on boiling.

Occurs with quartz, epidote, and stilbite in cavities in the granite of Striegau, Silesia. Named from πίλινος, *made of felt.*

Pilolite *Heddle*, Min. Mag., 2, 206, 1879.

A name given to some kinds of mountain cork, anals. 1–4, and mountain leather, anals. 5–7. Structure fibrous, more or less flexible and tough. Color white to pale buff, gray, etc. They occur at various localities in Scotland, in granular limestone, in granite veins, and in veins in sandstones and slates. Named from πῖλος, *felt.* Analyses.—Heddle, l. c., p. 217:

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | CaO | MgO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | above 100° | at 100° | |

The above agree approximately with $4MgO.Al_2O_3.10SiO_2.15H_2O$.

**Polyhydrite** *Breithaupt,* Handb , **2**, 334, 1841.

From St. Cristoph, at Breitenbrunn, in Saxony. Amorphous; H. = 2–3; G. = 2·095–2·142; luster dull; color liver-brown; streak lighter, grayish. According to Plattner contains $SiO_2$,$Fe_2O_3$,FeO, with some $Al_2O_3$,MnO, and 29·20 p. c. of water. Decomposed in hydrochloric acid.

**Pyknotrop** *Breithaupt,* Char., 110, 1832. An alteration-product related to serpentine, from Waldheim, Saxony. Cf. N.-Z., Min., 635, 1885.

**Pyroïdesine** *C. U. Shepard,* Cat. Meteorites, 1872. A substance near serpentine. The mean of two analyses gave: $SiO_2$ 42·45, MgO 33·07, FeO 6·85, $H_2O$ 16·40. De Regla, Cuba.

**Quincite** *Berthier.* In light carmine-red particles disseminated through a limestone deposit. Anal.—$SiO_2$ 54, FeO 8, MgO 19, $H_2O$ 17 = 98. From near the village of Quincy, France. Strong concentrated acid dissolves the magnesia and iron, and leaves the silica in a gelatinous state. The color is attributed to organic matter. Dufr. Min., **2**, 430, 1856.

**Restormelite** *A. H. Church,* J. Ch. Soc., **23**, 166, 1870. A massive grayish green agalmatolite-like mineral from Restormel Mine in Cornwall. H. = 2. G. = 2·58. Analysis:

$SiO_2$ 45·66 $Al_2O_3$ 35·10 FeO 1·11 MgO 0·85 $K_2O$ 2·30 $Na_2O$ 4·39 $H_2O$ 11·68 = 101·09

**Rubislite** *Heddle,* Trans. Soc. Edinb., **29**, 112, 1879.

A dark green compact granular or fine foliated aggregate. G. = 2·44. Analysis:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | CaO | MgO | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| 37·85 | 10·92 | 9·84 | 9·01 | 0·46 | 4·22 | 8·00 | 3·33 | 16·13 = 99·76 |

Completely decomposed by hydrochloric acid. B.B. fuses to a brown slag. From the granite of Rubislaw, near Aberdeen, Scotland.

**Stübelite** *Breithaupt,* B. H. Ztg., **24**, 322, 1865.

Reniform and botryoidal massive. Fracture conchoidal, distinct. Brittle. H. = 4–5. G. = 2·223–2·263. Luster vitreous, brilliant. Color velvet to pitchy black. Streak dark brown. Analysis by Stübel, l. c.:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | CuO | MgO | $H_2O$ | Cl |
|---|---|---|---|---|---|---|---|
| 26·99 | 5·37 | 10·18 | 21·89 | 15·25 | 1·03 | 16·85 | 0·77 = 98·33 |

Occurs at the island of Lipari. Named from Dr. Alphonse Stübel.

**Talcosite** *G. H. F. Ulrich,* Contrib. Min. Victoria, Melbourne, 1870.

In thin seams and threads with scaly structure. H. = 1–2. G. = 2·46–2·5. Luster pearly. Color silver-white, faint greenish, or yellowish. Scales flexible but not elastic. Resembles talc. Analysis, C. Newbery:

$\frac{3}{2}$ $SiO_2$ 49·04 $Al_2O_3$ 46·03 $H_2O$ 4·36 $Cr_2O_3$,FeO, etc. *tr.* = 99·43

Occurs with selwynite at Mount Ida near Heathcote, Victoria.

**Venerite** *T. S. Hunt,* Trans. Amer. Inst. Mng. Eng., **4**, 325, 1876.

Occurs as a greenish, earthy-looking "clay ore," in irregular layers in the schists connected with the magnetite of Jones mine, near Springfield, Berks Co., Penn. The purer portions have a pea-green or apple-green color when moist; become greenish white on drying, and fall to powder. Under the microscope is seen to consist mostly of minute, shining, transparent scales, with some impurities. Analysis by G. W. Hawes, on material purified by washing, gave:

| $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CuO | MgO | $H_2O$ | insol. |
|---|---|---|---|---|---|---|---|
| 28·93 | 13·81 | 5·04 | 0·27 | 16·55 | 17·47 | 12·08 | 6·22 = 100·37 |

After deducting the insoluble portion, this becomes: $SiO_2$ 30·73, $Al_2O_3$ 14·67, $Fe_2O_3$ 5·35, FeO 0·29, CuO 17·58, MgO 18·55, $H_2O$ 12·83 = 100. It is a heterogeneous substance, apparently a kind of chlorite impregnated with oxide of copper. Named in allusion to the alchemistic symbol for copper.

XYLOTILE *Glocker*, Synopsis, 97, 1847, *Bergholz*, of Sterzing, and *Holzasbest*.
Probably an altered asbestus. It occurs delicately fibrous; glimmering in luster; wood-brown, light or dark, and also green in color; with G. = 2·4–2·45 for the brown, and 2·56 for the greenish, Kenngott. Hauer finds (Ber. Ak. Wien, **11**, 388, 1853):

| | $SiO_2$ | $Fe_2O_3$ | FeO | MgO | CaO | $H_2O$ | | |
|---|---|---|---|---|---|---|---|---|
| 1. | 44·31 | 17·74 | 3·73 | 8·90 | 2·27 | 21·57 | = | 98·52 |
| 2. | 45·53 | 18·03 | 3·36 | 11·08 | *tr.* | 22·01 | = | 100·01 |
| 3. | 47·96 | 16·05 | 1·87 | 12·37 | *tr.* | 21·64 | = | 99·89 |

Of the water in the analyses, 9·20, 7·90, and 8·13 p. c. passed off at 100° C.; and, excluding the mean of these determinations, reduces the mean of the above results to $SiO_2$ 50·43, $Fe_2O_3$ 18·97, FeO 3·28, MgO 11·82, CaO 0·85, $H_2O$ 14·63 = 99·98. Kenngott considers it as probably altered chrysotile.

*Xylite* of Hermann is also probably only a hydrous asbestus. It has a brown color and asbestiform structure. Hermann obtained (J. pr. Ch., 34, 180, 1845): $SiO_2$ 44·06, $Fe_2O_3$ 37·84, CaO 6·58, MgO 5·42, CuO 1·36, $H_2O$ 4·70 = 99·96. H. = 3. G. = 2·935.

## TITANO-SILICATES, TITANATES.

510. **Titanite** $CaTiSiO_5$ Monoclinic
$\grave{a} : \dot{\bar{b}} : \dot{c} = 0·7547 : 0·8543 \quad \beta = 60° 17'$
511. **Keilhauite** $15CaTiSiO_5.(Al,Fe,Y)_2(Si,Ti)O_5$
Axial ratio like titanite.

512. **Guarinite** $CaTiSiO_5$ Orthorhombic
$\breve{a} : \bar{b} : \dot{c} = 0·9892 : 1 : 0·3712$
513. **Tscheffkinite**

514. **Astrophyllite** $(Na,K)_4(Fe,Mn)_4Ti(SiO_4)_4$ Orthorhombic
$\breve{a} : \bar{b} : \dot{c} = 0·9902 : 1 : 4·7101$

The following are closely related species, chiefly Titano-silicates of the cerium metals, calcium and sodium:

515. **Johnstrupite** Monoclinic $\grave{a} : \dot{\bar{b}} : \dot{c} = 1·6229 : 1 : 1·3911 \quad \beta = 86° 56'$
516. **Mosandrite** "
517. **Rinkite** " $\grave{a} : \dot{\bar{b}} : 5\dot{c} = 1·5688 : 1 : 1·4610 \quad \beta = 88° 47'$

518. **Perovskite** $CaTiO_3$ Isometric
519. **Dysanalyte** $6(Ca,Fe)TiO_3.(Ca,Fe)Nb_2O_6$ Isometric

This section includes a number of silicates which contain titanium, but whose relations are not altogether clear; also the titanate, Perovskite, and niobo-titanate, Dysanalyte, which is intermediate between Perovskite and the species Pyrochlore, Microlite, Koppite of the following chapter.

In general the part played by titanium in the many silicates in which it enters is more or less uncertain. It is probably in most cases, as shown in the preceding pages, to be taken as replacing the silicon; in others, however, it seems to play the part of a basic element; in schorlomite (p. 443) it may enter in both relations. Of the species which follow, Titanite is usually taken as a salt of meta-disilicic acid $H_2Si_2O_5$, in which one Si atom is replaced by Ti; it may, however, be regarded as a basic orthosilicate, $Ca(TiO)SiO_4$. The most satisfactory formula of Astrophyllite (see above) makes it an orthosilicate with the titanium as base, but with no clear relations to other species; if this view is maintained it would naturally be placed at the end of the section of orthosilicates (pp. 529 *et seq.*). Johnstrupite, Mosandrite, Rinkite are species of closely similar but complex composition. According to Brögger's view they are to be regarded as orthosilicates analogous to the epidotes to which they are related in form—they would then follow the Epidote Group, p. 526; Groth, however, suggests for them a metasilicate formula (the titanium replacing silicon) and a relation to the pyroxenes.

---

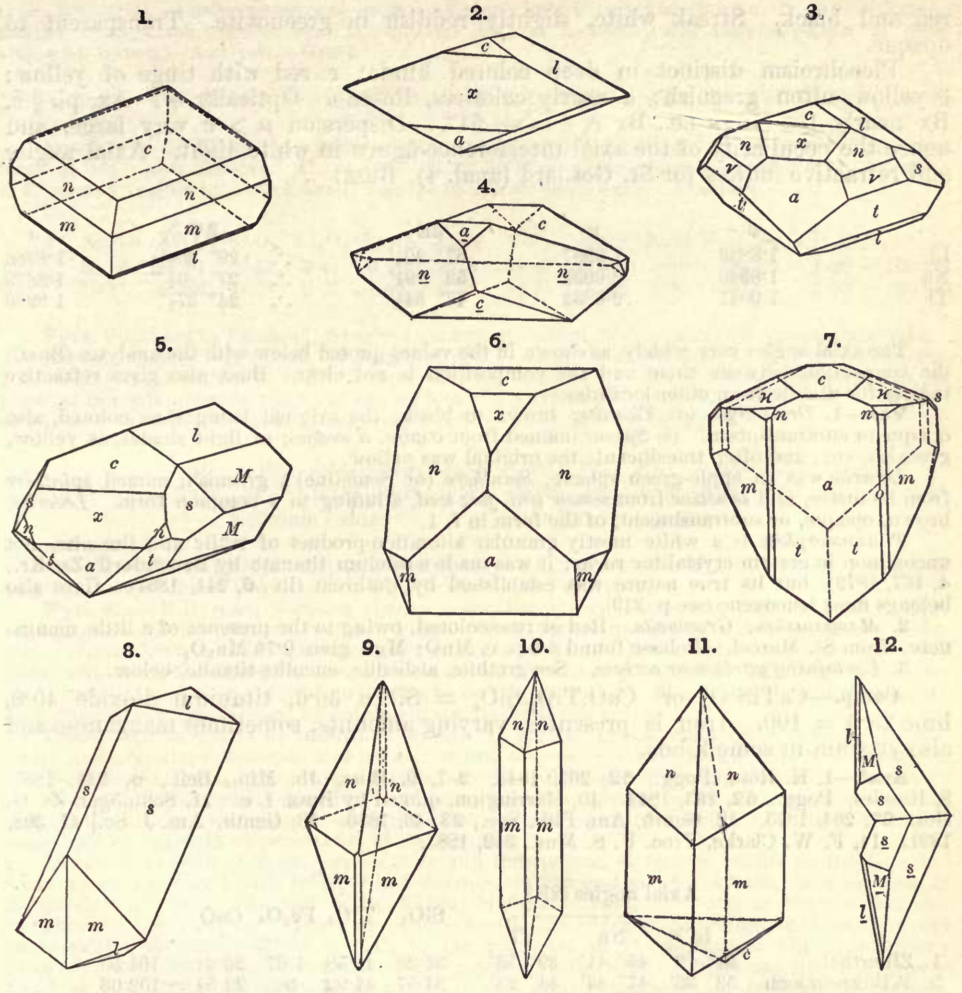

Fig. 1, *Lederite*, Diana, N. Y. 2, 5, after Rose. 3, Eisbruckalp, after Busz. 4, Nordmark, Flink. 7, Rothenkopf, Hbg. 8, *Pictite*, Dx. 9, 10, Norway, Bgr. 11, A. C. Lane. 12, Schwarzenstein, Hbg.

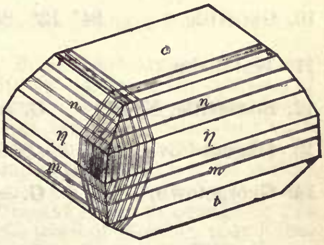
Twins: tw. pl. (1) *a* rather common, both contact-twins and cruciform penetration-twins; the former sometimes yielding forms apparently hemimorphic (f. 7). (2) *c* rather rare. (3) enclosed polysynthetic lamellæ[3], approximately ∥ *η* (221), f. 13, sometimes giving rise to easy parting. Crystals very varied in habit; often wedge-shaped and flattened ∥ *c*. Also prismatic by extension of *m* (110); less often *n* (111), f. 6; *s* (021), f. 8; again *l* ($\bar{1}12$) and *M* ($\bar{1}32$), f. 5, this the prismatic zone of Rose. Faces *a*, *l* ($\bar{1}12$) often striated ∥ their intersection with *m*; also *s* ∥ edge *p*/*s*. Sometimes massive, compact; rarely lamellar.

13.



Pitcairn, G. H. Williams[3].

Cleavage: *m* rather distinct; *a*, *l* ($\bar{1}12$) imperfect; in greenovite, *n* (111) easy, *t* ($\bar{1}11$) less so (Dx.). Parting[3] often easy ∥ *η* (221) due to twinning lamellæ. H. = 5–5·5. G. = 3·4–3·56; 3·541 Chester, Pirsson. Luster adamantine to resinous. Color brown, gray, yellow, green, rose-red and black. Streak white, slightly reddish in greenovite. Transparent to opaque.

Pleochroism distinct in deep colored kinds: $\mathfrak{c}$ red with tinge of yellow; $\mathfrak{b}$ yellow, often greenish; $\mathfrak{a}$ nearly colorless, Rosenb. Optically +. Ax. pl. ∥ *b*. Bx nearly ⊥ *x* (102), i.e., Bx $\wedge \dot{c} = +51°$. Dispersion $\rho > v$ very large, and hence the peculiarity of the axial interference-figure in white light. Axial angles and refractive indices for St. Gothard (anal. 4), Busz:

| | β | γ | 2E | | 2V | α |
|---|---|---|---|---|---|---|
| Li | 1·8839 | 1·9987 | 57° 20½′ | ∴ | 29° 30½′ | 1·8766 |
| Na | 1·8940 | 2·0093 | 52° 29⅜′ | ∴ | 27° 0⅛′ | 1·8879 |
| Tl | 1·9041 | 2·0232 | 47° 54⅜′ | ∴ | 24° 37½′ | 1·8989 |

The axial angles vary widely, as shown in the values quoted below with the analyses (Busz); the connection between them and the composition is not clear. Busz also gives refractive indices for titanite from other localities.

**Var.**—1. *Ordinary*. (*a*) *Titanite;* brown to black, the original being thus colored, also opaque or subtranslucent. (*b*) *Sphene* (named from *σφήν, a wedge*); of light shades, as yellow, greenish, etc., and often translucent; the original was yellow.

*Ligurite* was an apple-green sphene; *Spinthere* (or Semeline) a greenish; named *spinthère* from its luster, and *séméline* from *semen lini, flax-seed,* alluding to a common form. *Lederite*, brown, opaque, or subtranslucent, of the form in f. 1.

*Titanomorphite* is a white mostly granular alteration-product of rutile and ilmenite, not uncommon in certain crystalline rocks; it was made a calcium titanate by Bettendorff (Zs. Kr., **4**, 167, 1879), but its true nature was established by Cathrein (ib., **6**, 244, 1881). Here also belongs most leucoxene (see p. 219).

2. *Manganesian; Greenovite.* Red or rose-colored, owing to the presence of a little manganese; from St. Marcel. Delesse found 3·6 p. c. MnO; Mgc. gives 0·76 $Mn_2O_3$.

3. *Containing yttrium or cerium.* See grothite, alshedite, eucolite-titanite, below.

**Comp.**—$CaTiSiO_5$ or $CaO.TiO_2.SiO_2$ = Silica 30·6, titanium dioxide 40·8, lime 28·6 = 100. Iron is present in varying amounts, sometimes manganese and also yttrium in some kinds.

[a] FeO. [b] MnO.

GROTHITE is a titanite from the Plauen Grund near Dresden, investigated by P. Groth (Jb. Min., 44, 1866). Form and angles like titanite. Cleavage (parting) distinct. H. = 6·5;

G. = 3·52–3·60. Luster vitreous to greasy. Color clove to blackish brown; in thin splinters reddish brown and translucent. The altered mineral is earthy and isabella-yellow to pale yellowish brown. Analysis.—Groth:

$\frac{2}{2}$ $SiO_2$ 30·51 $TiO_2$ 31·16 $Fe_2O_3$ 5·83 $Al_2O_3 + Y_2O_3$ 2·44 MnO 1·02 CaO 31·34 = 102·30

ALSHEDITE of Blomstrand occurs in imperfect crystals with parting parallel $\eta$ (221), two faces at 54½°; also massive. H. = 3·36. G. = 5. Color pale brown to ash-gray. Opaque. B.B. readily fusible to a black bead; soluble in hydrochloric acid. Analyses:

| | $SiO_2$ | $TiO_2$ | $SnO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Y_2O_3$ | CaO | MnO | MgO | $K_2O,Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 28·26 | 36·61 | 0·47 | 3·41 | 4·25 | 2·78 | 21·06 | 0·98 | 0·48 | 0·70 | 1·20 = 100·20 |

From Slättkåra in Småland, Sweden; occurs embedded in the quartz of a pegmatyte vein.

*Eucolite-titanite.* A variety of titanite from Norway in crystals prismatic ∥ $\dot{c}$, often twins ∥ *a*; resembling eucolite in color, luster, etc., and shown by Brögger and Lindström to be peculiar in containing the metals of the cerium and yttrium groups. Bx $\wedge \dot{c} = +57°$. Dispersion $\rho > v$; strongly marked. Anal.—G. Lindström, quoted by Brögger:

| | $SiO_2$ | $TiO_2$ | $ZrO_2$ | $Ce_2O_3$ | $Y_2O_3$ | CaO | FeO | MgO | $Na_2O$ | $K_2O$ | ign. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| G. = 3·59 | $\frac{3}{3}$ 30·22 | 34·78 | 0·18 | 2·57[a] | 0·59[b] | 24·38 | 3·84 | 0·50 | 0·86 | 0·27 | 0·31 = 98·50 |

[a] Cerium oxides. [b] Yttrium earths.

Occurs with a whitish feldspar, elæolite, magnetite, spreustein, zircon, etc., on the island Stokö and elsewhere in the Langesund fiord; also from Fredriksvärn.

**Pyr., etc.**—B.B. some varieties change color, becoming yellow, and fuse at 3 with intumescence, to a yellow, brown, or black glass. With borax they afford a clear yellowish green glass. Imperfectly soluble in heated hydrochloric acid; and if the solution be concentrated along with tin, it becomes of a fine violet color. With salt of phosphorus in R.F. gives a violet bead; varieties containing much iron require to be treated with the flux on charcoal with metallic tin. Completely decomposed by sulphuric and hydrofluoric acids.

**Obs.**—Titanite occurs in embedded crystals, in granite, gneiss, mica schist, syenite, chlorite schist, and granular limestone; also in beds of iron ore, and volcanic rocks, and often associated with pyroxene, amphibole, chlorite, scapolite, zircon, apatite, etc. Microscopic examination shows it to be a common accessory constituent of many massive igneous rocks. In cavities in gneiss and granite, it often accompanies adularia, smoky quartz, apatite, chlorite, etc.; the crystals are sometimes coated with or penetrated by the chlorite.

Occurs in crystals of a pale green color and transparent, at various points in the Grisons, Switzerland, associated with feldspar and chlorite; in fine crystals at Tavetsch; in mica slate in the St. Gothard region; Zermatt in the Valais; Maderanerthal in Uri; also at Mont Blanc, and elsewhere in the Alps; on crystals of calcite at Chalanches and Maromme, in Dauphiné (the *spinthère* H.); in small reddish crystals in the protogine of Pormenaz and Chamouni (*pictite* Saus.); in large, broad, yellowish or reddish green crystals, with colorless apatite, in a talcose schist at Ala, Piedmont (*ligurite*); in pale yellowish green transparent or translucent crystals, lanceolate in form, lining fissures in titanic iron at Arendal, in Norway (*aspidelite* Weibye); with magnetite at Nordmark, Sweden; at Achmatovsk, Ural; at St. Marcel, in Piedmont, with manganesian epidote and romeine (*greenovite* Dufr.); at Val Maggia, Piedmont; at Schwarzenstein and Rothenkopf in the Zillerthal, Pfitsch, Pfunders, Tyrol; Felberthal in Pinzgau; with epidote and albite at Zöptau, Moravia, in crystals of varied habit; at Frugård, in Finland, of a brownish black color; in the syenite of Biellese, Italy (containing yttrium). Small crystals occur in syenite at Strontian in Argyleshire, near Criffel in Galloway; at Craig Cailleach in Perthshire; in Inverness; near Tavistock; near Tremadoc, in North Wales, with brookite; at Crow Hill, near Newry, Ireland.

Occasionally it is found among volcanic rocks, as at Lake Laach (*semeline* of F. de Bellevue), and at Andernach on the Rhine.

In *Maine*, in fine crystals at Sandford, also at Thurston. In *Mass.*, good crystals in gneiss, in the east part of Lee; at Bolton with pyroxene and scapolite in limestone; at Pelham; in honey-yellow crystals (G. = 3·541 Pirsson) with diaspore at Chester. In *Conn.*, at Trumbull. In *N. York*, at Roger's Rock on Lake George, abundant in small brown crystals, along with graphite and pyroxene; at Gouverneur, in black crystals in granular limestone with scapolite; in Diana near Natural Bridge, Lewis Co., in large dark brown crystals, among which is the variety *lederite* (f. 1); at Rossie, Fine, Pitcairn and Pierrepont, St. Lawrence Co., in pale red and brown crystals with apatite, pargasite, and feldspar; in Macomb near Pleasant Lake; in Orange Co., in large crystals abundant in limestone, near Duck-cedar pond, in the town of Monroe; near Edenville in light brown crystals in limestone; five miles south of Warwick, in large grayish brown crystals, with zircon, hornblende, and iron ore; also in small crystals a mile south of Amity; in Westchester Co., near Peekskill, in an aggregate of feldspar, quartz, and hornblende; also near

West Farms, in small reddish brown prisms; at Brewster, at the Tilly Foster iron mine in very fine transparent greenish crystals, sometimes 2 in. long, often twins, with magnetite, apatite, etc.; this occurrence (discovered in 1891) is similar to that at Nordmark, Sweden. In *N. Jersey*, at Franklin Furnace, of a honey-yellow color. In *Penn.*, Bucks Co., three miles west of Attleboro', associated with wollastonite and graphite; a small number of fine large crystals of a rich greenish brown tinge, in part symmetrical cruciform twins up to 2½ inches in length, have been found at Bridgewater Station, Delaware Co. In *N. Carolina*, at Statesville, Iredell Co., yellowish white with sunstone; also Buncombe Co., Alexander Co., and other points.

Occurs in *Canada*, in amber-colored crystals, in the granitoid trachytes of Yamaska, Shefford, and Brome Mts.; in clove- or chocolate-brown crystals, often large, at Argenteuil and Grenville, Argenteuil Co.; also Buckingham, Templeton, Wakefield, Hull, Ottawa Co.; at N. Burgess, of a honey-yellow, and N. Elmsley, Lanark Co.; near Eganville, Renfrew Co., Ontario, in very large dark brown crystals with apatite, amphibole, zircon; similarly at other points where apatite is abundant.

**Alt.**—Titanite occurs of little hardness, dull in luster, and hydrated from alteration. Crystals of this kind, found in a decomposing feldspar, with zircon at Green River, Henderson Co., North Carolina, have been named by C. U. Shepard (Am. J. Sc., **22**, 96, 1856) *Xanthitane*, see below.

Titanite (leucoxene, titanomorphite, see above and p. 219) is a not uncommon alteration-product of ilmenite and rutile. On the other hand rutile, octahedrite, and perovskite have been described as derived from the alteration of titanite.

**Artif.**—Formed in crystals by heating together $3SiO_2$, $4TiO_2$, and calcium chloride; also the manganesian (greenovite) by adding manganese chloride (Hautefeuille).

A stanno-silicate of calcium ($CaSnSiO_5$) corresponding to titanite has been obtained in monoclinic crystals by Bourgeois, Bull. Soc. Min., **10**, 54, 1887.

**Ref.**—[1] Min., 145, 1862; $\dot{c}$ here (Dx.) = $2\dot{c}$ Dana, Min., 1868; with Naumann, Hbg., etc., $a = 001$, $c = \bar{1}01$ ($y$), $m = 011$ ($r$), $x = \bar{1}02$, $n = \bar{1}23$; also for *hkl* (Dx.) and *pqr* (N.) we have: $h = \frac{p+r}{2}$, $k = \frac{q}{2}$, $l = -p$.

[2] For lists of forms, see Mlr., Min., 394, 1852, also Trans. Cambr. Phil. Soc., **7**, 210, 1842, or Pogg., **55**, 626, 1852; Dx., l. c., and **2**, XXIII, 1874; Hbg., Min. Not., **6**, 23, 1864; Zeph., Ber. Ak. Wien, **60** (1), 815, 1869; Hbg., l. c., **11**, 28, 1873; Busz, Jb. Min., Beil., **5**, 370, 1887 (who adds many new forms); Gdt., Index, **3**, 215, 1891. Cf. also Rose, Leonh. Taschenbuch, **2**, 393, 1821; Hbg., Min. Not., l. c., *et al.*; Zeph., Zillerthal, l. c.; Schrauf, Sulzbach, Ber. Ak. Wien, **62** (2), 704, 1870; Lewis, Phil. Mag., **3**, 455, 1877; Hintze, Zermatt, Zs. Kr., **2**, 310, 1878 (cf. Gdt., l. c., p. 222); Erem., Vh. Min. Ges., **16**, 254, 1881; Rath, Zs. Kr., **5**, 255, 1880; Flink, Nordmark. Ak. H. Stockh., Bihang, **12** (2), 2, 69, 1886. See also A. C. Lane, on the common forms of titanite in rocks, Min. Mitth., **9**, 207, 1887.

[3] On parting produced by twinning, Eremeyev, Jb. Min., 405, 1872; also l. c., and Zs. Kr., **5**, 500, 1881; G. H. Williams, Am. J. Sc., **29**, 486, 1885; Mügge, Jb. Min., **2**, 98, 1889. Mügge shows that the parting plane often deviates somewhat widely from $\eta$ (221). Light absorption measured photometrically, Pulfrich, Zs. Kr., **6**, 155, 1881.

XANTHITANE *C. U. Shepard*, Am. J. Sc., **22**, 96, 1856. *L. G. Eakins*, ibid., **35**, 418, 1888, and U. S. G. Surv., Bull. **60**, 135, 1890.

An alteration-product of titanite. Color light yellow, friable, mixed with impurities to an undetermined extent. It is called by Eakins a clay containing titanium in place of silicon. Analysis of material from Green river, Henderson Co., N. C., by Eakins:

| | $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $P_2O_5$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| G. = 2·941 | 1·76 | 61·54 | 17·59 | 4·46 | 0·90 | *tr.* | 4·17 | 9·92 = 100·34 |

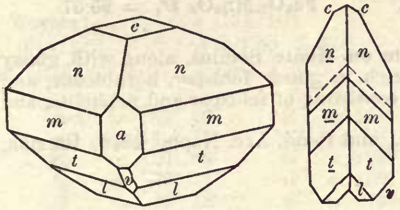
Material of analysis dried at 100°; the air-dried mineral loses 6·02 p. c. at 100°.

PYROMELANE *C. U. Shepard*, Am. J. Sc., **22**, 96, 1856, Min., 253, 1857. In angular grains from the gold-washings of McDowell Co., N. C. H. = 6·5; G. = 3·87; luster resinous; color reddish to yellowish brown and black; subtranslucent. B.B. infusible, but becomes black and opaque (whence the name); soluble in the fluxes, giving reactions of titanic acid and iron. Stated to be "essentially a titanate of alumina and iron with traces of lime and glucina," and "may contain zirconia also"; but the evidence of such a composition is not given. Probably only a variety of titanite.

CASTELLITE. Castellit *Breith.*, B. H. Ztg., **25**, 113, 1866. Monoclinic. In very small and exceedingly thin 8-sided tables, having for the angles of the rhombic prism 62°. Cleavage: prismatic? H. = 5·5–6. G. = 3·150. Luster vitreous, somewhat adamantine. Color wine-yellow to wax-yellow; streak colorless. Fragile. According to Plattner it acts B.B. like titanite, giving evidence of the presence of titanic acid, lime, and silica, but with less of the first and more of the last than in titanite. Occurs in the phonolyte of Holenkluk Mtn., near Proboscht, and in that of Sollodiz—a rock containing also sanidine, hornblende, augite, ilmenite, and apatite.

**511. KEILHAUITE.** Keilhauit *A. Erdmann,* Ak. H. Stockh., 355, 1844. Yttrotitanit *Scheerer*, Pogg., **63**, 459, 1844.

Monoclinic. In habit and angles near titanite.



Norway, Forbes.

**Forms:** *a* (100, *i-ī*), *c* (001, *O*); *m* (110, *I*), *v* (1̄01, 1-ī); *n* (111, − 1); *l* (1̄12, ½), *t* (1̄11, 1).

Forbes[1] measured: *am* = 33°, *av* = 55°, *cn* = 36° 30′. Cf. also angles for titanite, p. 712.

Cleavage: *n* quite distinct. H. = 6·5. G. = 3·52–3·77. Luster vitreous to resinous. Brownish black; in splinters brownish red and translucent; also dull brown and pale grayish brown. Streak-powder grayish brown to pale dirty yellow.

Optically +. Ax. plane ∥ *b* as in titanite. Axial angles, Busz[2]:

$2H_r = 60° 39'$ Li $\quad 2H_y = 58° 39'$ Na $\quad 2H_{gr} = 57° 28'$ Tl (in Monobromnaphtalin).
$2E_r = 112° 31'$ $\quad 2E_y = 108° 34'$ $\quad 2E_{gr} = 106° 37'$

**Comp.**—A titano-silicate of calcium, aluminium, ferric iron, and the yttrium metals.

Rammelsberg calculates for his analysis: $15CaSiTiO_5.(Al,Fe,Y)_2(Si,Ti)O_5$.

**Anal.**—1, 2, Rg., Pogg., **106**, 296, 1859. 3, Id., Min. Ch., Erg., 269, 1886. Also Erdmann, Forbes, 5th Ed., p. 387.

| | G. | $SiO_2$ | $TiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Y_2O_3$ | $Ce_2O_3$ | CaO | ign. | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Buö, *mass.* | 3·716 | 29·48 | 26·67 | 5·45 | 6·75 | 8·16 | | 20·29 | 0·54 | MgO 0·94, $K_2O$ 0·60 = 98·88 |
| 2. " *cryst.* | 3·773 | 28·50 | 27·04 | 6·24 | 5·90 | 12·08 | | 17·15 | 3·59 | = 100·50 |
| 3. Narestö, *mass.* | 3·57 | 30·81 | 36·63 | — | 1·12 | 6·27[a] | — | 25·03 | 1·13 | = 100·99 |

[a] At. weight 100·3.

**Pyr., etc.**—B.B. fuses with intumescence easily to a black shining glass. Yields an iron-colored glass with borax, which in the inner flame becomes blood-red. With salt of phosphorus gives an iron color and a silica skeleton, and in the inner flame a violet bead. Reaction for manganese with soda. Decomposed by hydrochloric acid.

**Obs.**—Occurs near Arendal, Norway; on the islands Buö, Askerö, Alve, and Narestö, in a feldspathic rock, both in crystals and massive. Crystals weighing 2½ lbs., and masses of 15 to 20 lbs., are mentioned by Forbes. A dull brown massive kind from Alve gave G. = 3·72; and a pale grayish brown 3·603; a specimen from near Narestö, G. = 3·519. The Alve keilhauite has two cleavages inclined to one another 42°. Also from Snarum, Norway.

Named after Prof. Keilhau of Norway.

**Ref.**—[1] Ed. N. Phil. J., **1**, 69, 1855; also Forbes and Dahll, Nyt Mag., **8**, 223, 1855. [2] Jb. Min., Beil., **5**, 342, 1887.

---

**512. GUARINITE.** *Guiscardi,* Rend. Acc. Napoli, Mem. **2**, 408, 1857, Zs. G. Ges., **10**, 14, 1858.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·9892 : 1 : 0·3712$ Lang-Guiscardi[1].

100 ∧ 110 = 44° 41⅓′, 001 ∧ 101 = 20° 36⅙′, 001 ∧ 011 = *20° 22′.

**Forms:** *a* (100, *i-ī*), *b* (010, *i-ĭ*), *c* (001, *O*); *g* (310, *i-3̄*), *f* (210, *i-2̄*), *m* (110, *I*), *d* (120, *i-2̆*), *k* (011, 1-ĭ), *q* (021, 2-ĭ).

Angles: *gg‴* = 36° 30′, *ff‴* = 52° 38′ *af* = *26° 19′, *mm‴* = 89° 23′, *dd′* = 53° 38′, *kk′* = 40° 44′, *qq′* = 73° 11′.

In minute thin tables, flattened ∥ *b* (010), nearly tetragonal in form.

H. = 6. G. = 3·487. Luster of cleavage-face somewhat adamantine. Color sulphur-yellow, honey-yellow, pale or dark. Streak uncolored, or whitish gray. Transparent to translucent. Ax. pl. ∥ *c*. Axial angle large, Dx.

**Comp.**—$CaTiSiO_5$ or $CaO.TiO_2.SiO_2$, same as for titanite = Silica 30·6, titanium dioxide 40·8, lime 28·6 = 100.

**Anal.**—Guiscardi, l. c.

$SiO_2$ 33·64 $TiO_2$ 33·92 CaO 28·01 $Fe_2O_3,Mn_2O_3$ *tr.* = 95·57

**Pyr., etc.**—Same as in titanite.

**Obs.**—Found in small cavities in a grayish trachyte on Monte Somma, along with glassy feldspar and nephelite. The mass of the trachyte is rich in glassy feldspar, hornblende, and melanite. In one case in the common rock of Somma, consisting of feldspar and nephelite, and here along with titanite.

**Ref.**—[1] Lang, Min. Mitth., 81, 1871; Guiscardi, l. c., and Rend. Acc. Napoli, 1876; Brezina, Min. Mitth., 285, 1874; Dx., Min., 2, xxiii, 1874.

**513. TSCHEFFKINITE.** ?Mineral de Coromandel *Beud.*, Tr., 2, 652, 1832. Tschewkinit *G. Rose*, Reis. Ural, 2, 1842.

Massive, amorphous.

H. = 5–5·5. G. = 4·508–4·549 G. Rose. Luster vitreous. Color velvet-black. Streak dark brown. Subtranslucent to opaque.

**Comp.**—Related to keilhauite, but uncertain. The mineral, as analyzed, seems to be in all cases an alteration-product, more or less heterogeneous, and the composition of the original mineral is as yet very uncertain.

Hermann makes thoria present in tscheffkinite from the Ural; Damour proved its absence in the Indian mineral.

Des Cloizeaux states that the latter consists of a brown material not acting on polarized light, and small colorless grains which are strongly doubly refracting. The mineral has H. = 5·5–6; G. = 4·26; luster vitreous, inclining to resinous; color brownish black, subtranslucent.

Cross found the mineral analyzed by Eakins to consist mainly of a reddish and yellowish brown transparent amorphous substance, probably the original mineral, traversed by cracks filled with a secondary reddish brown, opaque, ocherous matter; bands of secondary minerals, probably calcite and titanite, were also noted with others not identified.

**Anal.**—1, H. Rose, Pogg., **62**, 591, 1844. 2, Hermann, Bull. Soc. Moscou, **39** (1), 57, 1866. 3, Damour, Bull. G. Fr., **19**, 550, 1862. 4, R. C. Price, Am. Ch. J., **10**, 38, 1888. 5, 6, L. G. Eakins, Am. J. Sc., **42**, 36, 1891.

[a] $ZrO_2$. [b] Incl. 15·38 $Di_2O_3$, 4·96 $La_2O_3$. [c] $Na_2O$. [d] Incl. $Er_2O_3$, molec. wght. 308. [e] Do. 312.

**Pyr., etc.**—B.B. glows, then intumesces strongly, becomes brown, and fuses to a black glass. Gives with the fluxes reactions for iron, manganese, and titanium. Gelatinizes with hydrochloric acid. The Indian mineral in a closed tube yields a little water. B.B. fuses with intumescence to a black scoria, feebly magnetic. With salt of phosphorus it gives in R.F. a pale brown glass, opaline, which becomes milky in the O.F. With borax it affords a hyacinth-brown glass, transparent in the R.F. and pale brown and opaque in the O.F. Attacked readily by nitric acid, especially if heated, depositing gelatinous silica mixed with titanic oxide and black grains of titanic iron.

**Obs.**—From the Ilmen Mountains in the Ural; only a few specimens have been found; the tscheffkinite in collections is mostly *uralorthite* (p. 523), which it much resembles. Also from S. India, probably Kanjamalai Hill, Salem distr. (cf. Mallet, Rec. G. Surv. India, 25, 123, 1892).

An isolated mass weighing 20 lbs. has been found on Hat Creek, near Massie's Mills, Nelson Co., Virginia (anal. 4 by Price); also found, south of this point, in Bedford Co., in the same state (anal. 5, 6 by Eakins); at the latter locality it exists in some quantity as reported by H. M. Engle.

Named after the Russian general, Tschevkin (Chevkin).

**514. ASTROPHYLLITE.** Astrophyllit *Scheerer*, B. H. Ztg., **13**, 240, 1854.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0·99025 : 1 : 4·7101$ Brögger[1].

$100 \wedge 110 = 44° 43\frac{1}{6}'$, $001 \wedge 101 = 78° 7\frac{2}{3}'$, $001 \wedge 011 = 78° 0\frac{5}{6}'$.

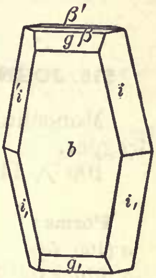
Crystals often elongated in the direction of *ć*; or elongated ‖ axis *ă* by development of the brachypinacoid (‖ cleavage). Faces strongly striated ‖ intersection-edge with *b*; *b* horizontally striated. Also lengthened into thin strips or blades; sometimes arranged in stellate groups.



Cleavage: *b* perfect; *c* very imperfect. Percussion-figure on a cleavage surface shows two rays crossing at angles of approx. 90° (81° to 85°), and nearly ‖ the dome 014. Laminæ brittle, not elastic like muscovite. H. = 3. G. = 3·3–3·4; 3·324 Pisani; 3·375, Colorado, Koenig. Luster submetallic, pearly. Color bronze-yellow to gold-yellow. Powder resembling that of mosaic gold. Translucent in thin leaves.

Pleochroism strong: 𝔠 lemon-yellow, 𝔟 orange-yellow, 𝔞 deep orange-red. Absorption 𝔞 > 𝔟 > 𝔠. Optically +. Ax. pl. ‖ *c*. $Bx_a \perp a$. $Bx_o \perp$ cleavage (*b*) or nearly so, but varying somewhat from secondary causes. Axial angles variable:

Norway $2H_{o.r} = 122° 18'$ Li $2H_{o.y} = 124° 52'$ Bkg. $2H_o = 114° 37\frac{1}{2}'–123° 28'$ Bgr.
Colorado $2H_{o.r} = 121° 38'$ Li $2H_{o.y} = 124° 14'$ $2H_{o.gr} = 125° 6'$ Tl Bkg.

Indices:

$\alpha = 1·678$ $\beta = 1·703$ $\gamma = 1·733$ $\gamma - \alpha = 0·055$ Lévy-Lcx.

**Comp.**—Perhaps (Bgr.) an orthosilicate $\overset{I}{R}_4\overset{II}{R}_4Ti(SiO_4)_4$ with $\overset{I}{R}$ = H,Na,K and $\overset{II}{R}$ = Fe,Mn chiefly, including also the $Fe_2O_3$. This formula is confirmed by Eakins.

**Pyr., etc.**—B.B. swells up and fuses easily to a black magnetic enamel. With soda or borax, a strong manganese reaction. Decomposed by hydrochloric acid with separation of silica in scales.

**Obs.**—Occurs on the small islands in the Langesund fiord, near Brevik, Norway, in zircon-syenite, embedded in lamellar feldspar, also in leucophanite and in natrolite (spreustein), and associated with catapleiite, ægirite, large prisms of black mica, and numerous other species. Similarly associated at Kangerdluarsuk, Greenland.

With arfvedsonite and zircon at St. Peter's Dome, Pike's Peak, El Paso Co., Colorado.

Named from *ἀστρον*, *star*, and *φύλλον*, *leaf*, in allusion to the stellate aggregation and foliated micaceous structure.

**Ref.**—[1] Zs. Kr., **16**, 200, 1890; the fundamenta. angles are taken as corrected by Brögger (letter of April 30, 1890), further the axes *a* and *b* are exchanged as required by the ratio obtained; the domes *β*, *g* cannot be taken as macrodomes unless the calculated ratio of the lateral axes is regarded as of no value.

The form was first made orthorhombic by Nordenskiöld (Öfv. Ak. Stockh., **27**, 561, 1870) and Des Cloizeaux (Min., **1**, 497. 1862), was later made monoclinic by Bücking, Zs. Kr., **1**, 433, 1877, and triclinic by Brögger, ibid., **2**, 278, 1878. Brögger finally (1890) shows, however, that the variation in angle and optical character earlier noted is probably without significance, being due to deformation produced by pressure.

---

### 515. JOHNSTRUPITE. *W. C. Brögger*, Zs. Kr., **16**, 74, 1890.

Monoclinic. Axes $\grave{a} : \bar{b} : \acute{c} = 1{\cdot}6229 : 1 : 1{\cdot}3911$; $\beta = 86° \, 55\frac{3}{4}' = 001 \wedge 100$ Brögger.

$100 \wedge 110 = 59° \, 19\frac{1}{3}'$, $001 \wedge 101 = 39° \, 17\frac{3}{4}'$, $001 \wedge 011 = 54° \, 15'$.

**Forms:**
*a* (100, *i*-ī)
*b* (010, *i*-ĭ)

*t* (710, *i*-7̄)
*k* (410, *i*-4̄)
*n* (310, *i*-3̄)
*l* (520, *i*-$\bar{\frac{5}{2}}$)

*f* (210, *i*-2̄)
*m* (110, *I*)
*z* (120, *i*-2̀)

*d* (101, − 1-ī)
*x* (201, − 2-ī)
*e* (301, − 3-ī)

*δ* (1̄01, 1-ī)
*ξ* (2̄01, 2-ī)
*ϵ* (3̄01, 3-ī)

Also, doubtful, *h* (160), *o* (103), *s* (319), *ρ* (236).

$kk''' = 44° \; 6\frac{1}{2}'$
$nn''' = 56° \; 45'$
$ff''' = 78° \; 2'$

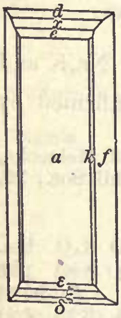
$af = {}^*39° \; 1'$
$mm''' = 116° \; 39'$
$zz' = 34° \; 18'$

$ad = 47° \; 38'$
$ax = {}^*29° \; 27\frac{1}{2}'$
$ae = 20° \; 49\frac{1}{2}'$

$a'\delta = 51° \; 10\frac{1}{2}'$
$a'\xi = {}^*31° \; 1'$
$a'\epsilon = 21° \; 38'$

Des Cloizeaux pointed out a similarity in form between mosandrite and zoisite, and Brögger shows that johnstrupite, mosandrite, and rinkite, very near to each other in composition, are all similar in angle to both zoisite and epidote. He thus compares the prismatic zone of johnstrupite with the orthodomes of epidote and vice versa (cf. also p. 517):

| | | |
|---|---|---|
| Johnstrupite | $100 \wedge 210 = 39° \; 1'$ | $100 \wedge 101 = 48° \; 15'$<br>$100 \wedge \bar{1}01 = 51° \; 53'$ |
| Zoisite | $010 \wedge 120 = 38° \; 58'$ | $010 \wedge 021 = 55° \; 14'$ |
| Epidote | $100 \wedge 10\bar{2} = 42° \; 5'$<br>$100 \wedge 30\bar{2} = 35° \; 7'$ | $100 \wedge 110 = 55° \; 0'$ |



Twins: with tw. pl. *a*. In crystals prismatic ‖ $\acute{c}$ and flattened ‖ *a* (100); the prism *f* (210) most prominent. Faces in prismatic zone vertically striated.

Cleavage: *a* distinct. G. = 3·29. Luster on *a* vitreous, on fracture surfaces resinous to greasy. Color brownish green. Streak yellowish green.

Pleochroism very weak: 𝔠 bright greenish yellow, 𝔟 brownish yellow, 𝔞 bright yellow. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically +. Ax. pl. ‖ *b*. $Bx_o \wedge \acute{c} = \pm 2\frac{1}{4}°$. $Bx_a$ nearly ⊥ *a* (100). Dispersion $\rho > v$, strongly marked; inclined, hardly distinct (0° 13′ for red and green). Axial angles, Bgr.:

Barkevik $2H_{a.r} = 79° \; 5\frac{1}{2}'$ $2H_{o.r} = 125° \; 40'$ $\therefore 2V_r = 71° \; 10\frac{1}{2}'$
$2H_{a.y} = 77° \; 42'$ $2H_{o.y} = 127° \; 40'$ $\therefore 2V_y = 69° \; 54'$ $2E_y = 124° \; 40'$ $\beta = 1{\cdot}546$
$2H_{a.gr} = 75° \; 59\frac{1}{2}'$ $2H_{o.gr} = 131° \; 11'$ $\therefore 2V_{gr} = 68° \; 20'$.

**Comp.**—A complex silicate of the cerium metals, calcium and sodium chiefly with titanium and fluorine.

Brögger calculates the following molecular ratio:

| $\overset{I}{R}_2O$ | CaO | MgO | $\overset{III}{R}_2O_3$ | $\overset{IV}{R}O_2$ | $SiO_2$ | F | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 2·61 | 11·87 | 0·98 | 1·45 | 3·00 | 12 | 7·48 | 1·87 |

And the formula is written, analogous to the epidotes, $\left[\begin{matrix} F_6\overset{IV}{R}_3 \\ F\overset{III}{R} \end{matrix}\right](\overset{I}{R}_2)_4\overset{II}{R}_{13}\overset{III}{R}_2(SiO_4)_{12}$.

Here $\overset{I}{R}_2 = 3Na_2, 1H_2$; $\overset{II}{R} = 12Ca, 1Mg$; $\overset{III}{R}_2 = 1(Ce + Y), 1(Al + Fe)$; $\overset{III}{R} = Ce$; $\overset{IV}{R} = \frac{3}{4}Ti, \frac{1}{4}Zr$, also Th and Ce. Further the group in brackets is regarded as corresponding to the bivalent group $(\overset{III}{R}OH)$ in epidote.

**Anal.**—Bäckström, quoted by Brögger.

| | $SiO_2$ | $TiO_2$ | $ZrO_2$ | $ThO_2$ | $CeO_2$ | $Ce_2O_3$ | $Y_2O_3$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | MgO | $Na_2O$ | $K_2O$ | $H_2O$ | F |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| G. = 3·29 | 30·50 | 7·57 | 2·84 | 0·79 | 0·80 | 12·71[a] | 1·11 | 1·52 | 0·50 | 27·76 | 1·63 | 6·67 | 0·12 | 1·41 | 5·98 = 101·91 |

[a] Incl. $La_2O_3, Di_2O_3$.

**Obs.**—Only known from one of the ledges near Barkevik in the Langesund fiord, Norway; it is associated with wöhlerite, rosenbuschite, eucolite, ægirite, fluorite, elæolite, sodalite, etc.

Named after Prof. Fr. Johnstrup of Copenhagen.

**Ref.**—Dx., Min., 1, 531, 1862, Weibye, Jb. Min., 774, 1849, Bgr., Zs. Kr., **16**, 74, 1890. Crystals earlier described (Bgr., Zs. Kr., **2**, 275, 1878) as mosandrite proved to be låvenite (p. 375).

## 516. MOSANDRITE. *Erdmann*, Berz. JB., **21**, 178, 1841.

Crystals long prismatic ‖ *c* and flattened ‖ *a*, but without terminations so far as observed; vertical faces strongly striated. Forms noted in the prismatic zone, the same as in johnstrupite, and angles nearly the same.

**Forms**: *a* (100, $i\text{-}\bar{i}$), *b* (010, $i\text{-}\grave{i}$), *t* (710, $i\text{-}\bar{7}$), *k* (410, $i\text{-}\bar{4}$), *n* (310, $i\text{-}\bar{3}$), *l* (520, $i\text{-}\bar{\frac{5}{2}}$), *f* (210, $i\text{-}\bar{2}$), *m* (110, *I*), *z* (120, $i\text{-}\grave{2}$), *h* (160, $i\text{-}\grave{6}$).

Sections ‖ *b* show tw. lamellæ ‖ *a*.

Cleavage: *a* rather perfect. H. = 4. G. = 2·93–3·03. Luster of cleavage-face between vitreous and greasy, of other surfaces resinous. Color reddish brown, but altering to dull greenish or yellowish brown. Streak-powder pale yellow or grayish brown. Thin splinters translucent, bright red by transmitted light. Optical characters as with johnstrupite.

**Comp.**—Very near johnstrupite, p. 720.

Brögger calculates the molecular ratio as follows:

| $\overset{I}{R}_2O$ | $\overset{II}{R}O$ | $\overset{III}{R}_2O_3$ | $\overset{IV}{R}O_2$ | $SiO_2$ | F | $H_2O$ |
|---|---|---|---|---|---|---|
| 1·04 | 10·18 | 1·20 | 4·19 | 12 | 2·57 | 10·25 |

The formula is written, also analogous to the epidotes, $\left[\left.\begin{matrix} F_2 \\ (OH)_6 \end{matrix}\right\}\overset{IV}{R}_4\right](\overset{I}{R}_2)_7\overset{II}{R}_{10}\overset{III}{R}_2(SiO_4)_{12}$.

Here $\overset{I}{R}_2 = 6H_2, 1Na_2(K_2)$; $\overset{II}{R} = 10Ca$ (a little Mg,Mn), $\overset{III}{R} = \frac{2}{3}Ce, \frac{1}{3}Y$ and a little Fe; $\overset{IV}{R} = \frac{2}{5}Ti, \frac{2}{5}Zr, \frac{1}{5}Ce$ and a little Th.

**Anal.**—1, Berlin, Pogg., **88**, 156, 1853. 2, Bäckström, quoted by Brögger, Zs. Kr., **16**, 80, 1890.

| | $SiO_2$ | $TiO_2$ | $ZrO_2$ | $ThO_2$ | $CeO_2$ | $Ce_2O_3$ | $Y_2O_3$ | $Fe_2O_3$ | MnO | CaO | MgO | $Na_2$ | $K_2O$ | $H_2O$ | F |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 29·93 | 9·90 | — | — | — | 26·56[b] | — | 1·83 | — | 19·07 | 0·75 | 2·87 | 0·52 | 8·90 | — = 100·33 |
| 2. | [30·71[a]] | 5·33 | 7·43 | 0·34 | 6·34 | 10·45[b] | 3·52 | 0·56 | 0·45 | 22·53 | 0·63 | 2·44 | 0·38 | 7·70 | 2·06 = 100·87 |

[a] A direct determination gave 29·61.

[b] Incl. $(La,Di)_2O_3$.

**Pyr., etc.**—In the closed tube gives water. B.B. fuses with intumescence at 3 to a brown glass. With salt of phosphorus in R.F. gives a violet bead (titanium), and with borax in O.F. gives an amethystine bead (manganese). Decomposed by hydrochloric acid, with separation of silica and formation of a dark red solution, which, on heating, gives off chlorine and becomes yellow.

**Obs.**—Occurs on the small island Låven in the Langesund fiord, also on the neighboring island Stokö, and on the reefs near Barkevik; it is associated with leucophanite, eucolite, elæolite, ægirite, black mica. Readily undergoes alteration.

Named after the Swedish chemist G. G. Mosander (1797–1858).

### 517. RINKITE. *Lorenzen*, Medd. Grönl., **7**, 1884, and Zs. Kr., **9**, 248, 1884.

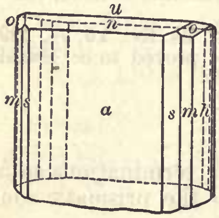
Monoclinic. Axes: $\grave{a} : \bar{b} : \grave{c} = 1{\cdot}5688 : 1 : 0{\cdot}2922$; $\beta = 88^\circ\ 47\frac{1}{4}' = 001 \wedge 100$ Lorenzen.

$100 \wedge 110 = 57^\circ\ 28\frac{3}{4}'$, $001 \wedge 101 = 10^\circ\ 30\frac{1}{2}'$, $001 \wedge 011 = 16^\circ\ 17'$.

**Forms:** *a* (100, *i*-$\bar{\imath}$), *s* (320, *i*-$\frac{3}{2}$), *m* (110, *I*), *h* (120, *i*-2̀); *n* (101, − 1-$\bar{\imath}$), *u* ($\bar{1}$01, 1-$\bar{\imath}$); *o* (341, − 4-$\frac{4}{3}$).

The domes 101, $\bar{1}$01 correspond to 105, $\bar{1}$05 of johnstrupite.

Angles: *ss‴* = 92° 33′, *mm‴* = 114° $57\frac{1}{2}'$, *am* = *57° $28\frac{3}{4}'$, *hh′* = 35° 22′, *an* = *78° $16\frac{3}{4}'$, *a′u* = 80° 37′, *nu* = *21° $5\frac{5}{6}'$.



Crystals flattened ∥ *a*; with a zonal structure parallel the faces, and with twinning lamellæ ∥ *a*.

Cleavage: *a* distinct. H. = 5. G. = 3·46. Luster vitreous to greasy. Color yellowish brown to straw-yellow. Pleochroic. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically +. Ax. pl. ⊥ *b* and inclined $7\frac{1}{2}$ to $\grave{c}$. $Bx_a$ nearly normal to *a*. Dispersion horizontal distinct, also $\rho > v$.

**Comp.**—Near johnstrupite and mosandrite.

Brögger suggests $[F_8Ti_4]Na_9Ca_{11}Ce_3(SiO_4)_{12}$.

**Anal.**—Lorenzen, mean of five partial analyses:

| $SiO_2$ | $TiO_2$ | $Ce_2(La,Di)_2O_3$ | $Y_2O_3$ | FeO | CaO | $Na_2O$ | F | |
|---|---|---|---|---|---|---|---|---|
| 29·08 | 13·36 | 21·25 | 0·92 | 0·44 | 23·26 | 8·98 | 5·82 | = 103·11, less O 2·45 = 100·66 |

**Pyr., etc.**—Fuses B.B. rather easily to a black shining glass with continued intumescence. Dissolves in the borax bead, giving a yellow color in the O.F.; with salt of phosphorus, in R.F. violet (titanium), in O.F. colorless but with more of the mineral becomes enamel-like.

Easily decomposed by dilute acids with separation of silica carrying titanium.

**Obs.**—Occurs in sodalite-syenite at Kangerdluarsuk, Greenland, with arfvedsonite, ægirite, eudialyte, lithia mica, steenstrupine.

Named after Dr. Rink, at one time director of the Danish-Greenland commerce.

---

### 518. PEROVSKITE. Perowskit *G. Rose*, Pogg., **48**, 558, 1839, Reis. Ural, **2**, 128, 1842. Perofskite.

Isometric or pseudo-isometric. Observed forms[1]:

*a* (100, *i*-*i*)
*d* (110, *i*)
*o* (111, 1)
*k* (520, *i*-$\frac{5}{2}$)
*e* (210, *i*-2)
*g* (320, *i*-$\frac{3}{2}$)
*Δ* (11·8·0, *i*-$\frac{11}{8}$)
*ϑ* (430, *i*-$\frac{4}{3}$)
*λ* (540, *i*-$\frac{5}{4}$)
*p* (221, 2)
*m* (311, 3-3)
*n* (211, 2-2)?
*ρ* (944, $\frac{9}{4}$-$\frac{9}{4}$)
*β* (322, $\frac{3}{2}$-$\frac{3}{2}$)
*z* (942, $\frac{9}{4}$-$\frac{9}{2}$)[2]
*Θ* (10·4·3, $\frac{10}{3}$-$\frac{5}{2}$)
*Γ* (832, 4-$\frac{8}{3}$)
*F* (643, 2-$\frac{3}{2}$)
*x* (432, 2-$\frac{4}{3}$)[2]

Crystals in general (Ural, Zermatt) cubic in habit and often highly modified, but the planes often irregularly distributed. Cubic faces striated parallel to the edges and apparently penetration-twins, as if of pyritohedral individuals. Again (Tyrol) the cubic faces less developed and the forms *m* (311), *ρ* (944) prominent. Also (Zermatt) in reniform masses showing small cubes.

Cleavage: cubic, rather perfect. Fracture uneven to subconchoidal. Brittle. H. = 5·5. G. = 4·017 Achmatovsk, Rose, 4·03–4·039 Zermatt, Dmr. Luster adamantine to metallic-adamantine. Color pale yellow, honey-yellow, orange-yellow, reddish brown, grayish black. Streak colorless, grayish. Transparent to opaque. Usually exhibits anomalous double refraction.

Geometrically considered, perovskite conforms to the isometric system; optically, however, it is uniformly biaxial and usually positive. The molecular structure (also as developed by etching, Baumhauer) seems to correspond to orthorhombic symmetry. (See the authors referred to under [2].) Sections (‖ *a*) of cubic crystals from the Ural and Zermatt show tw. lamellæ parallel to both sets of cubic edges, with diagonal extinction; the bisectrix is normal to a dodecahedral face, the axial angle variable (up to 90°), the character +, also −. Similar sections from the Tyrolese crystals, in which the forms *m* (311) and *ρ* (944) often predominate, show fine tw. lamellæ parallel the diagonals, while the bisectrix is ⊥ *a*, the optical character +, the axial angle small, sometimes sensibly 0°.

In general the form and optical character are partially explained by the assumption of an orthorhombic form, with a prismatic angle of 90° (corresponding to the two pair of cubic faces), and twinned with *p* (111) as tw. pl., and also *m* (110) in some cases. It seems more probable, however, as urged by Klein, especially as the structure differs in specimens from different localities, that the form was originally isometric and that the optical anomalies are due to secondary causes, but the subject still requires much elucidation. The transformation of the molecular structure to the isotropic condition by increase of temperature has not been accomplished, although this is readily done with boracite, to which perovskite is closely related in structure and optical characters.

**Comp.**—Calcium titanate, $CaTiO_3$ = Titanium dioxide 58·9, lime 41·1 = 100. Iron is present in small amount replacing the calcium.

**Anal.**—1, Brooks, Pogg., **62**, 596, 1841. 2, Jacobson, ibid. 3, Brun, Zs. Kr., **7**, 389, 1882. 4, Damour, Ann. Mines, **6**, 512, 1854. 5, Mauro, quoted by Strüver, Trans. Acc. Linc., **4**, 210, 1880. 6, Sauer, Zs. G. Ges., **37**, 445, 1885. Also an approximate analysis, showing a large amount of iron, by Kastle, Am. J. Sc., **34**, 141, 1887; further by Eakins, ib., **37**, 219, 1889.

| | G. | $TiO_2$ | CaO | FeO | | |
|---|---|---|---|---|---|---|
| 1. Achmatovsk, *brown* | | 59·00 | 36·76 | 4·79 | MgO,MnO 0·11 | = 100·07 |
| 2. “ *black* | | 58·96 | 39·20 | 2·06 | MgO,MnO *tr.* | = 100·22 |
| 3. Zermatt, *yellow* | 3·974 | 59·39 | 39·80 | 0·91 | | = 100·10 |
| 4. “ | | 59·23 | 39·92 | 1·14 | | = 100·29 |
| 5. Val Malenco | 3·95 | 58·66 | 41·47 | — | | = 100·13 |
| 6. Oberwiesenthal | | 58·66 | 38·35 | 2·07 | | = 99·08 |

**Pyr., etc.**—In the forceps and on charcoal infusible. With salt of phosphorus in O.F. dissolves easily, giving a greenish bead while hot, which becomes colorless on cooling; in R.F. the bead changes to grayish green, and on cooling assumes a violet-blue color. Entirely decomposed by boiling sulphuric acid.

**Obs.**—Occurs in small crystals or druses of crystals, all of dark colors, associated with crystallized chlorite, and magnetic iron in chlorite slate, at Achmatovsk, near Zlatoust, in the Ural; at Schelingen in the Kaiserstuhl, in white or yellowish granular limestone, with mica, magnetite, and pyrochlore or koppite (questioned by Knop, Zs. Kr., 1, 284, 1877); in the valley of Zermatt, near the Findelen glacier, where crystalline masses occur, in talcose schist, as large as the fist, and the interior, if not the whole, is of a light yellow color, along with garnet, vesuvianite, titanite, zircon, corundum, rutile, titanic iron, serpentine, etc.; at Wildkreuzjoch, between Pfitsch and Pfunders in Tyrol, but rare (cf. Hbg., l. c., and Rath, Pogg., **144**, 595, 1871). At Mte. Lagazallo, Val Malenco, Sondrio, northern Italy, with magnetite and amianthus. Rare on the island Låven in the Langesund fiord, associated with leucophanite. Bgr., Zs. Kr., **16**, 508, 1890.

Sometimes noted in microscopic octahedral crystals as a rock constituent; thus in nephelite- and melilite-basalts; as of Wartenberg in Bohemia; Hochbohl near Owen in Würtemberg; the Saxon Erzgebirge, basaltic lava of Scharteberg in the Eifel (doubly refracting, Hussak), etc.; also in serpentine (altered peridotyte) at Syracuse, N. Y. (cf. Williams, Am. J. Sc., **34**, 137, 1887); in peridotyte of Elliott Co., Ky. (Diller, ib., **37**, 219, 1889). Also noted as a result of the alteration of titanite (Schneider, Jb. Min., **1**, 99, 1889).

Named after von Perovski of St. Petersburg.

**Artif.**—Formed in crystals by making lime act at a high temperature on titanium silicate (Ebelmen); also by Hautefeuille (cf. Fouqué-Lévy, Synth. Min., 176, 1882). The artificial crystals show the optical characters of the natural mineral.

**Ref.**—[1] See Rose, l. c., also Dx., Ann. Ch. Phys., **13**, 338, 1845; Kk., Min. Russl., **1**, 199, 1853, **6**, 388, 1874, **7**, 375, 1878, **8**, 39, 1881; Mlr., Min., 461, 1852; Hbg., Wildkreuzjoch, Min. Not., **4**, 20, 1861, **10**, 38, 1871, **11**, 1, 1873.

[2] On the optical characters, see Dx., l. c. and Opt. Propr., **2**, 81, 1858; N. R., 84, 1867; Zs. G. Ges., **26**, 932, 1874; Jb. Min., 160, 1877, **43**, 372, 1878. Also Ben Saude, Preisschrift, Göttingen, 1882; Mallard, Bull. Soc. Min., **5**, 233, 1882; Klein, Jb. Min., **1**, 245, 1884, and 175 ref. (the latter a notice of Ben Saude). On the results of etching, see Baumhauer, Zs. Kr., **4**, 187, 1879.

**519. DYSANALYTE.** *A. Knop*, Zs. Kr., **1**, 284, 1877. Perovskite of former writers.

Isometric; in cubes.

Cleavage: cubic. H. = 5–6. G. = 4·13. Luster submetallic. Color iron-black. Opaque.

**Comp.**—A titano-niobate of calcium and iron approximating (anal. 3) to $6RTiO_3.RNb_2O_6$.

Mar calculates for anal. 4 the molecular ratio, $TiO_2 : (Nb,Ta)_2O_5 : Y_2O_3,Fe_2O_3 : CaO = 0·54 : 0·027 : 0·05 : 0·60$.

**Anal.**—1, 2, Seneca, Lieb. Ann., **104**, 371, 1857. 3*a*, Knop, l. c.; 3*b*, same, deducting $SiO_2$. 4, F. W. Mar, Am. J. Sc., **40**, 403, 1890.

| | G. | $TiO_2$ | $Nb_2O_5$ | $Ta_2O_5$ | $Y_2O_3$[a] | FeO | $Ce_2O_3$[b] | CaO | $Na_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Kaiserstuhl | 4·02 | 58·95 | — | — | — | 6·23 | — | 35·69 | — | = 100·87 |
| 2. " | | 59·30 | — | — | — | 5·99 | — | 35·94 | — | = 101·23 |
| 3*a*. " | | 40·57 | 22·73 | — | — | 6·12[c] | 5·58 | 19·36 | 3·50 | $SiO_2$ 2·31, MgO, [$K_2O,Al_2O_3$,F *tr*. = 100·17 |

[a] Yttrum earths. [b] Cerium oxides. [c] Incl. 0·42 MnO. [d] 0·43 MnO. [e] $Fe_2O_3$.

**Obs.**—Found in the granular limestone of Vogtsburg, Kaiserstuhlgebirge, Baden. The mineral has previously been called perovskite, but is in fact intermediate between the titanate, perovskite, and the niobates, pyrochlore and koppite. Named, in allusion to the difficulty of the analysis, from *δυσανάλυτος*, *hard to undo.*

A related mineral, which has also long passed as perovskite, occurs with magnetite, brookite, rutile, etc., at Magnet Cove, Arkansas. It is in octahedrons or cubo-octahedrons, black or brownish black in color and submetallic in luster. The amount of niobium (and tantalum) present is much smaller than in the mineral from the Kaiserstuhl and it hence is more closely allied to perovskite. Ben Saude has shown that sections ‖ *a* (100) and *o* (111) show twinning lamellæ analogous to perovskite.

HYDROTITANITE *Koenig*, Proc. Acad. Philad., 82, 1876. An altered form of the so-called perovskite (dysanalyte) from Magnet Cove, Arkansas. G. = 3·681. Soft. Color yellowish gray. An analysis afforded:

$TiO_2$ 82·82 $Fe_2O_3$ 7·76 MgO 2·72 CaO 0·80 $H_2O$ 5·50 V *tr*. = 99·60.

This does not correspond to any definite formula.

# Oxygen Salts.

## 3. NIOBATES, TANTALATES.

The Niobates and Tantalates are chiefly salts of metaniobic and metatantalic acid, $RNb_2O_6$ and $RTa_2O_6$; also in part Pyroniobates, $R_2Nb_2O_7$, etc. Titanium is prominent in a number of the species, which are hence intermediate between the niobates and titanates. Niobium and tantalum also enter into the composition of a few silicates, as wöhlerite, p. 376, låvenite, p. 375, etc.

### 1. Pyrochlore Group. Isometric.

| | | |
|---|---|---|
| 520. | **Pyrochlore** | $RNb_2O_6.R(Ti,Th)O_3.NaF$ |

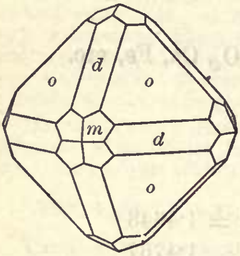
### 1. Pyrochlore Group. Isometric.

**520. PYROCHLORE.** Pyrochlor (fr. Fredriksvärn) *Wöhler*, Pogg., **7**, 417, 1826. Hydrochlor, Fluochlor, *Herm.*, J. pr. Ch., **50**, 186, 187, 1850.



Miask, Kk.

Isometric. Observed forms:

*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1); *m* (311, 3-3), *n* (211, 2-2)?

Commonly in octahedrons; also in irregular embedded grains.

Cleavage: octahedral, sometimes distinct. Fracture conchoidal. Brittle. H. = 5–5·5. G. = 4·2–4·36; 4·32, Miask, Rose; 4·203, ib., Hermann; 4·359, ib., Rg.; 4·203–4·221, Fredriksvärn, Hayes; 4·228, ib., Rg. Luster vitreous or resinous, the latter on fracture surfaces. Color brown, dark reddish or blackish brown. Streak light brown, yellowish brown. Subtranslucent to opaque.

**Comp.**—Chiefly a niobate of the cerium metals, calcium and other bases, with also titanium, thorium, fluorine. Probably essentially a metaniobate with a titanate, $RNb_2O_6.R(Ti,Th)O_3$; the part played by the fluorine in this and the following species is doubtful.

Rammelsberg (Min. Ch., Erg., 191, 1886) calculates for the pyrochlore from Miask $[5RNb_2O_6.4R(Ti,Th)O_3] + 4NaF$; for that from "Brevik" $[5RNb_2O_6.2R(Ti,Th)O_3] + 4NaF$; Fredriksvärn $[R_2Nb_2O_7.RTiO_3] + NaF$. Brögger (Zs. Kr., **16**, 511, 1890) suggests that the metaniobate may represent the original composition, the pyroniobate be a result of alteration.

**Anal.**—1–3, Rg., Ber. Ak. Berlin, 183, 1871. Also earlier anals., 5th Ed., p. 513.

| | G. | $Nb_2O_6$ | $TiO_2$ | $ThO_2$ | $Ce_2O_3$ | CaO | FeO | UO | MgO | $Na_2O$ | F |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. Miask | 4·359 | $\frac{8}{3}$ 53·19 | 10·47 | 7·56 | 7·00 | 14·21 | 1·84 | — | 0·22 | 5·01 | — |
| 2. "Brevik" | 4·220 | 58·27 | 5·38 | 4·96 | 5·50 | 10·93 | 5·53 | | — | 5·31 | 3·75<br>[ign. 1·53 = 101·16 |
| 3. Fredriksvärn | 4·228 | 47·13 | 13·52 | — | 7·30 | 15·94 | 10·03 | — | 0·19 | 3·12 | 2·90<br>[ign. 1·39 = 101·52 |

**Pyr., etc.**—Pyrochlore from Miask gives but traces of water in the closed tube. B.B. infusible, but turns yellow and colors the flame reddish yellow. When ignited it glows momentarily as if taking fire, the same phenomenon as observed with gadolinite. With borax and salt of phosphorus in both flames gives a light green bead, becoming colorless on cooling. A saturated bead of borax gives a greenish gray enamel in R.F., while that with salt of phosphorus is reddish gray. Decomposed by concentrated sulphuric acid with evolution of fluorine (G. Rose). Pyrochlore from Norway gives water in the closed tube, and B.B. fuses with difficulty to a dark brown slaggy mass. With borax in R.F. gives a dark red bead, which by flaming turns to a grayish blue to pure blue enamel. Dissolves with effervescence in salt of phosphorus, giving in O.F. a yellow bead while hot, becoming grass-green on cooling (uranium). In R.F. the bead is made dark red to violet (titanium). Fused with soda gives a green color (manganese). All varieties are decomposed by fusion with potassium bisulphate. Most specimens are sufficiently decomposed by hydrochloric acid to give a blue color when the concentrated solution is boiled with metallic tin; this color disappears after a time, and almost immediately if diluted with water.

**Obs.**—Occurs embedded in elæolite-syenite at Fredriksvärn and Laurvik, Norway, with zircon, polymignite, amphibole, and xenotime; on the island Lövö, opposite Brevik; on Stokö, Lille Arö, and other points in the Langesund fiord (Bgr., Zs. Kr., **16**, 509, 1890); near Miask in the Ural.

Lacroix mentions an octahedral mineral resembling the Norwegian pyrochlore as occurring with astrophyllite and zircon, in the syenite of St. Peter's Dome, Pike's Peak, Colorado (C. R., **109**, 39, 1889).

Named from *πῦρ*, *fire*, and *χλωρός*, *green*, because B.B. it becomes yellowish green.

**520A. Koppite.** *Knop*, Jb. Min., 67, 1875.

Isometric; in minute embedded dodecahedrons, G. = 4·45–4·56. Color brown. Transparent.

**Comp.**—Essentially a pyroniobate of cerium, calcium, etc.; formula as given by Rammelsberg (Min. Ch., Erg., 191), $5R_2Nb_2O_7.2NaF$.

**Anal.**—1, Knop, l. c. and Zs. G. Ges., **23**, 656, 1871. 2, G. H. Bailey, J. Ch. Soc., **49**, 153, 1886. An earlier analysis by Bromeis is quoted by Knop.

| | $Nb_2O_5$ | $TiO_2$ | $ZrO_2$ | $(Ce,La,Di)_2O_3$ | FeO | CaO | MgO | $Na_2O$ | $K_2O$ | F |

[a] MnO 0·40.

**Obs.**—Occurs with apatite in a granular limestone near Schelingen, Kaiserstuhlgebirge, Baden.

Named after Prof. Hermann Kopp of Heidelberg.

**521. HATCHETTOLITE.** *J. L. Smith*, Am. J. Sc., **13**, 365, 1877. *O. D. Allen.* ibid., **14**, 128, 1877.

Isometric. In octahedrons with also the subordinate forms *a* (100, *i-i*) and *m* (311, 3-3).

Fracture subconchoidal. Brittle. H. = 5. G. = 4·77–4·90. Luster resinous. Color yellowish brown. Translucent.

**Comp.**—A tantalo-niobate of uranium, near pyrochlore, approximating to $R(Nb,Ta)_2O_6 + H_2O$ with $R = UO_2 : Ca = 1·3$ and $Nb : Ta = 2 : 1$. The water present may be due to alteration.

**Anal.**—1, 2, 3, Smith, l. c. 4, 5, Allen, l. c.

</table>

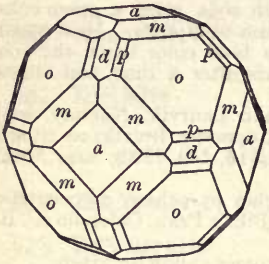
[a] With cerium oxide.

From analysis 4, Allen deduces the formula $R_2(Nb,Ta)_2O_7 + 2R(Nb,Ta)_2O_6 + 4H_2O$, with $R = UO_2,Ca,Fe,Mg,Na_2$. Allen calls attention to the close relation to pyrochlore, and suggests that the original mineral in this case may have been anhydrous and hence analogous to it in composition. It is united with pyrochlore by some authors, which species, however, contains little or no uranium.

**Pyr.**—Nearly the same as for pyrochlore.

**Obs.**—Occurs associated with samarskite, sometimes implanted upon it in parellel position, in the mica mines of Mitchell Co., North Carolina. Named after the English chemist, Charles Hatchett (1765–1847).

**522. MICROLITE.** Microlite *C. U. Shepard*, Am. J. Sc., **27**, 361, 1835, **32**, 338, 1837 **43**, 116, 1842. Pyrochlore *Hayes*, ib., **43**, 33, 1842, **46**, 158, 1844.



Amelia C. H., Va., after Feist.

Isometric. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *i*), *o* (111, 1), *p* (221, 2), *m* (311, 3-3) *n* (211, 2-2)?

Habit octahedral; crystals often very small. Fracture conchoidal. Brittle. H.=5·5. G.=5·485–5·562, the last from a large crystal, Shepard; 5·405, Hayes; 6·13 Virginia, Hidden. Luster resinous. Color pale yellow to brown, rarely hyacinth-red. Streak pale yellowish or brownish. Transparent to translucent or nearly opaque.

**Comp.**—Essentially a calcium pyro-tantalate, $Ca_2Ta_2O_7$, but containing also niobium, fluorine, and a variety of bases in small amount.

Dunnington calculates $3Ca_2Ta_2O_7 + NbOF_3$. Rammelsberg deduces from the same analysis $[R_2(Ta,Nb)_2O_7.2R(Ta,Nb)_2O_6] + 3NaF$.

**Anal.**—1, Dunnington, Am. Ch. J., 3, 130, 1881. 2, A. Nordenskiöld, G. För. Förh., 3, 282, 1872.

[a] Incl. 0·13 $Al_2O_3$. [b] FeO *tr.* [c] Incl. 0·29 $K_2O$.

**Pyr., etc.**—B.B. infusible. In salt of phosphorus difficultly soluble, giving in O.F. a bead yellow while hot, and colorless on cooling. In R.F. after long blowing yields a pale bluish green bead. Not attacked by hydrochloric acid, but decomposed on fusion with potassium bisulphate and the solution of the fused mass remains uncolored when boiled with metallic tin. Slowly decomposed by sulphuric acid.

**Obs.**—First found at Chesterfield, Mass., in minute octahedrons in an albite vein, with red and green tourmaline, spodumene, columbite, and a little cassiterite; similarly associated at Branchville, Conn., and at Utö, Sweden. Also in fine crystals up to 1 in. in diameter, and in imperfect crystals (up to 4 lbs.) at the mica mines at Amelia Court House, Amelia Co., Va., with monazite, columbite, spessartite, beryl, fluorite, etc. (cf. Fontaine, Am. J. Sc., **25**, 335, 1883); the crystals, embedded in smoky quartz, are rarely clear, highly polished, and resembling pyrope in color (Hidden, ib., **30**, 82, 1885). Also in the granitic veins of Elba (Corsi, Boll. Com. G., 564, 1881). Cf. pyrrhite, below.

Named from *μικρός*, *small*, alluding to the minute size of the crystals at the original locality.

**Ref.**—[1] See Feist, Zs. Kr., **11**, 255, 1885.

A mineral related to microlite, from Haddam, Conn., is called *haddamite* by C. U. Shepard (Am. J. Sc., **50**, 93, 1870; Min. Contr., 1877). What its true character is, if it be a distinct species, has not been determined.

PYRRHITE *G. Rose*, Pogg., **48**, 562, 1840, Reis. Ural., **2**, 1842.

Isometric; in octahedrons. Cleavage not observed. H. = 6. Luster vitreous. Color orange-yellow. Subtranslucent. In composition probably a niobate, related to pyrochlore, and perhaps identical with microlite.

B.B. infusible, but blackens, and colors the flame deep yellow. In fragments difficultly soluble in salt of phosphorus, but in fine powder it is readily taken up by this salt, as well as by borax, forming a clear glass when cold if only a small portion is used, while if saturated it is yellowish green, becoming somewhat more intense in R.F. Fused with soda on charcoal, it spreads out and is absorbed by the coal, giving a slight white coating, somewhat resembling oxide of zinc; it yields no metallic spangles when the surface of the coal is removed and rubbed in the mortar. Insoluble in hydrochloric acid (G. Rose).

Pyrrhite was found by von Perovski of St. Petersburg at Alabashka, near Mursinka in the Ural, where it occurs in drusy feldspar cavities, containing also lepidolite, albite, and topaz. The largest crystal was but three lines long. Crystals from San Piero, Elba, referred here by Rath (Zs. G. Ges., **22**, 672, 1870) are regarded by Corsi as microlite, which may also be true of the Uralian mineral (ref. above). Cf. also Schrauf, Ber. Ak. Wien, **63** (1), 187, 1871.

Named from *πυῤῥός*, *yellowish red* or *fire-like*.

To Rose's pyrrhite J. E. Teschemacher refers small orange-red, isometric octahedrons, found with albite on San Miguel, one of the Azores (J. Nat. H. Bost., **4**, 499, 1844; Proc. id., **2**, 108, 1846), along with tetragonal octahedrons of *azorite* (p. 484). The crystals are a half to two lines long, and those of minute size are transparent. They are called *azor-pyrrhite* by Hubbard, who mentions a similar mineral (G. = 4·1–4·3) in the sanidine-bombs of the Laacher See (Ber. nied. Ges., June 7, 1886) associated with titanite and noselite. Cf. also Osann (Jb. Min., **1**, 115, 1887, **1**, 117, 1888), who has further investigated the mineral from the Azores and finds the hardness below 6 and by chemical tests identifies Nb(Ti?)Ti, Fe, Na, Ca. It is hence, as urged by him, probably near pyrochlore, and may be identical with it; the specific gravity seems to be less than that of the pyrrhite from the Ural and Elba.

The chemical and blowpipe trials of A. A. Hayes (Am. J. Sc., **9**, 423, 1850, detailed in 5th Ed., p. 763) on specimens by Teschermacher made the crystals consist of niobate of zirconium, colored apparently by oxides of iron, uranium, and manganese, but the results are not conclusive.

## 2. Fergusonite Group. Tetragonal.

**523. FERGUSONITE.** *Haidinger*, Ed. Phil. Trans., **10**, 274, 1826. Tyrite *Forbes*, Ed. N. Phil. J., **1**, 67, 1855; Phil. Mag., **13**, 91, 1857. Bragite *Forbes* and *Dahll*, Nyt Mag., **8**, 227, 1855. Yttrotantalite pt. (yellow).

Tetragonal; with pyramidal hemihedrism. Axis $\dot{c} = 1·4643$; $001 \wedge 101 = 55° \, 40\frac{1}{6}'$ Miller[1].

**Forms**[2]: *c* (001, *O*); *g* (320, $i\text{-}\frac{3}{2}$); *s* (111, 1); *z* (321, $3\text{-}\frac{3}{2}$).

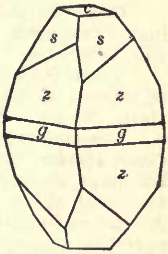
Angles: $cs = 64° \, 13\frac{1}{2}'$, $ss' = {}^*79° \, 6'$, $cz = 79° \, 16\frac{1}{2}'$, $zz''' = 88° \, 1'$.

The form is near that of the scheelite group, p. 985.

Crystals pyramidal or prismatic in habit, sometimes with basal plane prominent and often showing the hemihedral form, the pyramid of the third series, *z* (321).

Cleavage: *s* (111) in traces. Fracture subconchoidal. Brittle. H. = 5·5–6. G. = 5·838 Allan; 5·800 Turner; diminishing to 4·3 when largely hydrated. Luster externally dull, on the fracture brilliantly vitreous and submetallic. Color brownish black; in thin scales pale liver-brown. Streak pale brown. Subtranslucent to opaque.

**Comp.**—Essentially a metaniobate (and tantalate) of yttrium with erbium, cerium, uranium, etc., in varying amounts; also iron, calcium, etc. General formula $\overset{\text{III}}{R}(Nb,Ta)O_4$ with $\overset{\text{III}}{R} = Y,Er,Ce$.



Haidinger.

Water is usually present and sometimes in considerable amount, but probably not an original constituent; the specific gravity falls as the amount increases, cf. anals. 12, 13, and Hidden & Mackintosh, l. c.

**Anal.**—1–9, Rg., Ber. Ak. Berlin, 406, 1871, and Min. Ch., 362, 1875; 2–5, of the so-called yellow (or brown) yttrotantalite. 10, W. H. Seamon, Ch. News, **46**, 204, 1882. 11, J. L. Smith, Am. J. Sc., **13**, 367, 1877. 12, 13, Hidden & Mackintosh, Am. J. Sc., **38**, 482, 1889. Earlier anals., 5th Ed., p. 525.

On the absorption spectra of the rare earths in fergusonite, see Krüss and Nilson, Öfv. Ak. Stockh., **44**, 373, 1887; on metallic acids, ib., p. 267.

**Pyr., etc.**—Fergusonite from Greenland gives in the closed tube a little water. B.B. infusible; on charcoal its color becomes pale yellow. With borax dissolves with difficulty, giving a yellow bead while hot, the insoluble portion being white; the saturated bead is yellowish red, and is made opaque by flaming. Slowly dissolved by salt of phosphorus, leaving a white insoluble residue; in O.F. the bead is yellow, while in R.F. it is colorless, or, if saturated, slightly reddish, becoming opaque on cooling; treated with tin the bead remains uncolored, while the insoluble residue is made flesh-red. Decomposed by soda without dissolving, leaving a reddish slag; with soda on charcoal affords globules of metallic tin (Berzelius). When evaporated with sulphuric acid yields a white residue, which, treated with hydrochloric acid and metallic zinc, gives a bluish green color. Tyrite decrepitates and yields much water in the closed tube (Forbes).

**Obs.**—Fergusonite was discovered by Giesecke, near Cape Farewell in Greenland, disseminated in quartz, and named after Robert Ferguson of Raith. Also found at Ytterby, Sweden, and Kårarfvet. In the granite of Königshain, near Görlitz, Silesia (Woitschach).

*Tyrite* is associated with euxenite at Hampemyr on the island of Tromö, and Helle on the mainland; at Näskul, about ten miles east of Arendal. *Bragite* of Forbes and Dahll is from Helle, Narestö, Alve, and Askerö, Norway.

Fergusonite is found in the U. S., at Rockport, Mass., in granite; on the allanite of Amelia Court House, Va. (?, sipylite); in the Brindletown gold district, Burke Co., N. C., in gold-washings, and similarly near Golden P. O., Rutherford Co.; also from near Spruce Pine, Mitchell Co.; with zircon near Storeville, Anderson Co., S. Carolina (Hidden, Am. J. Sc., **41**, 440, 1891). At the gadolinite locality (p. 511) in Llano Co., Texas, it occurs in considerable quantity with cyrtolite, thorogummite, magnetite, etc., in masses sometimes weighing over a pound, also in large rough crystals; the mineral is often hydrated to a greater or less extent, cf. anals. 12, 13.

**Ref.**—[1] Min., 465, 1852. Haidinger gives 79° 32′.

RUTHERFORDITE *C. U. Shepard*, Am. Assoc., **4**, 312, 1850, Am. J. Sc., **12**, 209, 1851. *T. S. Hunt*, ib., **14**, 344, 1852.

In crystals and grains, without cleavage. H. = 5·5. G. = 5·55–5·69. Luster vitreo-resinous. Color blackish brown. Opaque, in thin fragments translucent. Occurs at the gold mines of Rutherford Co., North Carolina, along with rutile, brookite, zircon, and monazite.

Shepard later announced (Am. J. Sc., **20**, 57, 1880) that rutherfordite was probably identical with fergusonite, and of the correctness of this there seems little doubt.

KOCHELITE *M. Websky*, Zs. G. Ges., **20**, 250, 1868.

Tetragonal? In columnar incrustations passing into rounded, apparently square octahedrons, occasionally showing prismatic planes. Color brownish isabella-yellow to honey-yellow. Translucent. Luster dull greasy. H. = 3–3·5. G. = 3·74 (?). An incomplete analysis gave:

| $Nb_2O_5$ | $ZrO_2$ | $ThO_2$ | $SiO_2$ | $Y_2O_3$ | $UO_3$ | $Al_2O_3$ | $Fe_2O_3$ | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 29·49 | 12·81 | 1·23 | 4·49 | 17·22 | 0·43 | 1·41 | 12·48 | 2·10 | 6·52 | PbO?$Na_2O$? loss 11·82 = 100 |

In the closed tube yields water, and the mineral turns reddish. B.B. in the forceps fuses only on the edges to a black glass, coloring the flame yellow. With salt of phosphorus reacts for iron, but in R.F. fuses to a clear bead, showing only a faint reaction for uranium. With soda on charcoal yields a yellowish white enamel, but no metallic globules.

Occurs as an incrustation upon a mixture of titanic iron and crystals of fergusonite in a coarse granite in the Kochelwiese, near Schreiberhau in Silesia.

The composition is near that of fergusonite, but further investigation is needed. The density is remarkably low for a mineral containing so large a percentage of metallic acids.

**524. SIPYLITE.** *J. W. Mallet*, Am. J. Sc., **14**, 397, 1877; **22**, 52, 1881.

Tetragonal. Axis $\dot{c} = 1·4767$; 001 ∧ 101 = 55° 53$\frac{3}{5}$′ Mallet.

Rarely in octahedral crystals; $pp'$ = *79° 15′, $pp''$ = 128° 50′ (127° meas.). Usually imperfectly crystalline, or in irregular masses.

Cleavage: $p$ (111), distinct. Fracture small conchoidal and uneven. Brittle. H. = 6 nearly. G. = 4·89. Luster resinous and pseudo-metallic. Color brownish black to brownish orange; in splinters red-brown. Streak light cinnamon-brown to pale gray. Translucent.

**Comp.**—A niobate of erbium chiefly, also the cerium metals, etc.

**Anal.**—W. G. Brown, l. c.

| $Nb_2O_5$ | $WO_3$ | $SnO_2$ | $ZrO_2$ | $Er_2O_3$ | $Ce_2O_3$ | $La_2O_2$ | $Di_2O_3$ | UO | FeO | BeO | MgO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ |

| 48·66[a] | 0·16 | 0·08 | 2·09 | 27·94[b] | 1·37 | 3·92[c] | 4·06[d] | 3·47 | 2·04 | 0·62 | 0·05 | 2·61 | 0·16 | 0·06 | 3·19 |

[MnO,$Li_2O$,F *tr.* = 100·48

[a] With $Ta_2O_5$ about 2 p. c. [b] With $Y_2O_3$ about 1 p. c. [c] $Di_2O_3$ *tr.* [d] $Ce_2O_3$ *tr.*

Taking together the acid oxides of niobium, tantalum, tungsten, tin, and zirconium as $Nb_2O_5$, and reducing all the basic elements to the form RO, and neglecting the water, the ratio RO : $Nb_2O_5$ = 221 : 100 is obtained, which corresponds to the formula: $R_3Nb_2O_8 + 4R_2Nb_2O_7$. Mallet prefers to include the water, making the hydrogen basic, and deduces on this supposition the formula: $R_3Nb_2O_8$. This view is supported by the fact that in form sipylite is very near fergusonite.

**Pyr.**—B.B. decrepitates, and glows brilliantly, becomes pale greenish yellow and opaque; infusible. In the closed tube gives off acid water. With borax in O.F. gives a yellow bead, pale on cooling; in R.F. assumes a greener tint. Boiled in strong HCl partially dissolves, the solution reacting for zirconium with turmeric paper; when metallic tin is added and the solution diluted, a sapphire-blue color is obtained (niobium). Decomposed completely, though slowly, in boiling concentrated sulphuric acid.

**Obs.**—Occurs sparingly, embedded in, or more commonly adherent to, masses of allanite and magnetite, at the northwest slope of Little Friar Mountain, Amherst Co., Virginia. Named from *Sipylus*, one of the children of Niobe, in allusion to the names niobium and tantalum.

Delafontaine (C. R., **87**, 933, 1878) states that sipylite contains yttrium, erbium (in small quantities), philippium (see samarskite), and also the ytterbium of Marignac (see gadolinite, p. 510).

ADELPHOLITE. Adelfolit *N. Nordenskiöld*, Beskrifn. Finl. Min., 1855, Jb. Min., 313, 1858; *A. E. Nd.*, Öfv. Ak. Stockh., **20**, 452, 1863, Pogg., **122**, 615, 1864.

Tetragonal. Angles undetermined. H. = 3·5–4·5. G. = 3·8. Luster greasy. Color brownish yellow to brown and black. Streak white or yellowish white. Subtranslucent. A niobate of iron and manganese, containing 41·8 p. c. of metallic acids, and 9·7 p. c. of water. From Laurinmäki, in Tammela, Finland, with columbite.

---

## 3. Columbite Group. Orthorhombic.

### 525, 526. COLUMBITE—TANTALITE.

**525. Columbite.** Ore of Columbium (fr. Conn.) *Hatchett*, Phil. Tr., 1802. Columbite *Jameson*, Min., 2, 582, 1805. Columbate of Iron. Columbeisen *Germ.* Baierine (fr. Twins[3]: tw. pl. $e$ common, usually contact-twins, heart-shaped and showing a delicate feather-like striation on $a$ (f. 5), here $c\underline{c}$ = 58° 40′ and $b\underline{b}$ = 121° 20′; also penetration-twins. Further tw. pl. $q$ (0$\bar{2}$3) rare (f. 6), here $c\underline{c}$ = 118° 39′, $b\underline{b}$ = 61° 21′. Crystals short prismatic, often rectangular prisms with the pinacoids, $abc$, prominent; also thin tabular ∥ $a$; the pyramids often but slightly developed, sometimes, however, acutely terminated by $u$ (133) alone (f. 2). Also in large groups of parallel crystals, and massive.

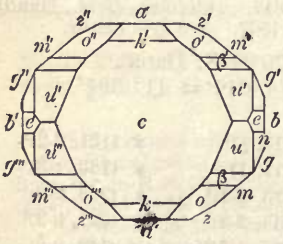
7.



Standish, Me.

Cleavage: $a$ rather distinct; $b$ less so. Fracture subconchoidal to uneven. Brittle. H. = 6. G. = 5·3–7·3, varying with the composition (see below). Luster submetallic, often very brilliant, sub-resinous. Color iron-black, grayish and brownish black, opaque; rarely reddish brown and translucent; frequently iridescent. Streak dark red to black.

**Comp., Var.**—Niobate and tantalate of iron and manganese, $(Fe,Mn)(Nb,Ta)_2O_6$, passing by insensible gradations from normal COLUMBITE, the nearly pure niobate, to normal TANTALITE, the nearly pure tantalate. The iron and manganese also vary widely. Tin and wolfram are present in small amount. The percentage composition for $FeNb_2O_6$ = Niobium pentoxide 82·7, iron protoxide 17·3 = 100; for $FeTa_2O_6$ = Tantalum pentoxide 86·1, iron protoxide 13·9 = 100.

In some varieties, *manganocolumbite* or *manganotantalite*, the iron is largely replaced by manganese. The variety from Branchville, anal. 10, corresponds to $MnNb_2O_6.MnTa_2O_6$; cf. also anal. 33. The manganotantalite of Sanarka (anal. 13) is essentially $MnTa_2O_6$.

The connection between the specific gravity and the percentage of metallic acids is shown in the following table from Marignac, Bibl. Univ., **25**, 25, 1866. See also analyses below.

[a] Other determinations gave: $Nb_2O_5$ 62·25, 61·98, 62·03; $Ta_2O_5$ 16·31, 17·12, 16·55, respectively.

The following are analyses by W. P. Headden (Am. J. Sc., **41**, 89, 1891) chiefly of columbite from the Black Hills, S. Dakota. Anals. 14–21 are all from the Etta mine, and show well the variation in the metallic acids, even in specimens from a single locality (also shown in specimens from Haddam and Bodenmais); further the accompanying variation in specific gravity.

**Pyr., etc.**—For *tantalite* B.B. unaltered. With borax slowly dissolved, yielding an iron glass, which, at a certain point of saturation, gives, when treated in R.F. and subsequently flamed, a grayish white bead; if completely saturated becomes of itself cloudy on cooling. With salt of phosphorus dissolves slowly, giving an iron glass, which in R.F., if free from tungsten, is pale yellow on cooling; treated with tin on charcoal it becomes green. If tungsten is present the bead is dark red, and is unchanged in color when treated with tin on charcoal. With soda and niter gives a greenish blue manganese reaction. On charcoal, with soda and sufficient borax to dissolve the oxide of iron, gives in R.F. metallic tin. Decomposed on fusion with potassium bisulphate in the platinum spoon, and gives on treatment with dilute hydrochloric acid a yellow solution and a heavy white powder, which, on addition of metallic zinc, assumes a smalt-blue color; on dilution with water the blue color soon disappears (Kbl.).

For *columbite* nearly as with tantalite. Von Kobell states that when decomposed by fusion with caustic potash, and treated with hydrochloric and sulphuric acids, it gives, on the addition of zinc, a blue color much more lasting than with tantalite; and the variety dianite, when similarly treated, gives, on boiling with tin-foil, and dilution with its volume of water, a sapphire-blue fluid, while, with tantalite and ordinary columbite, the metallic acid remains undissolved. The variety from Haddam, Ct., is partially decomposed when the powdered mineral is evaporated to dryness with concentrated sulphuric acid, its color is changed to white, light gray, or yellow, and when boiled with hydrochloric acid and metallic zinc it gives a beautiful blue. The remarkably pure and unaltered columbite from Arksut-fiord in Greenland is also partially decomposed by sulphuric acid, and the product gives the reaction test with zinc, as above.

**Obs.**—Occurs at Rabenstein, near Zwiesel, and Bodenmais, Bavaria, in granite, with iolite and magnetite; at Tirschenreuth, Bavaria; at Craveggia, Italy; at Tammela, in Finland; at Chanteloube, near Limoges, in pegmatyte with tantalite; near Miask, in the Ilmen Mts., with samarskite; in the gold-washings of the Sanarka region in the Ural; at Hermanskär, near Björskär, in Finland; in Greenland, in cryolite, at Ivigtut (or Evigtok), in brilliant crystals; disseminated through or among the wolframite of Auvergne, and detected by acting with aqua-regia, which dissolves the wolframite and leaves untouched the columbite (Phipson, Ch. News, 160, 1867); at Montevideo, S. A.; San Roque, Argentine Republic.

In the United States, in *Maine*, at Standish, in splendent crystals in granite; also at Stoneham with cassiterite, etc. In *N. Hampshire*, at Plymouth, with beryl; at Acworth, at the mica mine. In *Mass.*, at Chesterfield, some fine crystals, associated with blue and green tourmaline and beryl, in a vein of albitic granite; also Beverly; Northfield, Mass. (anal. 12), with beryl. In *Connecticut*, at Haddam, 2 m. from the village, in a granite vein, some of the crystals several pounds in weight; also at the chrysoberyl locality, but not now accessible; also at the iolite locality, Haddam; near Middletown, in a feldspar vein in fine crystals, some very large; at Branchville, Fairfield Co., in a vein of albitic granite, in large crystals and aggregates of crystals, sometimes weighing many pounds, also in minute thin tabular crystals translucent (*manganocolumbite*, anal. 10) implanted upon spodumene; also at other points in the neighborhood of Branchville in granite veins. In *N. York*, at Greenfield, with chrysoberyl. In *Penn.*, Mineral Hill, Delaware Co. In *Virginia*, Amelia Co., in fine splendent crystals with microlite, monazite (p. 728), etc. In *N. Carolina*, with samarskite crystals in parallel position at the Wiseman's mica mines of Mitchell Co.; also at the Deake mine and other points; Ray's mine in Yancey Co.; Balsam Gap in Buncombe Co.; near Franklin, Macon Co.; White Plains, Alexander Co. In *Colorado*, on microcline at the Pike's Peak region; Turkey Creek, Jefferson Co. (11·23 MnO). In *S. Dakota*, in the Black Hills region, common in the granite veins associated with cassiterite, beryl, etc.; the crystals and crystalline groups are often large, one mass is estimated to have weighed 2000 lbs.; most abundant at the Etta and Bob Ingersoll mines; also at other points in Pennington Co; also in Nigger Hill distr., in Lawrence Co., sometimes associated with stream tin. Cf. Headden, l. c., also W. P. Blake, Am. J. Sc., **28**, 340, 1884, **41**, 403, 1891 (figures and measurements, Pfd.). In *California*, King's Creek distr., Fresno Co.

*Mangantantalite* of Nordenskiöld is from Utö, Sweden, where it occurs with petalite, lepidolite, microlite, etc. *Manganotantalite* of Arzruni is from the gold-washings in the Sanarka region in the Ural.

Massive tantalite occurs in Yancey Co., N. C.; Coosa Co., Ala.; also in the Black Hills, S. Dakota.

Also occurs in Finland, in Tammela, at Härkäsaari near Torro, associated with gigantolite and rose quartz; in Kimito, at Skogböle, in Somero at Kaidasuo, and in Kuortane at Katiala, with lepidolite, tourmaline, and beryl; in Sweden, near Falun, at Broddbo and Finbo; in France, at Chanteloube near Limoges, in pegmatyte. *Ildefonsite* is from Ildefonso, Spain, and has G. = 7·416, H. = 6–7.

The occurrence of columbite in America was first made known by Mr. Hatchett's examination of a specimen sent by Governor Winthrop to Sir Hans Sloane, then President of the Royal Society, which was labeled as found at Neatneague (better Naumeag). Dr. S. L. Mitchill stated (Med. Repos., vol. 8) that it was taken at a spring at New London, Conn. No locality has since been detected at that place. But the rediscovery of it at Haddam, first published by Dr. Torrey (Am. J. Sc., **4**, 52, 1822), and since near Middletown, about 7 m. distant, has led to the belief that the original locality was at one of these places, which are about 30 m. N.W. of New London. Mr. J. Hammond Trumbull in a letter to Prof. Brush (July 16, 1882) discussing this subject, remarks: "The name of Namueg or Naumeag, originally given to the plantation at New London, may have been extended—as were the bounds of the plantation—east of the Thames, to the Mystic, including what is now Groton. I conjectured that the columbite was found near Winthrop's mill a short distance above the head of Mystic, and there used to be a local tradition to that effect; though it had no definite value."

The metal of columbite was named columbium by Hatchett in 1802, from Columbia, a name of America, whence his specimen was received, and thus came the name *columbite* given by Jameson and Thomson (see further below). Rose, after investigating the metal and its compounds, named it anew, calling it *niobium*, and this gave rise to the name *niobite*. *Baierite* is from the German name of Bavaria. *Torrelite* Thomson, named after Dr. J. Torrey, is the ordinary Middletown columbite; and *Greenlandite* Breith. is that from Greenland; both names originated partly in erroneous views of the crystals of the minerals. *Dianite* is the Bodenmais columbite, in which v. Kobell supposed he had discovered the acid of a new metal, which he called *dianium*.

No good reason has been given for substituting *niobium* for *columbium*, and it is contrary to the scientific law of priority; but as it is now accepted by most chemists the common usage is here followed.

Tantalite was named by Ekeberg, from the mythic Tantalus, in playful allusion to the difficulties (tantalizing) he encountered in his attempts to make a solution of the Finland mineral in acids. The name was afterward extended to the American mineral *columbite*, and to the same from other localities; while the name columbite, the metal columbium having been discovered a little prior to tantalum, received a similar extension, so as to include all tantalite.

The subsequent discovery that tantalum and columbium were distinct elements finally established them as independent species.

**Ref.**—[1] On splendent crystals from Standish, Me., Zs. Kr., **12**, 266, 1886; these results differ but little from those of J. D. D. (1837) on the Haddam mineral. The form seems to vary but little with change of composition. Analyses 1–13 (also most and probably all of 14–33) belong to minerals having the *columbite habit and angles;* even the crystals of *manganotantalite* of Arzruni (anal. 13, a manganese tantalate) show the planes *a*, *b*, *c*, *l*, *k*, *u*, *n*, and affords nearly the same ratio (below, from $ck = {}^*19° 19'$, $bu = {}^*50° 30\frac{1}{2}'$). It is plain, therefore, that skogbölite and ixiolite cannot be included in this series; their relation to normal columbite-tantalite needs further investigation (cf. below, p. 737).

The following axial ratios are interesting for comparison, although it is to be noted that the crystals seldom allow of accurate measurements. The axes of Schrauf, ref. [7] below, are based upon angles (only approximate) from crystals of different localities and are hence of no value for comparison. Schrauf made $u = 111$, $g = 110$, etc., see list, p. 737. Cf. also Kk., Min. Russl., **10**, 261, 1891.

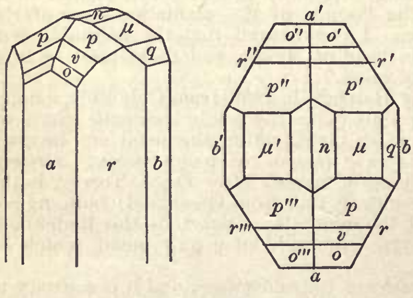
$100 \wedge 110 = 39° 14\frac{5}{6}'$, $001 \wedge 101 = 38° 33\frac{1}{6}'$, $001 \wedge 011 = 33° 4'$, N. Nordenskiöld.

**Forms:** *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$), *r* (490, *i*-$\frac{9}{4}$), *n* (016, $\frac{1}{6}$-$\breve{i}$), *μ* (011, 1-$\breve{i}$), *q* (031, 3-$\breve{i}$), *p* (111, 1), *v* (322, $\frac{3}{2}$-$\frac{\bar{3}}{2}$), *o* (211, 2-$\bar{2}$). Also *x* (131, 3-$\breve{3}$)?

Angles: $rr' = 57° 6'$, $nn' = 12° 23'$, $\mu\mu' = 66° 8'$, $qq' = 125° 47'$, $pp' = {}^*67° 28\frac{1}{2}'$, $pp'' = 91° 38\frac{1}{2}$, $pp''' = {}^*53° 58'$, $vv' = 90° 6'$, $oo' = 106° 21\frac{1}{2}'$.

Measured: $pp'' = 91° 45'$, $rr' = 57° 3$, $bq = 29\frac{1}{2}°$ (27° 7′ calc.), $nn' = 12°$, $vv' = 90°$, $oo' = 110°$.

1. 2.



Figs. 1, 3, *Skogbölite*, N. Nd.

In prismatic crystals (f. 1) the angle of the prism near that of yttrotantalite and samarskite.

Cleavage indistinct. Fracture uneven. H. = 6·0–6·5. G. = 7·8–8·0. Luster metallic. Color black. Opaque. Streak blackish brown to cinnamon-brown.

**Comp.**—Essentially $FeTa_2O_6$, a nearly pure iron tantalate. Cf. anal. 7, p. 734.

**Obs.**—From Härkäsaari in Tammela, Finland, associated with rose quartz and gigantolite, in albitic granite. Also with ixiolite at Skogböle in Kimito. This is the mineral ordinarily called tantalite, and regarded as isomorphous with columbite (Rose, Rg. et al.), but in fact as shown by the author having quite a different though related form. Cf. ref. [1].

A mineral from Pisek, Bohemia, referred to tantalite by Vrba (Zs. Kr., **15**, 201, 1889), is later stated to be only rutile, cf. Gdt., Index, **3**, 185, 1891.

**Ixiolite** *A. E. Nordenskiöld*, Pogg., **101**, 632, 1857. Kimito-tantalit *N. Nordenskiöld.* Ixionolit *F. J. Wiik.* Kassiterotantal *Hausm.* Cassitero-tantalite.

Orthorhombic. Axes $\acute{a} : \bar{b} : \acute{c} = 0·5508 . 1 . 1 2460$ A. E. Nordenskiöld.
$100 \wedge 110 = 28° 50\frac{3}{4}'$, $001 \wedge 101 = 66° 9\frac{1}{4}'$, $001 \wedge 011 = {}^*51° 15'$.

**Forms:** *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$), *c* (001, *O*); *m* (110, *I*), *s* (103, $\frac{1}{3}$-$\bar{i}$)? tw. pl.; *n* (011, 1-$\breve{i}$), *t* (031, 3-$\breve{i}$), *p* (111, 1). Angles: *mm‴* = 57° 41½′, *cs* = 37° 1′, *nn′* = 102° 30′, *tt′* = 150° 3′, *cp* = *68° 50′, *pp′* = 109° 32′, *pp‴* = 53° 28′.

Crystals rectangular prisms (*a b c*), sometimes twins with *s* (103) as tw. pl. Fracture uneven to subconchoidal. Brittle. H. = 6–6·5. G. = 7·0–7·1. Luster submetallic. Color blackish gray to steel-gray. Powder brown.

In composition a niobo-tantalate of iron and manganese, containing also a small amount of tin (anal. 11, p. 734). An analysis by Nordenskiöld gave 13 p. c. tin dioxide, but this is not confirmed by Rg. (Min. Ch., 357, 1875).

From Skogböle in Kimito, Finland. Named from *Ixion*, a mythological person related to Tantalus.

*Relation of Skogbölite and Ixiolite to Columbite-tantalite.* That there is a certain relation between the forms of columbite and the above two kinds of tantalite has been shown by various authors; it is exhibited in the following axial ratios starting from the axes of each given above:

| | | | |
|---|---|---|---|
| Columbite | | $\breve{a} : \bar{b} : \acute{c}$ | = 0·8285 : 1 : 0·8898 |
| Skogbölite | 1. | $a : b : \frac{4}{3}c$ | = 0·8170 : 1 : 0·8681 |
| | or | | |
| | 2. | $\frac{2}{3}b : a : c$ | = 0·8160 : 1 : 0·7969 |
| Ixiolite | 1. | $\frac{4}{9}b : a : \frac{1}{3}c$ | = 0·8069 : 1 : 0·7541 |
| | or | | |
| | 2. | $\frac{3}{2}a : b : \frac{2}{3}c$ | = 0·8262 : 1 : 0·8307 |

In 1 under both skogbölite and ixiolite the occurring prism (like samarskite in angle) has the symbol (490), in 2 the symbol (320) of columbite—the symbols of the other planes are in general less simple, and the value of this comparison is doubtful.

Groth proposes to retain Schrauf's position for columbite, while doubling the *ă* and *ć* axes, giving for columbite (Standish) and tantalite-skogbölite:

| | | |
|---|---|---|
| Columbite | $\breve{a} : \bar{b} : \acute{c}$ | = 0·8047 : 1 : 0·7159 |
| Tantalite-skogbölite | $\breve{a} : \bar{b} : \acute{c}$ | = 0·8170 : 1 : 0·6511 |

The similarity, however, is more apparent than real, for nearly all the prominent planes of each species are wanting on the other, and the habit is very different—moreover, true tantalite corresponds exactly with columbite in both habit and angle.

The following table shows the planes of tantalite-skogbölite common to columbite with the symbols in the positions of Dana, Schrauf and Groth; also the prominent planes of each species (those in parentheses not having been observed).

| | Dana. | Columbite Schrauf. | Groth. | | Tantalite-skogbölite N. Nd. |
|---|---|---|---|---|---|
| *a* | 100 | 010 | 010 | *b* | 010 |

**Mengite.** Ilmenite *Brooke*, Phil. Mag., **10**, 187, 1831. Mengit *G. Rose*, Reis. Ural, **2**, 83, 1842.

Occurs in short prisms terminated by a pyramid. The angles are nearly those of columbite and Des Cloizeaux states (priv. contr.) that there can be no doubt that it is really that species. The planes are then *a*, *m*, *g*, *u*; angles *gg′* = 43° 40′, *uu′* = 78° 50′, *uu‴* = 29° 28′ Brooke

G. = 5·43. Color black. Occurs in small crystals embedded in the albite of the granite veins in the Ilmen mountains. Named *mengite*, after Menge, the discoverer of the mineral. The mengite of Brooke is monazite.

HERMANNOLITE *C. U. Shepard*, Am. J. Sc., **50**, 90, 1870; **11**, 140, 1°76. A mineral from Haddam, Conn., probably identical with columbite. Cf. Hermann, who found in it "hypotantalic acid," hypoilmenic acid, etc., J. pr. Ch., **13**, 386, 1876; further Delafontaine, Am. J. Sc., **13**, 390, 1877, also Min., 5th Ed., 3d App., p. 30.

FERRO-ILMENITE *Hermann*, J. pr. Ch., **2**, 118, 1870. A kind of columbite from Haddam, Connecticut.

**527. TAPIOLITE.** Tapiolit *A. E. Nordenskiöld*, Öfv. Ak. Stockh., **20**, 445, 1863. Tantalite (fr. Sukula) *Arppe*, Act. Soc. Fenn., **6**, 590, 1861.

Tetragonal. Axis $\dot{c} = 0·6464$; 001 ∧ 101 = 32° 52¾′ Nordenskiöld.

**Forms:** *a* (100, *i-i*); *m* (110, *I*); *e* (101, 1-ĭ); *p* (111, 1), *c* (001, *O*)

Angles: *ee′* = 45° 9′, *pp′* = 56° 59½′ *pp″* = *84° 52′. The form is very near that of rutile, cassiterite, and zircon.

In square octahedrons, often monoclinic in appearance by distortion.

Cleavage not distinct. H. = 6. G. = 7·36 Nd.; 7·496 Rg. Luster strong adamantine, approaching metallic. Color pure black. Opaque.

**Comp.**—A tantalate and niobate of iron, having the same composition as tantalite, $Fe(Ta,Nb)_2O_6$ = (Ta : Nb = 4 : 1), Tantalum pentoxide 73·9, niobium pentoxide 11·1, iron protoxide 15·0 = 100.

**Anal.**—Rg., Ber. Ak. Berlin, 181, 1871. For earlier analyses see 5th Ed., p. 519.

| | $Ta_2O_5$ | $Nb_2O_5$ | $SnO_2$ | FeO | MnO |
|---|---|---|---|---|---|
| G. = 7·496 | 73·91 | 11·22 | 0·48 | 14·47 | 0·81 = 100·89 |

**Pyr.**, etc.—B.B. behaves like tantalite, but gives no reaction for manganese.

**Obs.**—Occurs near the Kulmala farm, in the village of Sukula, in the parish of Tammela, Finland, in white pegmatyte granite, with beryl, tourmaline, and arsenopyrite.

Named from an ancient Finnish divinity.

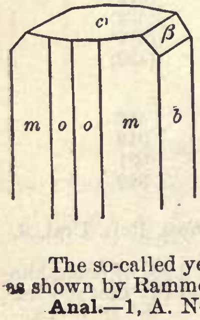
## 4. Samarskite Group. Orthorhombic.

**528. YTTROTANTALITE.** Yttrotantal *Ekeberg*, Ak. H. Stockh., **23**, 80, 1802. Tantale oxidé yttrifère *H.*, Tr., 1822. Yttroilmenit *Herm.*, J. pr. Ch., **38**, 119, 1846. Schwarzer Yttrotantalit.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·54115 : 1 : 1·1330$ A. E. Nordenskiöld[1].
100 ∧ 110 = 28° 25⅙′, 001 ∧ 101 = 64° 28⅙′, 001 ∧ 011 = 48° 34′.

**Forms:** *b* (010, *i*-ĭ), *c* (001, *O*); *o* (210, *i*-2̄), *m* (110, *I*), *p* (120, *i*-2̆), *q* (150, *i*-5̆); *s* (201, 2-ī); *β* (011, 1-ĭ).

Angles: *oo‴* = 30° 17′, *mm‴* = 56° 50′, *pp′* = 85° 28′, *bq* = *20° 17′, *ss′* = 153° 8′, *ββ′* = 97° 8′, *bβ* = *41° 26′.



Crystals prismatic, often six-sided with *m*, *b* prominent; also tabular ∥ *b*.

Cleavage: *b* very indistinct. Fracture small conchoidal. H. = 5–5·5. G. = 5·5–5·9. Luster submetallic to vitreous and greasy. Color black, brown, brownish yellow, straw-yellow. Streak gray to colorless. Opaque to subtranslucent.

**Comp.**—Essentially $\overset{\text{II}}{R}\overset{\text{III}}{R}_2(Ta,Nb)_4O_{15} + 4H_2O$, according to Rammelsberg, with $\overset{\text{II}}{R}$ = Fe,Ca, $\overset{\text{III}}{R}$ = Y,Er,Ce, etc. The water may be secondary.

The so-called yellow yttrotantalite of Ytterby and Kårarfvet belongs to fergusonite (p. 729) as shown by Rammelsberg.

**Anal.**—1, A. Nd., l. c. 2, Rg., Min. Ch., 360, 1875, also Pogg., **150**, 200, 1873.

**Pyr., etc.**—In the closed tube yields water, turns yellow. On intense ignition both varieties become white. B.B. infusible. With salt of phosphorus dissolves with at first a separation of a white skeleton of tantalic acid, which with a strong heat is also dissolved; gives a glass faintly tinted rose-red from the presence of tungsten. Not decomposed by acids. Decomposed on fusion with potassium bisulphate, and when the product is boiled with hydrochloric acid metallic zinc gives a pale blue color to the solution which soon fades.

**Obs.**—Occurs in Sweden at Ytterby, near Vaxholm, in red feldspar; at Finbo and Broddbo, near Falun, embedded in quartz and albite, associated with garnet, mica, and pyrophysalite.

The name *yttrotantalite* alludes to the composition. *Yttroilmenite* was given to a variety by Hermann upon the discovery in it of his *supposed* new metal ilmenium.

**Ref.**—[1] Öfv. Ak. Stockh., **17**, p. 28, 1860, or Pogg., **111**, 280, 1860.

**529. SAMARSKITE.** Uranotantal *H. Rose*, Pogg., **48**, 555, 1839. Samarskit (Uranniobit), *H. Rose*, Pogg., **71**, 157, 1847. Yttroilmenit *Herm.*, J. pr. Ch., **42**, 129, 1847, **44**, 216, 1848. Eytlandite *Adam*, Tabl. Min., 31, 1869.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·54565 : 1 : 0·51780$ E. S. Dana[1].

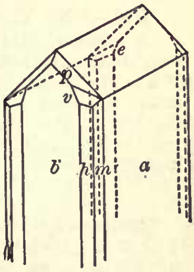
$100 \wedge 110 = 28° \ 37\frac{1}{6}'$, $001 \wedge 101 = 43° \ 30'$, $001 \wedge 011 = 27° \ 22\frac{1}{2}'$.

**Forms:** *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$); *m* (110, *I*), *h* (120, *i*-$\breve{2}$); *e* (101, 1-$\bar{i}$); *p* (111, 1); *v* (231, 3-$\frac{3}{2}$).

Angles: *mm'''* = 57° 14', *hh'* = *85°, *ee'* = *87°, *pp'* = 80° 14½', *pp''* = 94° 28', *pp'''* = 41° 10', *bp* = 69° 25', *vv'* = 91° 33', *bv* = 54° 5½'.

Crystals rectangular prisms (*a*, *b*), with *e* (101) prominent, also prismatic ‖ $\bar{b}$ by development of *e*, sometimes tabular ‖ *a* or ‖ $\breve{b}$. Faces rough and not allowing of exact measurement. Commonly massive, and in flattened embedded grains.

Cleavage: *b* imperfect. Fracture conchoidal. Brittle. H. = 5–6. G. = 5·6–5·8. Luster vitreous to resinous, splendent. Color velvet-black. Streak dark reddish brown. Nearly opaque.



Mitchell Co., N. C.

**Comp.**—$\overset{II}{R}_3\overset{III}{R}_2(Nb,Ta)_6O_{21}$ according to Rg., with $\overset{II}{R}$=Fe, Ca, $UO_2$, etc.; $\overset{III}{R}$ = cerium and yttrium metals chiefly.

[a] YO. [b] MgO. [c] Sp. grav. 5·77.

Examination of the earths contained in samarskite from North Carolina: J. L. Smith ("mosandrum"), C. R, **87**, 146, 148, 831, 1878. Delafontaine (terbium), Bibl. Univ., **61**, 273, 1878; id. (decipium, phillipium), ib., 3, 246, 250, 1880; C. R., **93**, 63. 1881. Same subject discussed by Marignac, Bibl. Univ., 3, 413, 1880; Roscoe, J. Ch. Soc., **41**, 277, 1882.

**Pyr., etc.**—In the closed tube decrepitates, glows like gadolinite, cracks open, and turns black, and is of diminished density. B.B. fuses on the edges to a black glass. With borax in O.F. gives a yellowish green to red bead, in R.F. a yellow to greenish black, which on flaming becomes opaque and yellowish brown. With salt of phosphorus in both flames an emerald-green bead. With soda yields a manganese reaction. Decomposed on fusion with potassium bisulphate, yielding a yellow mass which on treatment with dilute hydrochloric acid separates white tantalic acid, and on boiling with metallic zinc gives a fine blue color. Samarskite in powder is also sufficiently decomposed on boiling with concentrated sulphuric acid to give the blue reduction test when the acid fluid is treated with metallic zinc or tin.

**Obs.**—Occurs in reddish brown feldspar, with crystallized æschynite and columbite (and sometimes in parallel position with the latter) in the Ilmen mountains, near Miask in the Ural. The largest pieces met with were of the size of hazel-nuts.

In the United States, rather abundant and sometimes in large masses, up to 20 lbs., at the Wiseman mica mine in Mitchell Co., N. Carolina, it is intimately associated with columbite; also at the Grassy Creek mine, Mitchell Co., and in McDowell Co. Sparingly at Middletown, Conn.; also at Jones Falls, Baltimore, Md.; a related mineral in Colorado (see below). Also in Berthier Co., Quebec. Canada.

Named after the Russian, v. Samarski.

**Alt.**—An altered samarskite from Mitchell Co., N. C., called "euxenite" by Smith has yielded the following results: 1, Smith, l. c. 2, W. H. Seamon, Ch. News, **46**, 205, 1882.

| | $Nb_2O_5$ | $SnO_2,WO_3$ | $UO_3$ | $Y_2O_3$ | $Ce_2O_3$ | $(Di,La)_2O_3$ | CaO | FeO | MnO | $H_2O$ | |

**Ref.**—[1] No. Carolina, Am. J. Sc., **11**, 201, 1876.

A mineral related to samarskite has been found in the granitic débris of Devil's Head Mt., Douglas Co.. Colorado. In small fragments up to the size of a chestnut, with faint suggestions of a crystalline form. Fracture subconchoidal. Very brittle. H. = 5·5–6. G. = 6·18. Luster vitreous. Color pitch-black, pale brown in thin splinters. Streak dirty brown. Slightly soluble in hydrochloric acid. B.B. becomes dull but does not fuse. Composition given in 1. Another sample (anal. 2) had a salmon-colored streak; a third (3) seemed to be much altered. Analyses, W. F. Hillebrand, Proc. Col. Sc. Soc., **3**, 38, 1888.

NOHLITE *A. E. Nordenskiöld*, G. För. Förh., **1**, 7, 1872.

Massive. Fracture uneven. Brittle. H. = 4·5–5·0. G. = 5·04. Luster vitreous. Color black-brown. Streak brown. Opaque. Analysis:

$Nb_2O_5$ 50·43, $ZrO_2$ 2·96, UO 14·43, $Y_2(Er_2)O_3$ 14·36, $Ce_2O_3$ 0·25, FeO 8·09, CaO 4·67, MnO,MgO 0·28, CuO 0·11, $H_2O$ 4·62 = 100·20.

B.B. fuses quietly on the edges to a dull glass. Decrepitates slightly in giving off its water. With borax easily dissolved, giving a bead colored by uranium. Easily decomposed by warm sulphuric acid.

Found in a feldspar quarry at Nohl, near Kongelf, Sweden. One fragment, weighing 297 grams, seemed to be a portion of a mass at least 20 times as great.

VIETINGHOFITE *v. Lomonosov—Damour*, Bull. Ac. St. Pet., **23**, 463. 1877.

Essentially a ferruginous variety of samarskite. Amorphous. H. = 5·5–6. G. = 5·53. Color black, dull. Streak brown. Luster submetallic. Easily decomposed by $H_2SO_4$. An analysis by Damour gave:

$Nb_2O_5$ 51 00, $TiO_2$ 1·84, $ZrO_2$ 0·96, $U_2O_3$ 8·85, $Y_2O_3$ 6·57, $Ce_2(Di,La)_2O_3$ 1·57, FeO 23·00, MnO 2·67, MgO 0·83, ign. 1·80 = 99·09. Locality near Lake Baikal, eastern Siberia.

**530. ÅNNERÖDITE.** *W. C. Brögger*, G. För. Förh., **5**, 354, 1881. Aannerödite.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}82572 : 1 : 0{\cdot}89434$ Brögger.
$100 \wedge 110 = 39° 32\frac{5}{6}'$, $001 \wedge 101 = 47° 17'$, $001 \wedge 011 = 41° 48\frac{1}{2}'$.

**Forms:**
*a* (100, *i*-ī)
*b* (010, *i*-ĭ)
*c* (001, *O*)
*z* (530, *i*-$\frac{5}{3}$)
*m* (110, *1*)
*g* (130, *i*-3̆)
*l* (106, $\frac{1}{6}$-ī)
*k* (103, $\frac{1}{3}$-ī)
*e* (021, 2-ĭ)
*o* (111, 1)
*β* (233, 1-$\frac{3}{2}$)
*u* (133, 1-3̆)
*s* (263, 2-3̆)
*n* (163, 2-6̆)

$zz'' = 52° 43'$ $kk' = 39° 42'$ $cn = 61° 16'$ $uu''' = 80° 8\frac{1}{2}'$
$mm''' = 79° 6'$ $ee' = 121° 35'$ $oo' = 77° 50'$ $ss''' = 110° 49'$

$ll' = 20° 28'$ $cu = 43° 58'$ $oo''' = 62° 29'$ $au = 74° 56'$

Twins: tw. pl. *z* (530); also *e* (021). In prismatic crystals of varied habit, often closely resembling columbite; planes sometimes developed according to monoclinic symmetry. In angles near columbite, also polycrase. Many crystals often grouped in parallel position, thus forming an apparently single crystal of considerable size.

Fracture subconchoidal. Brittle. H. = 6. G. = 5·7 of anhydrous crystals. Luster submetallic to greasy submetallic. Color black. Streak dark blackish brown to brownish or greenish gray. Opaque, or translucent in very thin splinters

**Comp.**—Essentially a pyro-niobate of uranium and yttrium; formula doubtful, the water is probably not essential.

**Anal.**—C. W. Blomstrand.

Neglecting the silica, the formula calculated by Blomstrand is $R_2Nb_2O_7 + 2\frac{1}{2}H_2O$, which makes it nearly identical with samarskite, and also to the less certain nohlite (p. 740), except in the water; Brögger, however, shows that the water is not essential, but is due to a partial alteration which is accompanied by a lowering of the hardness (to 4·5) and specific gravity (to 4·28), and a loss of luster. A crystal with G. = 5·7 showed only a trace of water. The mineral is consequently hardly to be separated from samarskite in composition, but it is different in form.

**Pyr.**—Fuses B.B. with difficulty. Brögger remarks that ånnerödite (also euxenite and polycrase) bears much the same relation to columbite that samarskite does to tantalite (skogbölite); the two last being very near in form, as are ånnerödite and columbite.

**Obs.**—From the pegmatyte vein at Ånneröd, near Moss, Norway, where it is associated with monazite, alvite (p. 487), apatite, magnetite, beryl, topaz, and other minerals.

**531. HIELMITE.** Hjelmit *A. E. Nordenskiöld*, Öfv. Ak. Stockh., **17**, 34, 1860, Pogg., **111**, 279, 286, 1860.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}4645 : 1 : 1{\cdot}0264$ Weibull[1].
$100 \wedge 110 = 24° 54\frac{5}{6}'$, $001 \wedge 101 = 65° 39'$, $001 \wedge 011 = 45° 44\frac{3}{4}'$.

**Forms:** *m* (110, *1*), *p* (230, *i*-$\frac{3}{2}$), *r* (101, 1-ī), *q* (201, 2-ī).

Angles: $mm''' = 49° 50'$, $pp' = 69° 44'$, $rr' = 131° 18'$, $qq' = 154° 30'$, $qq'' = {*}25° 30'$. $mq = {*}27° 48'$.

Crystals usually rough and indistinct. Massive, without apparent cleavage. H. = 5. G. = 5·82. Luster metallic. Color pure black. Streak grayish black.

**Comp.**—A stanno-tantalate (and niobate) of yttrium, iron, manganese, calcium; formula doubtful.

Anal. 3 gives $4RO.3Ta_2O_5.2H_2O$, but the material was considerably altered.

**Anal.**—1, Nd., l.c. 2, Rg., Ber. Ch. Ges., 926, 1870. 3, 4, M. Weibull, G. För. Förh., **9**, 371, 1887.

[a] $UO_3$.

**Pyr., etc.**—In the closed tube decrepitates and yields water. B.B. infusible, but turns brown in O.F. With salt of phosphorus easily dissolved to a bluish green glass. With borax dissolves to a clear glass, which remains unchanged on flaming. With soda on charcoal gives metallic spangles (Nordenskiöld).

**Obs.**—From the Kårarfvet mine, near Falun, Sweden, along with garnet, pyrophysalite, gadolinite, asphaltum, in a pegmatyte granite.

Named for the Swedish chemist, P. J. Hjelm (1746–1813).

**Ref.**—[1] G. För. Förh., **9**, 371, 1887.

---

## Æschynite Group. Orthorhombic.

**532. ÆSCHYNITE.** Æschynit *Berz.*, JB., **9**, 195, 1828. Dystomes Melan-Erz *Mohs*, Min , 459, 1839.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0·48665 : 1 : 0·67366$ Koksharov[1].
$100 \wedge 110 = 25° 57'$, $001 \wedge 101 = 54° 9\frac{1}{3}'$, $001 \wedge 011 = 33° 58'$.

**Forms**[1]:
*b* (010, *i*-ĭ)
*c* (001, *O*)
*m* (110, *I*)
*t* (350, *i*-$\frac{5}{3}$)[3]
*r* (120, *i*-2̆)
*n* (130, *i*-3̆)[2]
*d* (101, 1-ī)[2]
*v* (021, 2-ĭ)

[a] Also $\frac{4}{4}$ $Nb_2O_5$ 57·6, $TiO_2$ 42·4 = 100, or $Nb_2O_5$ 29·64, $TiO_2$ 21·81 = 51·45.

**Pyr., etc.**—In the open tube yields water and traces of fluorine. B.B. in the forceps swells up and changes its color from black to a rusty brown. In borax dissolves easily in O.F., giving a yellow bead while hot, and on cooling becomes colorless; in R.F. with tin gives a blood-red bead. More difficultly soluble in salt of phosphorus; with a small amount of the assay gives a colorless bead, while with a larger quantity there separates a white substance which clouds the bead; in R.F., with tin on charcoal, yields an amethystine glass (Berzelius). Decomposed on fusion with potash; yields reactions similar to those mentioned under euxenite (Kobell). It is also sufficiently decomposed by sulphuric acid to show the reduction test with zinc.

**Obs.**—From Miask in the Ilmen Mts., in feldspar with mica and zircon; also with euclase in the gold sands of the Orenburg District, Southern Ural. From Hitterö, Norway (Bgr., l. c.) in a pegmatyte vein. In the granite of Königshain, Silesia.

Named from *αἰσχυνη*, *shame*, by Berzelius, in allusion to the inability of chemical science, at the time of its discovery, to separate some of its constituents.

**Ref.**—[1] Min. Russl., 3, 384, 1858; see also earlier, Brooke, Phil. Mag., 10, 188, 1831; Rose, Reis. Ural, 2, 70, 1842; Dx., Ann. Mines, 2, 349, 1842; and later, Bgr., Zs. Kr., 3, 481, 1879. Bgr. obtained for Hitterö crystals, $\breve{a} : \bar{b} : \grave{c} = 0·4816 : 1 : 0·6725$.

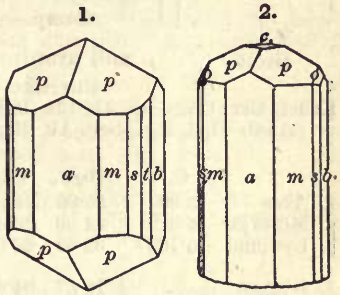
## 533. POLYMIGNITE. *Berzelius*, Ak. H. Stockh., 338, 1824.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c} = 0·71213 : 1 : 0·51207$ Brögger[1].
$100 \wedge 110 = 35° 27\frac{1}{3}'$, $001 \wedge 101 = 35° 43\frac{1}{6}'$, $001 \wedge 011 = 27° 7'$.

**Forms**[1]: *c* (001, *O*) *s* (120, *i*-$\breve{2}$) *v* (232, $\frac{3}{2}$-$\breve{\frac{3}{2}}$)
*a* (100, *i*-$\bar{i}$) *l* (210, *i*-$\bar{2}$) *t* (140, *i*-$\breve{4}$) *o* (131, 3-$\breve{3}$)
*b* (010, *i*-$\breve{i}$) *m* (110, *I*) *p* (111, 1)

The pyramid *p* (111) corresponds nearly in angle to *u* (133) of columbite.

*ll‴* = 39° 12′ *pp″* = *45° 9′ *vv‴* = 63° 54′
*mm‴* = 70° 55′ *pp‴* = 82° $52\frac{1}{2}'$ *oo′* = 42° 50′
*ss′* = 70° 9′ *vv′* = 59° 23′ *oo″* = 102° $33\frac{1}{2}'$
*tt′* = 38° 41′ *vv″* = 92° 55′ *oo‴* = 118° 57′
*pp′* = *65° $14\frac{1}{2}'$



Figs. 1, 2, Norway; 1, Rose; 2, Bgr.

Crystals slender prisms, vertically striated.

Cleavage: *a*, *b* in traces. Fracture perfect conchoidal. H. = 6·5. G. = 4·77–4·85. Luster submetallic, brilliant. Color black. Streak dark brown. Opaque.

**Comp.**—A niobate and titanate (zirconate) of the cerium metals, iron, calcium. Brögger calculates $5RTiO_3.5RZrO_3.R(Nb,Ta)_2O_6$.

**Anal.**—Blomstrand, quoted by Brögger:

| $Nb_2O_5$ | $Ta_2O_5$ | $ZrO_2$ | $TiO_2$ | $ThO_2$ | $SnO_2$ | $(Y,Er)_2O_3$ | $Ce_2O_3$ | $(La,Di)_2O_3$ | $Fe_2O_3$ | FeO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 11·99 | 1·35 | 29·71 | 18·90 | 3·92 | 0·15 | 2·26 | 5·91 | 5·13 | 7·85[a] | 3·40[b] | 7·14[c] | 0·28 |

[PbO 0·39, Alk. 1·36 = 100·91

[a] Incl. 0·19 $Al_2O_3$. [b] Incl. 1·32 MnO. [c] Incl. MgO 0·16.

An early incomplete analysis was made by Berzelius, Ak. H. Stockh., 339, 1824 (5th Ed., p. 524).

**Pyr., etc.**—B.B. infusible, and unchanged in color. With borax dissolves readily, giving an iron bead; with more of the assay becomes brownish yellow on flaming, and opaque on cooling; with tin in R.F. turns reddish yellow. With salt of phosphorus not easily acted upon, gives a reddish tinge in R.F., which is unchanged by tin. With soda shows traces of manganese (Berzelius). The powdered Fredriksvärn mineral, heated with concentrated sulphuric acid, gives a whitish residue, which, treated with hydrochloric acid and tin-foil, gives a beautiful azure-blue color, indicating, as under polycrase, the presence of some other metallic acid in addition to titanic, which of itself gives only a violet color. The dilute acid solution gives with turmeric paper the orange color characteristic of zirconia.

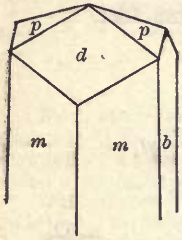
**Obs.**—Occurs at Fredriksvärn and on the island of Svenör, in Norway, with feldspar, zircon-elæolite, pyrochlore, magnetite. Its crystals sometimes exceed an inch in length. Reported from Moravia; also by Shepard as occurring at Beverly, Mass.

**Ref.**—[1] Zs. Kr., 16, 387, 1890. Earlier Rose, Pogg., 6, 506, 1826. If the axes $\breve{a}$ and $\grave{c}$ are interchanged the axial ratios of polymignite and æschynite are closely similar, the pyramid *p* corresponding to *o*; the forms are hence very near and the two may be the same species, as suggested by Frankenheim, Pogg., 91, 372, 1855, and later Rammelsberg.

**534. EUXENITE.** Euxenit *Scheerer*, Pogg., **50**, 149, 1840, **72**, 566, 1847.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0·364 : 1 : 0·303$ Groth[1].
$100 \wedge 110 = 20° 0'$, $001 \wedge 101 = 39° 46'$, $001 \wedge 011 = 16° 51'$.

**Forms**[1]: *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$); *m* (110, *I*); *d* (201, 2-$\bar{i}$); *p* (111, 1).
Angles: $mm''' = {*}40° 0'$, $dd' = {*}118° 0'$, $pp' = 77° 4'$, $pp''' = 26° 12'$.



Groth.

Crystals rare. Commonly massive.

Cleavage none. Fracture subconchoidal. Brittle. H.=6·5. G. = 4·60 Jölster, Scheerer; 4·73–4·76 Tvedestrand, id.; 4·94–4·99, ib., Breith.; 4·89–4·99 Alve, Forbes; 4·96, Chydenius. Luster brilliant, metallic-vitreous, or somewhat greasy. Color brownish black; in thin splinters a reddish brown translucence lighter than the streak. Streak-powder yellowish to reddish brown.

**Comp.**—A niobate and titanate of yttrium, erbium, cerium, and uranium; formula (Rg.) probably $\overset{\text{III}}{\text{R}}(\text{NbO}_3)_3.\overset{\text{III}}{\text{R}}_2(\text{TiO}_3)_3.\tfrac{3}{2}\text{H}_2\text{O}$.

Euxenite contaius the rare element germanium in small amount, cf. Krüss, Ber. Ch. Ges., **21**, 131, 1888.

**Anal.**—1–3, Rg., Ber. Ak. Berlin, 428, 1871. 4, Jehn, Inaug. Diss., Jena, 1871.

[a] UO.

On the absorption-spectra of rare earths in euxenite see Krüss and Nilson, Öfv. Ak. Stockh., **44**, 378, 1887.

**Pyr., etc.**—B.B. infusible. Dissolves in borax and salt of phosphorus, giving a yellow bead while hot; with salt of phosphorus shows a yellowish green (uranium reaction) on cooling, if sufficiently saturated (Scheerer). When decomposed by fusion with caustic potash, and subsequently treated with water, and this solution neutralized with hydrochloric acid, it gives a precipitate, which, boiled with concentrated hydrochloric acid and tin-foil, gives a clear sapphire-blue fluid, which changes to an olive-green, and finally bleaches. If the residue of the fusion after leaching is treated with hydrochloric acid and boiled with tin-foil it yields on dilution a pale rose-red color (Kobell). The mineral is sufficiently attacked, on evaporation with sulphuric acid, to give a whitish residue, which, treated with metallic zinc or tin, affords the characteristic blue reduction test.

**Obs.**—Occurs at Jölster in Norway, embedded in feldspar and sometimes in scaly mica, the largest crystals 2 in. long and ½ in. wide, but usually much smaller; also near Tvedestrand; at Alve, Tromö, near Arendal; at Mörefjär, near Näskilen; also Hitterö.

Named by Scheerer from εὔξενος, *friendly to strangers, hospitable,* in allusion to the rare elements it contains.

**Ref.**—[1] Arendal, Min.-Samml. Strassburg, 255, 1878; the measurements are approximate only, but agree fairly well with Breith. and Kjerulf (see Zs. Kr., 3, 483, 1879); not, however, with Dahll (Ed. N. Phil. J., 1, 63, 1855) who gives a prism of 54°, a macrodome (*r*) of 129° ($ar = 25° 30'$) and a pyramid $\alpha$, $b\alpha = 73°$.

**535. POLYCRASE.** Polykras *Scheerer*, Pogg., **62**, 430 1844.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0·3462 : 1 : 0·3124$ Brögger[1].
$100 \wedge 110 = 19° 5\tfrac{3}{4}'$, $001 \wedge 101 = 42° 3\tfrac{3}{4}'$, $001 \wedge 011 = 17° 21'$.

**Pyr., etc.**—In the closed tube decrepitates, and gives traces of water. B.B. in the forceps glows, and turns to a light grayish brown color, but is infusible. Soluble in borax, giving in O.F. a clear yellow bead, which in R.F. with tin turns brown. In salt of phosphorus gives a clear yellow glass, which on cooling is greenish; in R.F. the color becomes darker. With soda no reaction for manganese, and on charcoal no metallic particles. Decomposed by evaporation with concentrated sulphuric acid; the product, treated with hydrochloric acid, gives on boiling with metallic zinc or tin a deep azure-blue solution which does not fade. The dilute solution gives a deep orange to turmeric paper (zirconia).

**Obs.**—From Hitterö, Norway, in crystals ½ to 1½ in. long, in granite with gadolinite and orthite; at Slättåkra, parish of Alsheda, Småland, Sweden; also near Dresden.

In the U. States, occurs in well-formed prismatic crystals (G. = 4·724–4·78) in N. Carolina, in the gold-washings on Davis land, Henderson Co., with zircon, monazite, xenotime, magnetite; the crystals are altered on the exterior to a yellow substance resembling gummite. Also in S. Carolina, four miles from Marietta in Greenville Co. (G. = 4·925–5·038), about twenty miles from the N. Carolina locality.

Named from πολὺς, *many*, and κρᾶσις, *mixture*.

N. B. Möller makes the so-called polycrase of Brevik certainly, and that of Hitterö probably, identical with polymignite (J. pr. Ch., **69**, 318, 1856).

**Ref.**—[1] Zs. Kr., **3**, 484, 1879, the angles make no great claim to accuracy; Scheerer, l. c., obtained earlier *pp'''* = 28°, *mm'''* = 40°. [2] Hidden & Mackintosh, Am. J. Sc., **39**, 302, 1890, and **41**, 423, 1891; the crystals described showed some irregularity in the distribution of the planes, suggesting hemimorphism; apparent twins are mentioned with *d* (201) and *l* (011), also *u* (101) as twinning-planes.

## APPENDIX TO NIOBATES, TANTALATES.

Arrhenite *Nordenskiöld; Engström*, Inaug. Diss., Upsala, 1877.

A heterogeneous decomposition-product looking like red feldspar; occurs with fergusonite and cyrtolite at Ytterby, Sweden. G. = 3·68. Analysis:

| $Ta_2O_5$ | $Nb_2O_5$ | $SiO_2$ | $ZrO_2$ | $Fe_2O_3$ | $Al_2O_3$ | $Ce_2(Di_2,La_2)O_3$ | $Y_2O_3$ | $Er_2O_3$ | CaO | BeO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 21·28 | 2·67 | 17·65 | 3·42 | 1·87 | 3·88 | 2·59 | 22·06 | 11·10 | 5·22 | 0·74 | 6·87 | = 100·35 |

**Blomstrandite** *Lindström*, G. För. Förh., 2, 162, 1874.

Massive. H. = 5·5. G. = 4·17–4·25. Luster vitreous. Color black. Powder coffee-brown. Opaque, only translucent in very thin splinters.

Analyses:

| | $Nb_2O_5$ $Ta_2O_5$ | $TiO_2$ | UO | FeO | CaO | $H_2O$ | MgO | MnO | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 49·76 | 10·71 | 23·68 | 3·33 | 3·45 | 7·96 | 0·16 | 0·04 | $Al_2O_3$ 0·11, X[b] 0·12 = 99·32 |
| 2. | 60·77 | | 23·37 | 3·39 | 3·04 | 8·17[a] | *tr.* | 0·06 | X[b] 0·20 = 99·00 |

[a] At 100°, 2·78 (in another trial 2·65); above 100°, 5·39.

[b] Precip. by $H_2S$.

The atomic ratio of R : Nb,Ti = 1 : 2·5, and for Ti : Nb = 1 : 2·75.

B.B. fuses with difficulty. Gives off water in the closed tube. With borax in O.F. a reddish yellow, on cooling a yellow bead; in R.F. reddish brown. With salt of phosphorus in O.F. a red brown bead when hot, and yellow when cold; in R.F. reddish yellow hot, and green cold.

Found very sparingly with nohlite in a feldspar quarry at Nohl, Sweden. Named for Prof. C. W. Blomstrand of Lund.

**Rogersite** *J. L. Smith*, Am. J. Sc., 13, 367, 1877.

Massive. As a thin mammillary crust on samarskite. H. = 3·5. G. = 3·313. Color white. Analyses (approximate):

| | $Nb_2O_5$ | $Y_2O_3$, etc. | $H_2O$ | |
|---|---|---|---|---|
| 1. | 18·10 | 60·12 | 17·41 | = 95·63 |
| 2. | 20·21 | *und.* | 16·34 | |

Considered as a decomposition-product of samarskite, with which, and with hatchettolite, it occurs in Mitchell Co., N. C. Named after Prof. Wm. B. Rogers (1805–1882).

## Oxygen Salts.

## 4. PHOSPHATES, ARSENATES, VANADATES, ANTIMONATES.

[a] Molec. wght. 254·5. [b] FeO.

**Pyr., etc.**—B.B. infusible. When moistened with sulphuric acid colors the flame bluish green. Difficultly soluble in salt of phosphorus. Insoluble in acids.

**Obs.**—Occurs as an accessory mineral in granite veins; sometimes in minute embedded crystals generally distributed in granitic and gneissoid rocks. From a granite vein at Hitterö, with polycrase, malacon, and orthite, where the crystals are sometimes symmetrically compounded with crystals of zircon (E. Zschau, l. c.[2]), the two species being closely homœomorphous; also at Moss, Kragerö, and from pegmatyte veins at other points in Norway, as Narestö near Arendal; rare in the Langesund fiord region, as on the Arö reefs; at Ytterby, Sweden; the Fibia Berg, S.W. from St. Gothard; the Binnenthal in Upper Valais, Switzerland; from the granite of the Schwalbenberg near Görlitz, Silesia; Pisek, Bohemia (G. = 4·308, Vrba). Kenngott's *wiserine*, from the Binnenthal, formerly referred here, is in fact octahedrite (see p. 241).

An accessory constituent in considerable quantity of the muscovite granites of Brazil as detected by washing the decomposed or crushed rock; the localities noted are chiefly in the states Rio de Janeiro, São Paulo, Minas Geraes (cf. O. A. Derby, Am. J. Sc., **41**, 308, 1891). Observed in grayish white or pale yellow crystals in the diamond sands of Diamantinos and of Bahia (*castelnaudite*).

In the United States, in the gold washings of Clarksville, Georgia, associated with zircon, rutile, and cyanite; in McDowell Co., N. C., near Dysortville, sometimes in twisted crystals; at Mill's Gold mine, Burke Co., N. C. (in crystals compounded), also near Green River P. O., Henderson Co., and in Mitchell Co. with zircon (cyrtolite); further in brilliant crystals in Alexander Co. with rutile, etc., with tysonite near Pike's Peak, Colorado; rare on New York Island (Hidden, l. c.).

Beudant named the species *xenotime* (apparently from ξενός, *stranger to*, and τιμή, *honor*), but in the next line gives the derivation " κενός, *vain*, et τιμή, honneur," as if the word were *kenotime*, and adds afterward that his name is intended to recall the fact that the mineral was erroneously supposed by Berzelius (in 1815) to contain a new metal (the metal which he named thorium, before the later thorium was discovered). There is a sneer at the great Swedish chemist in the name, which should have occasioned its immediate rejection. Fortunately the word was misspelt from the first; and in its accepted form may be regarded as referring to the fact that the crystals are small, rare, not showy, and were long unnoticed.

[a] Metallic acids. [b] $ZrO_2$.

**Pyr., etc.**—B.B. infusible, turns gray, and when moistened with sulphuric acid colors the flame bluish green. With borax gives a bead yellow while hot and colorless on cooling; a saturated bead becomes enamel-white on flaming. Difficultly soluble in hydrochloric acid.

**Obs.**—Monazite is rather abundantly distributed as an accessory constituent of gneissoid rocks in certain regions, thus in North Carolina and Brazil (cf. Derby, Am. J. Sc., **37**, 109, 1889.

It occurs near Zlatoust in the Ilmen Mts., in granite, along with flesh-red feldspar; also near the river Sanarka, in the Ural; with zircon in gold sands of Ivalo, Finnish Lapmark. In Norway near Nöterö (*urdite*), in crystals sometimes 1 in. across; at various points near Arendal, and in pegmatyte at Ånneröd near Moss. In granite at Schreiberhau, Silesia, with gadolinite; at Schüttenhofen and Pisek, Bohemia; near the Laacher See. At Nil St. Vincent, Belgium (cf. Franck., Bull. Soc. Belg., **21**, 40, 1891). In Cornwall, England.

Found also in the gold-washings of Rio Chico, in Antioquia, in the diamond gravels of Minas Geraes, Caravellas, and Bahia, Brazil.

In the United States it is found in small crystals from $\frac{1}{16}$ to $\frac{3}{4}$ in. long, with the sillimanite of Norwich, and sparingly with the same mineral at Chester, Ct. A few minute crystals (*eremite* of Shepard) were found in a boulder of albitic granite, containing also a few minute zircons and tourmalines, in the northeastern part of Watertown, Ct.; sparingly at Portland, Ct. Good crystals have been obtained with the sillimanite of Yorktown, Westchester Co., N. Y. In large coarse crystals and masses in albitic granite with microlite, etc. (see p. 728); at Amelia Court House, Virginia. In Alexander Co., N. Carolina, in splendent crystals at Milholland's Mill; also at Stony Point in large cruciform twins with rutile, hiddenite, etc. In considerable quantities in Madison Co., N. C., yielding angular fragments due to parting ‖ *c*, *m* (with twinning striations?), probably *d* and perhaps other planes. Also in Mitchell Co., Yancey Co. In rolled grains in the gold-washings, sometimes abundant, in Burke, Polk, McDowell, and Rutherford counties; large quantities have been mined from this source for technical purposes; some 15 tons of monazite sand, containing from 60 to 92 p. c. of small crystals, have been obtained (Genth, 1891). In the mica veins of Villeneuve, Ottawa Co., Quebec.

The original *turnerite*, whose crystallographic identity with monazite was established by J. D. Dana in 1866, was from Dauphiné, probably from Le Puys, near St. Cristophe (not "Mt. Sorel," cf. Miers, Min. Mag., 8, 207, 1889); it occurs in small yellow or brown crystals with quartz, albite, octahedrite, crichtonite (ilmenite); also similarly from Santa Brigritta, Tavetsch, the Binnenthal, Laacher See, etc.

*Cryptolite* occurs in wine-yellow prisms and grains in the green and red apatite of Arendal, Norway, and is discovered on putting the apatite in dilute nitric acid; constitutes 2 or 3 p. c. of the mass; it was found especially in the red apatite, or in reddish points of the green, and associated with particles of magnetic iron, hornblende, and another cerium ore of a hyacinth-red color, supposed to be monazite. Occurs also in the apatite of the Sliudianka river in Siberia. Phosphocerite, according to Watts and Chapman, may be present in the cobalt ore of Tunaberg. The crystalline forms described as most common in the powder are an octahedron and a square or rectangular prism, terminating in a four-sided pyramid parallel with the lateral planes, resembling zircon. Genth has observed a mineral, probably cryptolite, in the Hurdstown apatite. Named from *κρυπτός, concealed.* The relations of phosphocerite are uncertain.

Mallard has shown that minute crystals inclosed in the apatite from Midbö, near Tvedestrand, are monazite, and it seems probable that all the cryptolite is of the same nature. Bull. Soc. Min., **10**, 236, 1887.

Monazite is named from *μονάζειν, to be solitary*, in allusion to its rare occurrence. *Turnerite* is named after the English chemist, E. H. Turner.

**Ref.**—[1] Milholland's Mill, Alexander Co., N. C., Am. J. Sc., **24**, 247, 1882; the axial ratios vary rather widely for different localities. Some other values of the axial ratio, in addition to that here adopted, are as follows:

| | $\grave{a} : \bar{b} : \grave{c}$ | $\beta$ | |
|---|---|---|---|
| Norwich, Conn. | 0·9742 : 1 : 0·9227 | 76° 14′ | J. D. Dana. |

Kr., **15**, 203, 1888.

KÅRARFVEITE. Korarfveite *F. Radominski*, C. R., **78**, p. 764, 1874. Occurs in albite with gadolinite, hielmite, and beryl at Kårarfet near Falun, Sweden (there called monazite). In imperfect crystals, or crystalline masses often very large; one cleavage perfect. Luster vitreous. Double refracting. G. = 4·93. Color yellow passing into brown. Translucent. Streak grayish yellow. Analysis upon impure material:

$P_2O_5$ 27·38 $(Ce,La,Di)_2O_3$ 67·40 CaO 1·24 MgO *tr.* $Fe_2O_3$ 0·32 F 4·35 $H_2O$ *tr.* = 100·69

B.B. infusible. Partially attacked by hydrochloric acid with evolution of chlorine. Blomstrand shows it to be impure monazite, G. För. Förh., **11**, 379, 1889.

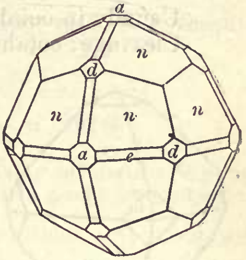
**538. BERZELIITE.** Berzeliit *Kühn*, Lieb. Ann., **34**, 211, 1840. Magnesian Pharmacolite *Dana*, Min., 239, 1844. Chaux arseniatée anhydre *Dufr.* Berzelit *Haid.*, Handb., 495, 1845. Kühnite *B. & M.*, Min., 481, 1852. Pyrrhoarsenite *L. J. Igelström*, Bull. Soc. Min., **9**, 218, 1886. Pyrrharsenite.

Isometric, rarely in trapezohedrons[1] *n* (211, 2-2) with also *a* (100, *i-i*), *d* (110, *i*), and *e* (210, *i*-2). Usually massive.

Cleavage none. Fracture subconchoidal. Brittle. H. = 5. G. = 4·07–4·09 Flink. Luster resinous. Color honey-, sulphur-, and orange-yellow; yellowish red. Streak nearly white to orange-yellow. Transparent to translucent. Optically isotropic.

**Comp.**—An orthoarsenate, $R_3As_2O_8$ with R = Ca, Mg, Mn. The relative amounts of manganese and magnesium vary widely.

In *pyrrharsenite* a little antimony takes the place of part of the arsenic.



Långban, Flink.

**Anal.**—1, Flink, l. c. 2, Hogböm, G. För. Förh., **9**, 397, 1887. 3, Igelström, Bull. Soc. Min., **9**, 28, 1886. 4, Id., Jb. Min., **1**, 48, 1889. 5–7, Hogböm, l. c.

Kühn's original analyses (5th Ed., p. 544) led to the formula $R_{10}As_6O_{25}$. He gives also G. = 2·52(!). B.B. infusible. His observations, which can hardly be entirely correct, may have been made on pseudoberzeliite.

**Pyr., etc.**—B.B. fuses easily to a black bead if rich in manganese, less readily to a gray or brown bead in other kinds. With soda on charcoal gives an arsenical odor; with soda on platinum foil fuses with effervescence, and gives a manganese reaction. Soluble in nitric acid.

*Pyrrharsenite* fuses easily to a black bead; with soda on charcoal a strong arsenical odor and some antimony fumes; with soda also a manganese reaction. Dissolves readily in acids; with sulphuric acid gives a precipitate of calcium sulphate.

**Obs.**—Occurs at Långban in Sweden, with iron ore and granular limestone, braunite, hausmannite; also the Moss mine, Nordmark, with hausmannite in crystalline limestone. Sometimes encloses a nucleus of caryinite. Named after the Swedish chemist, Berzelius (1799–1848).

*Pyrrharsenite* occurs in deep yellowish red embedded grains, with hausmannite, tephroite, also barite, calcite, at the Sjö manganese mines of Grythytte, Örebro, Sweden.

Named from πυρρός, *fire*, and *arsenic*, in allusion to its brilliant fire-red color.

**Ref.**—[1] Flink, Nyt Mag., **29**, 300, 1885. Ak. Handl. Stockh. Bihang, **12** (2), No. 2, 27, 1886; see earlier H. Sj., G. För. Förh., **2**, 533, 1875. Wichmann, Zs. Kr., **5**, 105, 1880.

PSEUDOBERZELIITE. Dubbelbrytande Berzeliit *W. Lindgren*, G. För. Förh., **5**, 552, 1881. Pseudoberzeliit *Id.*, ibid., **7**, 291, 1884. Associated with the isometric berzeliite there occurs at Långban also a doubly refracting arsenate similar in appearance and probably also having the composition $R_3As_2O_8$. If, as appears probable, it proves to be a distinct species, the above name may be retained for it.

Massive; anisotropic. No distinct cleavage. H. = 5. G. = 4·03–4·04. Color dirty yellowish white or light sulphur-yellow. Composition $R_3As_2O_8$. Anal.—L. W. McCay, G. För. Förh., **5**, 554, 1881.

| $As_2O_5$ | MnO | CaO | MgO | |
|---|---|---|---|---|
| 62·00 | 4·18 | 20·00 | 12·81 | PbO,$Fe_2O_3$ *tr.*, insol. 0·68 = 99·67 |

Occurs in a light brown fine granular mixture of calcite and manganiferous mica, often penetrated by hausmannite.

Here also seems to belong the berzeliite from the Moss mine, Nordmark, described by Igelström, G. För. Förh., **7**, 101, 1884. It occurs in veins and rounded grains. Color yellow. Optically biaxial, positive (orthorhombic?). 2E = 140°, $\rho < v$ Btd. (Bull. Soc. Min., **7**, 31, 1884). Comp. probably $R_3As_2O_8$. Analysis, Igelström, l. c.:

$As_2O_5$ 57·80  CaO 25·25  MgO(MnO *tr.*) 16·95 = 100

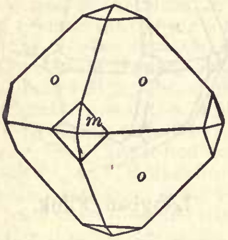
**539. MONIMOLITE.** Monimolit *L. J. Igelström*, Öfv. Ak. Stockh., **22**, 227, 1865.

Isometric. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *i*), *o* (111, 1), *m* (311, 3-3).

Usually in octahedrons, also cubic. Also massive and incrusting.

Cleavage: octahedral, indistinct. Fracture small conchoidal, splintery. Brittle. H. = 5–6. G. = 6·58; also 7·29 (cf. below). Luster greasy to submetallic. Color yellowish or brownish green, dark brown to black. Streak straw-yellow, cinnamon-brown. Translucent to nearly opaque. Isotropic, or sometimes showing slight double refraction.



Pajsberg, Flink.

**Comp., Var.**—An antimonate of lead, iron, and sometimes calcium, in part, $R_3Sb_2O_8$, with R = Pb : Fe = 3 : 1, hence: Antimony pentoxide 36·6, lead protoxide 57·2, iron protoxide 6·2 = 100. Manganese is present in small amount.

**Var.**—1. *Contains calcium* (anal. 1, 2). Octahedral with *m* (311). H. = 6. G. = 6·579. Luster greasy. Color brownish green; by transmitted light yellow-green. Not attacked by fusion with alkaline carbonates. Anal. 1 gives $4RO.Sb_2O_5$; anal. 2, $15RO.4Sb_2O_5$, with R = Pb : Fe : Ca = 5 : 2 : 5 nearly.

2. *Without calcium.* Cubic, with *o*, *d*. H. = 5. G. = 7·287. Luster submetallic. Color dark brown to black, nearly opaque. Readily decomposed by fusion with alkaline carbonates. Agrees with the formula $R_3Sb_2O_8$ given above.

These varieties are distinguished by Flink, their relation is uncertain.

**Anal.**—1, Igelström, l. c. 2, 3, Flink, l. c.

| | G. | $Sb_2O_5$ | PbO | FeO | MnO | CaO | MgO | $Na_2O$ | | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Pajsberg | 5·94 | 40·29 | 42·40 | 6·20 | | 7·59 | 3·25 | — | = | 99·73 |
| 2. " | 6·58 | 40·51 | 42·74 | 5·38 | 0·41 | 9·70 | 0·56 | 0·54 | = | 99·84 |
| 3. " | 7·29 | 38·18 | 55·33 | 5·57 | 1·16 | — | — | — | = | 100·24 |

Nordenskiöld[2] made the species tetragonal, with $\dot{c} = 0·9950$, $oo' = {}^*70° \ 23·6'$, $oo'' = 109° \ 12'$.

**Pyr., etc.**—B.B. fuses to a black slag; on charcoal gives a malleable lead-colored globule, which in O.F. gives a white coating of antimony trioxide, and nearer the assay the yellow of lead oxide. Insoluble in strong acids, or with carbonated or caustic alkalies, even on fusion, except var. 2 (cf. above). Reduced by hydrogen gas at a red heat; becomes soluble in acids.

**Obs.**—Occurs with tephroite, magnetite, and hedyphane at the Harstig mine, Pajsberg, in Wermland, Sweden. Also at Långban with tephroite and rhodonite.

Named from *μόνιμος, permanent, stable.*

**Ref.**—[1] Flink, Ak. Stockh., Bihang, **12** (2), No. 2, 35, 1887. [2] Nd., Öfv. Ak. Stockh., **27**, 550, 1870.

**540. CARYINITE.** Koryinit, Karyinit *C. H. Lundström*, G. För. Förh., **2**, 178, 223, 1874.

Massive, probably monoclinic. Cleavage in two directions at 90° (at 50° Dx.).

Fracture splintery. H. = 3–3·5. G. = 4·25. Luster greasy. Color brown to yellowish brown. Streak yellowish white. Biaxial, 2E = 41° 58′ to 47°. Dispersion $\rho > v$, also horizontal, Dx.[1]

**Comp.**—Perhaps $R_3As_2O_8$ with R = Pb, Mn, Ca, Mg.

**Anal.**—Lundström, l. c.

| $As_2O_5$ | PbO | MnO | FeO | CaO | MgO | $CO_2$ | Cl | insol. | | |

**Pyr., etc.**—B.B. fuses easily to a black slag, giving reactions for arsenic, lead, and manganese. Dissolves readily, with slight effervescence in nitric acid.

**Obs.**—Occurs intimately mixed with calcite and hausmannite and berzeliite (isotropic, A. Sj., G. För. Förh., **2**, 533, 1875; cf. Lindgren, ib., **5**, 556, 1881) at Långban, Wermland, Sweden.

Named from *καρύϊνος, nut-brown.*

**541. CARMINITE.** Carminspath *Sandberger*, Pogg., 80, 391, 1859. Karminspath. Carmine Spar. Carminite *Dana*, Min., 410, 1854.

Orthorhombic. In clusters of fine needles. Also in spheroidal forms with a columnar structure. Cleavage parallel to the faces of a rhombic prism.

H. = 2·5. G. = 4·105. Luster vitreous, but cleavage pearly. Color carmine to tile-red; powder reddish yellow. Translucent. Brittle.

**Comp.**—Perhaps $Pb_3As_2O_8.10FeAsO_4$ = Arsenic pentoxide 48·5, iron sesquioxide 28·1, lead oxide 23·4 = 100.

**Anal.**—R. Müller, on 0·068 gr., Pogg., 103, 345, 1858.

$As_2O_5$ 49·11 $Fe_2O_3$ 30·29 PbO 24·55 = 103·95

**Pyr., etc.**—B.B. on charcoal fuses easily to a steel-gray globule, giving out arsenical vapors; with soda a globule of lead, and with borax an iron reaction. Heated in a glass tube no change. Soluble in nitric acid.

**Obs.**—From the Luise mine at Horhausen, N. of Neuwied on the Rhine, with beudantite and quartz in a mine of limonite.

**542. PUCHERITE.** *A. Frenzel*, J. pr. Ch., 4, 227, 361, 1871.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·5327 : 1 : 2·3357 Websky[1].

100 ∧ 110 = 28° 2⅔′, 001 ∧ 101 = 77° 9⅙′, 001 ∧ 011 = 66° 49⅓′.

**Forms**[1]: *a* (100, $i$-$\bar{i}$), *c* (001, *O*); *m* (110, *I*); *w* (012, $\frac{1}{2}$-$\breve{i}$), *x* (011, 1-$\breve{i}$); *n* (112, $\frac{1}{2}$); *ψ* (544, $\frac{5}{4}$-$\frac{5}{4}$); *e* (122, 1-$\breve{2}$).

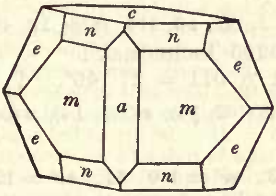
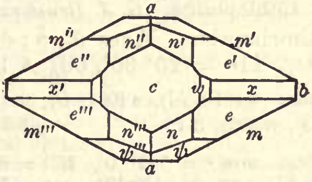
*xx′* = 133° 39′ *ce* = 72° 40′ *ee′* = 81° 35′ *ee‴* = 88° 13′

1.



2.



Schneeberg, after Websky.

Crystals small, usually tabular ∥ *c*; also acicular. Faces *e* striated ∥ edge *c/e*.

Cleavage: *c* perfect. Fracture subconchoidal. Brittle. H. = 4. G. = 6·249. Luster vitreous to adamantine. Color reddish brown. Streak yellow. Translucent to opaque.

**Comp.**—Bismuth vanadate, $BiVO_4$ or $Bi_2O_3.V_2O_5$ = Vanadium pentoxide 28·2, bismuth trioxide 71·8 = 100.

**Anal.**—1, 2, Frenzel, l. c. 3, Id., Jb. Min., 514, 1872.

| | $V_2O_5$ | $As_2O_5$ | $P_2O_5$ | $Bi_2O_3$ | | |
|---|---|---|---|---|---|---|
| 1. | 27·31 | — | — | 73·39 | = | 100·70 |
| 2. | 27·07 | — | — | 72·93 | = | 100 |
| 3. | 22·19 | 3·66 | 1·34 | 73·16 | = | 100·35 |

**Pyr., etc.**—In the closed tube decrepitates. B.B. on charcoal fuses and gives a coating of bismuth oxide, with soda yields a globule of metallic bismuth. With salt of phosphorus a chrome-green bead in R.F., becoming light yellow in O.F. (vanadium). Soluble in hydrochloric acid with evolution of chlorine to a deep-red solution, which on dilution becomes green and deposits a yellow basic chloride.

**Obs.**—Found at the Pucher Mine, Schneeberg, Saxony, on quartz associated with bismite and asbolite. Also at the Arme Hilfe mine, at Ullersreuth, near Hirschberg, Voigtland, on ocherous limonite with bismuthinite, native bismuth, etc.; at the mine Sosaer Glück, at Sosa, near Eibenstock.

**Artif.**—Obtained by Frenzel by the desiccation (over $H_2SO_4$) of a solution containing bismuth nitrate and vanadium chloride. Jb. Min., 680, 1875.

**Ref.**—[1] Min. Mitth., 245, 1872.

### 543, 544. TRIPHYLITE—LITHIOPHILITE:

**543. Triphylite.** Triphylin *Fuchs*, J. pr. Ch., **3**, 98, 1834, **5**, 319, 1835. Tetraphylin *Berz.*, Årsb., **15**, 1835. Perowskyn *N. Nordenskiöld.*

**544. Lithiophilite.** *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **16**, 118, 1878; **18**, 45, 1879.

Orthorhombic. Axes ă : b̄ : ċ = 0·4348 : 1 : 0·5265 Tschermak[1].
100 ∧ 110 = 23° 30′, 001 ∧ 101 = 50° 27′, 001 ∧ 011 = 27° 46′.

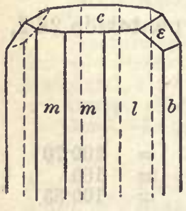
**Forms:** *b* (010, *i*-ĭ), *c* (001, *O*); *m* (110, *I*), *l* (120, *i*-2̆); *w* (102, ½-ī), *e* (101, 1-ī), *v* (302, $\frac{3}{2}$-ī); *ϵ* (021, 2-ĭ), *n* (031, 3-ĭ).

Angles: *mm‴* = *47° 0′, *ll‴* = 82° 1′, *ww′* = 62° 23′, *ee′* = 100° 54′, *vv′* = 122° 20′, *ϵϵ′* = 92° 57½′, *nn′* = 115° 19½′, *me* = *45° 0′, *mϵ* = 73° 12′.

Crystals rare, usually coarse and faces uneven. Commonly massive, cleavable to compact.

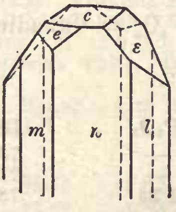
Cleavage: *c* perfect; *b* nearly perfect; *m* interrupted. Fracture uneven to subconchoidal. H. = 4·5–5. G. = 3·42–3·56. Luster vitreous to resinous. Color greenish gray, bluish in triphylite; also salmon-color, honey-yellow, yellowish brown, light clove-brown in lithiophilite; often nearly black on the surface. Pleochroism distinct, for lithiophilite: ‖ ă deep pink, ‖ b̄ faint pink, ‖ ċ pale greenish yellow, E. S. D., l. c. Streak uncolored to grayish white. Transparent to translucent.

1.



Norwich.

2.



Bodenmais.

Optically +. Ax. pl. ‖ *c*. Bx ⊥ *b*. $2H_{a.r} = 74° 45′$, $2H_{a.bl} = 79° 30′$.

**Comp., Var.**—A phosphate of iron, manganese, and lithium, $Li(Fe,Mn)PO_4$, varying from the bluish gray TRIPHYLITE with little manganese to the salmon-pink or clove-brown LITHIOPHILITE with but little iron.

Typical *Triphylite* is $LiFePO_4$ or $Li_3PO_4.Fe_3P_2O_8$ = Phosphorus pentoxide 45·0, iron protoxide 45·5, lithia 9·5 = 100.

Typical *Lithiophilite* is $LiMnPO_4$ or $Li_3PO_4.Mn_3P_2O_8$ = Phosphorus pentoxide 45·3, manganese protoxide 45·1, lithia 9·6 = 100.

**Anal.**—1–4, S. L. Penfield, Am. J. Sc., **13**, 425, 1877, **17**, 226, **18**, 47, 1879. 5, H. L. Wells, ib., **16**, 118, 1878. For earlier analyses see 5th Ed., p. 542.

[a] Incl. $K_2O$, 0·32. [b] X = gangue.

**Pyr., etc.**—In the closed tube sometimes decrepitates, turns to a dark color, and gives off traces of water. B.B. fuses at 1·5, coloring the flame beautiful lithia-red in streaks, with a pale bluish green on the exterior of the cone of flame. The coloration of the flame is best seen when the pulverized mineral moistened with sulphuric acid is treated on a loop of platinum wire. With the fluxes reacts for iron and manganese, the iron reaction is feeble in pure lithiophilite. Soluble in hydrochloric acid.

**Obs.**—*Triphylite* occurs at Rabenstein, near Zwiesel, in Bavaria; also at Keityö, in Finland (perowskine or tetraphyline); Norwich, Mass.; also with spodumene at Peru, Me., Grafton, N.H.

Named from *τρίς, threefold,* and *φυλή, family,* in allusion to its containing three phosphates.

*Lithiophilite* occurs at Branchville, Fairfield Co., Conn., in a vein of albitic granite, in irregular masses intimately associated with spodumene (and cymatolite, q.v.), also with eosphorite, triploidite, rhodochrosite, uraninite; the masses are sometimes very large and occasionally there are rough crystals with the forms; also at Tubbs' Farm, Norway, Me. Named from *lithium* and *φιλός, friend.*

**Alt.**—Triphylite and triplite, like other minerals containing manganese protoxide, undergo easy alteration by oxidation and hydration; and the former also by losing its alkalies. The iron shown in some analyses (cf. sarkopside, p. 778) is thus accounted for. The following have come from the alteration of one or the other of these minerals.

A. HETEROSITE. Heteposite *Alluaud*, in an Art. by *Vauquelin*, Ann. Ch. Phys., **30**, 294, 1825. Heterosite, Heterozite, *Alluaud*, Ann. Sc. Nat., **8**, 346, 1826.

Cleavable, massive and lamellar; cleavage stated to be in three directions, unequal, affording an oblique prism of 80°. H. = 5·5–6; G. = 3·52, or 3·39 after further alteration, Dufrénoy; luster resinous, or like that of apatite; color greenish and bluish gray, becoming violet and submetallic on exposure. Soluble in acids, with a slight residue of silica. B.B. fuses to a deep brown submetallic enamel. Found in pegmatyte near Limoges, Dept. of Haute Vienne, France, and especially at the quarries of Hureaux. Named *heterosite* from *ἕτερος, other* or *different*, but misspelt by Vauquelin.

B. PSEUDOTRIPLITE *Blum*, Orykt., 2 Aufl., 537, with anal. by Delffs. Resembles triplite; but occurs incrusting triphylite at Rabenstein, Bavaria, to the alteration of which its formation is owing.

C. ALLUAUDITE *Damour*, Ann. Mines, **13**, 341, 1848 [not Alluaudite *Bernhardi*]. In nodules, or massive, with three rectangular cleavages, two of these rather easy, the other less so. H. = 4–5; G. = 3·468. Color brown, brownish red at the edges by transmitted light; powder brownish yellow. B.B. fuses easily to a black magnetic globule. Dissolves in hydrochloric acid with evolution of chlorine. Supposed to be altered triplite, and comes from Chanteloube, near Limoges.

Anal.—1–4 of altered triphylite, 5, 6, altered lithiophilite. 1, Rg., Pogg., **85**, 439, 1852. 2, Fuchs, l. c. 3, Dmr., l. c. 4, J. W. Mallet, Am. J. Sc., **18**, 33, 1854. 5, F. P. Dewey, ib., **17**, 367, 1879. 6, H. L. Wells, ib., p. 368. Other analyses, 5th Ed., p. 543.

**Ref.**—[1] Ber. Ak. Wien, **47** (1), 282, 1863. Cf. J. D. D., Am. J. Sc., **11**, 100, 1851.

A phosphate near triphylite has been described by W. P. Headden (Am. J. Sc., **41**, 416, 1891) from the "Nickel Plate" tin mine, Pennington Co., S. Dakota. It occurs in nodules associated with spodumene and beryl. Cleavage in two directions, one perfect, the other imperfect. Fracture uneven to subconchoidal. H. = 5. G. = 3·612. Luster greasy to vitreous. Color dark green. Transparent to translucent in thin splinters. Anal.—

| | $P_2O_5$ | FeO | MnO | CaO | MgO | $Na_2O$ | $K_2O$ | $Li_2O$ | F | ign. | gangue |
|---|---|---|---|---|---|---|---|---|---|---|---|

Formula deduced $4\overset{\text{I}}{R}_3PO_4.9\overset{\text{II}}{R}_3P_2O_8$.

MELANCHLOR *Fuchs*, J. pr. Ch., **17**, 171, 1839. A hydrous iron phosphate from Rabenstein, occurring on triphylite and probably derived from its alteration. The name alludes to its blackish green color.

## 545. NATROPHILITE. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., 39, 205, 1890.

Orthorhombic, near triphylite in form; measured angles: $mm''' = 50° 30'$, $ll''' = 87°$, $ce = 47°–49°$. Chiefly massive, cleavable.

Cleavage: *c* perfect; *b* much less so; *m* interrupted. Fracture uneven to conchoidal. Brittle. H. = 4·5–5. G. = 3·41. Luster resinous to nearly adamantine, on *c* somewhat pearly. Color deep wine-yellow. Transparent to translucent. Optically +. Ax. pl. ∥ *c*. Bx ⊥ *b*.

**Comp.**—Sodium-manganese phosphate, $NaMnPO_4$ or $Na_3PO_4.Mn_3P_2O_8$ = Phosphorus pentoxide 41·1, manganese protoxide 41·0, soda 17·9, = 100.

**Anal.**—H. L. Wells, l. c.

| | $P_2O_5$ | MnO | FeO | $Na_2O$ | $Li_2O$ |
|---|---|---|---|---|---|
| $\frac{3}{3}$ | 41·03 | 38·19 | 3·06 | 16·79 | 0·19 $H_2O$ 0·43, insol. 0·81 = 100·50 |

**Pyr., etc.**—B.B. fuses easily, coloring the flame intensely yellow. Reacts for manganese with the fluxes. Soluble in acids.

**Obs.**—Occurs rather sparingly at Branchville, Fairfield Co., Connecticut, closely associated with the corresponding lithium-manganese phosphate, lithiophilite. It may have been derived from the alteration of it, analogous to the changes which the lithium silicate, spodumene, has undergone at the same locality (cf. p. 368).

---

## 546. BERYLLONITE. *E. S. Dana*, Am. J. Sc., 36, 290, 1888. *E. S. Dana* and *H. L. Wells*, ibid., 37, 23, 1889.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·57243 : 1 : 0·54901 E. S. Dana.

$100 \wedge 110 = 29° 47' 17''$, $001 \wedge 101 = 43° 48' 13''$, $001 \wedge 011 = 28° 46' 2''$.

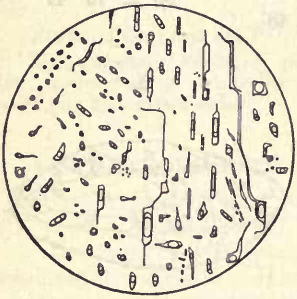
|---|---|---|---|
| Red, Li | 1·5492 | 1·5550 | 1·5604 |
| Yellow, Na | 1·5520 | 1·5579 | 1·5608 |
| Green, Tl | 1·5544 | 1·5604 | 1·5636 |

8.



**Comp.**—A phosphate of beryllium and sodium, $NaBePO_4$ or $Na_3PO_4.Be_3P_2O_8$ = Phosphorus pentoxide 55·9, beryllium oxide, 19·7, soda 24·4 = 100.

**Anal.**—H. L. Wells, l. c.

| $P_2O_5$ | BeO | $Na_2O$ | ign. |
|---|---|---|---|
| 55·86 | 19·84 | 23·64 | 0·08 = 99·42 |

**Pyr.**—Decrepitates somewhat and fuses about 3 to a slightly clouded glass, coloring the flame deep yellow with a green streak on the lower edge. Slowly but completely soluble in hot acids.

**Obs.**—Found loose among the disintegrated material of a granitic vein, at Stoneham, Maine; associated with feldspars, smoky quartz, beryl, columbite. The same region has yielded herderite and phenacite.

The crystals of beryllonite often show a columnar structure due to the presence of hollow canals and fluid cavities arranged parallel to the vertical axis. Other cavities (with liquid $H_2O,CO_2$) are present often in great numbers (f. 8). The natural faces are often delicately etched on *c*, showing minute depressions nearly square in outline.

**Artif.**—On the artificial formation of beryllonite, see Ouvrad, C. R., **110**, 1334, June 23, 1890.

### 547. HERDERITE.

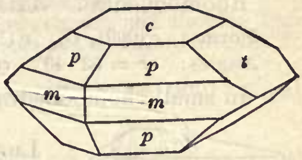
4.



4, Ehrenfriedersdorf.

Crystals sometimes resembling a low hexagonal pyramid (f. 4); also short prismatic in direction of axis ǎ.

Cleavage: *m* interrupted. Fracture subconchoidal. H = 5. G. = 2·99–3·01; 3·012, a perfectly transparent crystal from Stoneham, Penfield. Luster vitreous, inclining to subresinous. Color various shades of yellowish and greenish white. Translucent.

Optically –. Ax. pl. ∥ *b*. Bx ⊥ *à*. Dispersion $\rho > v$. Axial angles, Dx.[5]:

| | | | |
|---|---|---|---|
| Maine | $2E_r$ = 121° 44′ Li | $2E_y$ = 121° 22′ Na | $2E_{bl}$ = 120° 33′ $CuSO_4$ |
| " | $2H_{a.r}$ = 72° 34′ glass | $2H_{a.y}$ = 72° 12′ | $2H_{a.bl}$ = 71° 24′ |
| " | $2E_r$ = 120° 21′ | $2E_y$ = 119° 45′ | $2E_{bl}$ = 119° 11′ |

Also for yellow $\alpha = 1·592$, $\beta = 1·612$, $\gamma = 1·621$ Btd.

| | | | | |
|---|---|---|---|---|
| Saxony | $2H_{a.r}$ = 74° 18′ | $2H_{a.y}$ = 74° 4′ | $2H_{o.r}$ = 105° 11′ | ∴ $2V_r$ = 74° 29′ |
| " | $2E_r$ = 124° 35′ | $2E_y$ = 124° 18′ | $2H_{o.y}$ = 105° 23′ | ∴ $2V_y$ = 74° 16′ |

**Comp.**—A fluo-phosphate of beryllium and calcium, $(CaF)BePO_4$, with the fluorine in part replaced by hydroxyl. If F : OH = 1 : 1, this requires: Phosphorus pentoxide 43·8, beryllium oxide 15·4, lime 34·6, fluorine 5·9, water 2·8 = 102·5, deduct 2·5 (O = 2F) = 100. If fluorine alone were present the amount would be 11·7 p. c.

Groth includes herderite in the Olivenite Group, cf. Tab. Ueb., pp. 75, 76, 1889.

**Anal.**—1, Mackintosh, Am. J. Sc., **27**, 135, 1884. 2, Genth, Am. Phil. Soc., **21**, 694, 1884. 3, Penfield and Harper, Am. J. Sc., **32**, 107, 1886.

Analyses of the herderite from Ehrenfriedersdorf and from Stoneham by Winkler, made on minute quantities, have been shown to be untrustworthy; he gave considerable alumina and overlooked the fluorine, Jb. Min., 2, 134, 1884.

**Pyr., etc.**—B.B. phosphoresces with an orange-yellow light, fuses with difficulty, becomes white and opaque; takes a blue with cobalt solution; gives acid water in the closed tube when strongly heated. Dissolves in acids.

**Obs.**—The original herderite is known only from a few specimens obtained prior to 1825 at the tin mines of Ehrenfriedersdorf, Saxony; the crystals described by Haidinger resemble apatite in form (f. 4). $pp'''$ = 38° 43′ herderite, $xx'$ = 37° 44′ apatite.

Discovered in 1883 at Stoneham, Maine (see Hidden, Am. J. Sc , 27, 73, 135, 1884). It occurs in a granitic ledge in isolated crystals and in clusters implanted on quartz crystals, or embedded in them; also on muscovite and associated with albite; found sparingly with tourmaline at Auburn, Me.; also at Hebron.

Named after Baron von Herder, director of the Saxon mines. The name *glucinite* was suggested (Hidden, l. c.) for the Stoneham mineral in the idea that it might prove to differ from the Saxon in containing beryllium (glucinum) in place of aluminium, but the identity of the minerals from the two localities has been thoroughly proved.

**Ref.**—[1] Stoneham, Am. J. Sc., **27**, 229, 1884. Haidinger gives for Ehrenfriedersdorf: $pp'$ = 63° 57′, $pp'''$ = 38° 43′. [2] Ehrenfriedersdorf only, Haid., l. c. [3] Stoneham only, E. S. D., l. c. [4] Stoneham, Hidden, *ibid.*, **32**, 209, 1886. [5] Dx., Bull. Soc. Min., **7**, 130, 1884; Btd., **9**, 141, 1886.

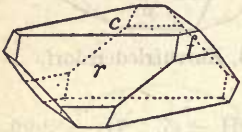
**548. HAMLINITE.** *W. E. Hidden* and *S. L. Penfield*, Am. J. Sc., **39**, 511, 1890.

Rhombohedral. Axis $\dot{c} = 1{\cdot}1353$; $0001 \wedge 10\bar{1}1 = 52° \ 39\tfrac{5}{6}'$ Penfield.

**Forms:** $c$ (0001, $O$), $r$ ($10\bar{1}1$, R), $f$ ($02\bar{2}1$, $-2$).

Angles: $cr = 52° \ 40'$, $cf = 69° \ 7\tfrac{1}{2}'$, $rr' = {}^*87° \ 2'$, $ff' = 108° \ 2'$, $rf = 54° \ 1'$.

In small rhombohedral crystals with basal plane prominent.



Cleavage: basal, perfect. H. = 4·5. G. = 3·228. Luster on $c$ pearly; on rhombohedral faces greasy to resinous. Colorless and transparent, or with a slight yellow tint. Optically +; double refraction not strong.

**Comp.**—A phosphate of aluminium or beryllium (or both) with water and fluorine; exact composition undetermined.

**Pyr., etc.**—B.B. fuses about 4 to a white porcelain-like mass coloring the flame green. In the closed tube gives off water abundantly and fluorine which etches the glass. Slowly soluble in acids, giving a solution which reacts strongly for phosphoric acid. The presence of aluminium (or beryllium) and absence of calcium were proved by qualitative test.

**Obs.**—Occurs very sparingly at Stoneham, Me., associated with the beryllium phosphate, herderite, and the beryllium silicate, bertrandite. Only a single specimen has thus far been found.

Named after Dr. A. C. Hamlin of Bangor, Me., author of a work on precious stones.

---

### 3. Apatite Group. Hexagonal with pyramidal hemihedrism.

Phosphates, Arsenates, Vanadates of calcium and lead, with chlorine or fluorine.

General formula $R_5(F,Cl)[(P,As,V)O_4]_3 = (R(F,Cl))R_4[(P,As,V)O_4]_3$;

Also written $3R_3(P,As,V)_2O_8.R(F,Cl)_2$. Here R=Ca or Pb, also Mn.

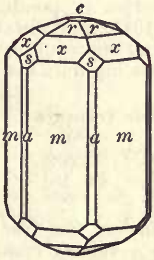
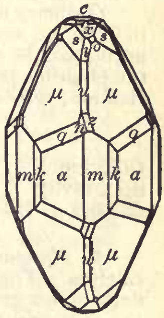
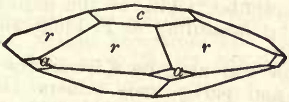
3.



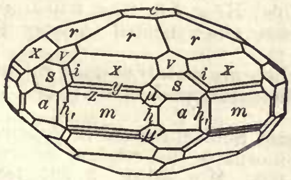
4.



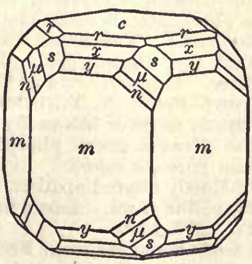
5.



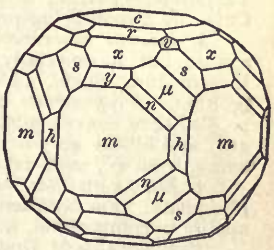
6.



7.



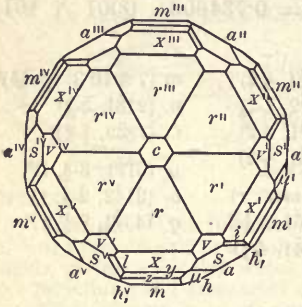
8.



Figs. 1, 2, Common forms. St. Lawrence Co., N. Y., and Canada. 3, 6, Alexander Co., N. C., Hidden and Washington[13]. 4, Paris, Me.[9] 5, Hebron. 7, Branchville, Conn., Pirsson. 8, St. Gothard, Haidinger.

Crystals varying from long prismatic to short prismatic and tabular; in the latter cases often highly modified; also in low pyramids (f. 5); rarely terminated by a pyramid of the third series (f. 4). Also globular and reniform, with a fibrous or imperfectly columnar structure; massive, structure granular to compact.

9.



Alexander Co., N. C., basal section of f. 6.

Cleavage: *c* imperfect; *m* more so. Fracture conchoidal and uneven. Brittle. Etching-figures conform to the pyramidal hemihedrism[14]. H. = 5, sometimes 4·5 when massive. G. = 3·17–3·23 cryst. Luster vitreous, inclining to subresinous. Streak white. Color usually sea-green, bluish green; often violet-blue; sometimes white; occasionally yellow, gray, red, flesh-red, and brown. Transparent to opaque. A bluish opalescence sometimes in the direction of the vertical axis, especially in white varieties. Some colored varieties pleochroic; absorption $\epsilon > \omega$.

Optically —. Double refraction weak. Sometimes abnormally biaxial (cf. Mld.[15]). Indices, Heusser[16]:

| Fraunhofer lines | D | E | F | G |
|---|---|---|---|---|
| $\omega$ | 1·64607 | 1·64998 | 1·65332 | 1·65953 |
| $\epsilon$ | 1·64172 | 1·64543 | 1·64867 | 1·65468 |

**Var.**—1. *Ordinary.* Crystallized, or cleavable and granular massive. Colorless to green, blue, yellow, flesh-red. (*a*) The *asparagus-stone*, originally from Murcia, Spain, is yellowish green, as the name implies. *Moroxite*, from Arendal, is in greenish blue and bluish crystals. Both names have been used for apatite of the same shades from other places. (*b*) *Lasurapatite* is a sky-blue variety; it occurs in crystals with lapis-lazuli in Siberia. (*c*) *Francolite*, from Wheal Franco, near Tavistock, Devonshire, occurs in small crystalline stalactitic masses, grayish green to brown, and in minute curving crystals (anal. 11).

Ordinary apatite is *fluor-apatite*, containing fluorine often with only a trace of chlorine, up to 0·5 p. c.; rarely the chlorine preponderates, and sometimes fluorine is entirely absent. The normal angle, *cx* ($0001 \wedge 10\bar{1}1$), and also the specific gravity seem to diminish with increase of the chlorine percentage, but more observations are needed to establish this (Kk., Pusirevsky, Baumh., ref. [1]). The following data are brought together by Baumhauer:

| | Schwarzenstein | Tokovaya | Sulzbach | Rothenkopf | Sliudianka | Blagodatsk | Achmatovsk |
|---|---|---|---|---|---|---|---|
| Chlorine | *tr.* | 0·01 | 0·028 | 0·085 | 0·109 | 0·22 | 0·51 |
| Sp. gravity | 3·215 | 3·202 | 3·153 | 3·149 | 3·178 | 3·132 | 3·091 |
| *cx* ($0001 \wedge 10\bar{1}1$) | 40° 17′ | 40° 18⅛′ | 40° 15½′ | 40° 10¾′ | — | 40° 16⅙′ | 40° 6⅛′ |

2. *Manganapatite* (Siewert, Zs. Nat. Halle, **10**, 339, 1874) contains manganese replacing calcium. The original is a variety from San Roque, near Córdoba, Argentine Republic, color dark bluish green, containing 6·7 p. c. MnO, anal. 26. For other occurrences, which have proved to be not uncommon, see anals. 27–33. The dark green apatite from Dixon's quarry, Wilmington, Del., also contains considerable manganese (Genth, priv. contr.).

*Cupro-apatite* Adam, Tabl. Min., 45, 1869. From near Coquimbo, Chili, at the mines of Tambillos, occurring in clear turquoise-blue crystals, containing, according to F. Field, 20·93 CuO, the copper being present as phosphate; it needs confirmation.

3. *Fibrous, concretionary, stalactitic.* The name *Phosphorite* was used by Kirwan for all apatite, but it especially included the fibrous concretionary and partly scaly mineral from Estremadura, Spain, and elsewhere. It has H. = 4·5; G. = 2·92–3 Forbes, but 2·98–3·12 after ignition. *Eupyrchroite*, from Crown Point, N. Y., belongs here; it is concentric in structure, consisting of convex subfibrous layers, more or less easily separable; H. = 4·5; G. = 3·053; ash-gray and bluish gray in color, and gives a green phosphorescence when heated (whence the name, from *εὖ, well, πῦρ, fire*, and *χρόα, a color*).

4. *Earthy apatite; Osteolite.* Mostly altered apatite. Coprolites are mainly impure calcium phosphate. For both see beyond, p. 768 *et seq.* Lasne finds sedimentary phosphates to be fluor-apatite in composition, C. R., **110**, 1376, 1890.

*Pseudoapatite* of Breithaupt from Kurprinz, near Freiberg, and Schlackenwald in Bohemia, has been called pseudomorphous apatite. Frenzel makes pyromorphite the original mineral, analysis: $P_2O_5$ 39·28, CaO 56·66, $SO_3$ 1·42, $CO_2$ [2·64], Cl *tr.* = 100. Min. Mitth., 3, 364, 1880.

*Staffelite* of Stein (Jb. Min., 716, 1866) occurs incrusting the phosphorite of Staffel, in botryoidal, reniform, or stalactitic masses, fibrous and radiating. H. = 4. G. = 3·128. Color leek to dark green, greenish yellow. See anal. 37. Stein regards it as a result of the action of carbonated waters on phosphorite.

**Comp.**—For *Fluor-apatite* $(CaF)Ca_4P_3O_{12}$; for *Chlor-apatite* $(CaCl)Ca_4P_3O_{12}$; also written $3Ca_3P_2O_8 + CaF_2$ and $3Ca_3P_2O_8 + CaCl_2$. There are also intermediate compounds containing both fluorine and chlorine. The percentage composition for these normal varieties is as follows:

| | | | | | | |
|---|---|---|---|---|---|---|
| *Fluor-apatite* | $P_2O_5$ 42·3 | CaO 55·5 | F 3·8 = 101·6 | or $Ca_3P_2O_8$ 92·25 | $CaF_2$ 7·75 | = 100 |
| *Chlor-apatite* | $P_2O_5$ 41·0 | CaO 53·8 | Cl 6·8 = 101·6 | or $Ca_3P_2O_8$ 89·4 | $CaCl_2$ 10·6 | = 100 |

In the formula as first (and more correctly) written the univalent group (CaF) or (CaCl) takes the place of one hydrogen atom in the acid $3H_3PO_4 = H_9P_3O_{12}$.

Some analyses give results at variance with this normal composition, showing a deficiency in the fluorine and chlorine: thus Voelcker proposes to write the formula $3Ca_3P_2O_8.\left\{\begin{matrix} CaF_2 \\ CaCl_2, \\ CaO \end{matrix}\right.$ and Hoskyns-Abrahall gives $Ca_{10}(PO_4)_6(O,F_2,Cl_2)$. Cf. Groth, Tab. Ueb., 74, 1889.

Fluor-apatite is much more common than the other variety; here belongs the apatite of the Alps, Spain, St. Lawrence Co., N. Y., Canada. Apatites in which chlorine is prominent are rare; this is true of some Norwegian kinds. An apatite from Kragerö contained 4·10 chlorine and no fluorine, Voelcker, J. pr. Ch., **75**, 384, 1858, while others gave 1·38 and 1·03. See also analyses below. Varieties also occur in which the calcium is largely replaced by manganese, as in *manganapatite*. Further Cossa (Trans. Acc. Linc., **3**, 17, 1878) has noted the presence of didymium (also Ce,La) in many apatites as proved by absorption bands in the spectrum; these elements have been found before by chemical means, but usually referred to enclosed cryptolite. Scheerer found 5 p. c. cerium oxide in the apatite of the augite-syenite of southern Norway, which is *not* due to enclosed cryptolite—cf. Bgr., Zs. Kr., **16**, 70, 1890.

**Anal.**—G. Rose first detected the fluorine and chlorine, and published the following as the composition of different specimens (Pogg., **9**, 185, 1827):

| | 1. Snarum | 2. Murcia | 3. Arendal | 4. Greiner | 5. St. Gothard |
|---|---|---|---|---|---|
| | G. = 3·174 | G. = 3·235 | G. = 3·222 | G. = 3·175 | G. = 3·197 |
| Calcium phosphate | 91·13 | 92·066 | 92·189 | 92·16 | 92·31 |
| Calcium chloride | 4·28 | 0·885 | 0·801 | 0·15 | *tr.* |
| Calcium fluoride | 4·59 | 7·049 | 7·01 | 7·69 | 7·69 |

The following are other typical analyses; some earlier ones are given in 5th Ed., p. 532.

1–7, Hoffmann, Rep. G. Surv. Canada, 1 H., 1879. 8, 9, Voelcker, Inaug. Diss., Giessen, 1883. 10, Rowan, Ch. News, **50**, 208, 1884. 11, Maskelyne and Flight, J. Ch. Soc., **24**, 3, 1871. 12, Klement, Bull. Mus. Belg., **5**, 159, 1888. 13–15, Hoskyns-Abrahall, Inaug. Diss., Munich, 1889. 16, Sachsse, after deducting impurities, quoted by Stelzner, Jb. Min., **1**, 265, 1889. 17, Schertel, ibid. 18, Nikolayev, Zs. Kr., **11**, 391, 1886; also other anals. of massive varieties with 3·05 to 1·87 p. c. Cl. 19–24, Voelcker, l. c. 25, Waage, quoted by Brögger and Reusch, Zs. G. Ges., **27**, 674, 1875; also another anal. with 3·5 p. c. Cl.

For further analyses of phosphorite see references above.

The oxygen equivalent of the fluorine (chlorine) is to be deducted from the above analyses. Anal. 20, 21 are from different parts of the same crystal. From 16, 17, impurities have been deducted.

**Pyr., etc.**—B.B. in the forceps fuses with difficulty on the edges (F. = 4·5–5), coloring the flame reddish yellow; moistened with sulphuric acid and heated colors the flame pale bluish green (phosphoric acid); some varieties react for chlorine with salt of phosphorus, when the bead has been previously saturated with copper oxide, while others give fluorine when fused with this salt in an open glass tube. Gives a phosphide with the sodium test.

Dissolves in hydrochloric and nitric acid, yielding with sulphuric acid a copious precipitate of calcium sulphate; the dilute nitric acid solution gives with lead acetate a white precipitate, which B.B. on charcoal fuses, giving a globule with crystalline facets on cooling. Some varieties of apatite phosphoresce on heating.

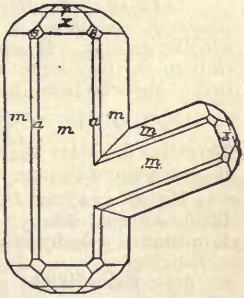
**Obs.**—Apatite occurs in rocks of various kinds and ages, but is most common in metamorphic crystalline rocks, especially in granular limestone, granitic and many metalliferous veins, particularly those of tin, in gneiss, syenite, hornblendic gneiss, mica schist, beds of iron ore; occasionally in serpentine; common in igneous or volcanic rocks in the form of microscopic acicular crystals which have been early formed in the crystallization from the magma; sometimes in ordinary stratified limestone, beds of sandstone or shale of the Silurian, Carboniferous, Jurassic, Cretaceous, or Tertiary. It has been observed as the petrifying material of wood.

Among its localities are Ehrenfriedersdorf in Saxony; Schwarzenstein, Rothenkopf, Pfitsch in the Tyrol; with epidote on the Knappenwand, Untersulzbachthal; St. Gothard, Tavetsch, etc., in Switzerland; Mussa-Alp in Piedmont, white or colorless, and of like form and color on the Mittaghorn in Upper Valais; Zinnwald and Schlackenwald in Bohemia; in England, in Cornwall, with tin ores; in Cumberland, at Carrock Fells, in celandine-green crystals in gilbertite; in Devonshire, cream-colored at Bovey Tracey, and at Wheal Franco (*francolite*); in Ireland, in a basaltic dike near Kilroot in Antrim, also in Down, Dublin, and Killiney Hill. The greenish blue variety, called *moroxite*, occurs at Arendal, Snarum, and Kragerö in Norway, at the latter place in part flesh-red, and looking much like feldspar; with magnetic iron of a greenish yellow color at Mt. Blagodatsk in the Ural; with black tourmaline on the Shaitanka in Ekaterinburg; on the Sliudianka (*lasurapatite*); at the emerald mine of the Takovaja, 85 versts N.E. of Ekaterinburg; on the Kiräba, 70 versts S.W. of Miask, containing *no* chlorine (Pusirevsky), with G. = 3·126; in Pargas, Finland. The *asparagus-stone* or *spargelstein* of Jumilla, in Murcia (not C. de Gata), Spain, is pale yellowish green in color; a variety from Zillerthal is wine-yellow; a similar variety is obtained from the Cerro de Mercado, Durango, Mexico. The *phosphorite*, or massive radiated variety, is obtained abundantly near the junction of granite and argillyte, in Estremadura, Spain; at Schlackenwald in Bohemia; at Amberg, Bavaria, in Jurassic limestone, nodular and stalactitic; Nassau, etc.

Large quantities of apatite are mined in Norway at Kragerö, where it was worked as early as 1854; also at Ödegaard, near Bamle, Norway, with enstatite and wagnerite (kjerulfine) in large crystals; further in veins at many points along the southern coast from Langesund fiord to Arendal, in part in connection with the so-called "geflecter gabbro" mentioned on pp. 467, 472, in which a triclinic feldspar has been largely altered to scapolite.

In *Maine*, on Long Island, Blue-hill Bay, in veins 10 in. wide, intersecting granite. In *N. Hamp.*, crystals, often large, are abundant, 4 m. S. of the N. village meeting-house, Westmoreland, in a vein of feldspar and quartz, in mica slate, along with molybdenite; fine crystals at Piermont, in white limestone, on the land of Mr. Thomas Cross. In *Mass.*, crystals occasionally 6 in. long, at Norwich (N.E. part), in gray quartz; at Bolton abundant, the forms seldom interesting; sparingly at Chesterfield, Chester, Sturbridge, Hinsdale, and Williamsburgh. In *Conn.*, at Branchville, dark greenish blue (*manganapatite*), also in greenish white and colorless crystals, highly modified and resembling the Swiss, in short pearly white prisms with rough basal planes; at Leete's quarry, near Stony Creek. In *New York*, large crystals of apatite are found in St. Lawrence Co., in granular limestone, with scapolite, titanite, etc., at Hammond, Gouverneur; in Rossie, with titanite and pyroxene, 2 m. N. of the village of Oxbow; also on the bank of Vrooman Lake, Jefferson Co., in white limestone; Sanford mine, East Moriah, Essex Co., in magnetite, which is often thickly studded with six-sided prisms; at the iron mine, Brewster, Putnam Co.; near Edenville, Orange Co., asparagus-green, in white limestone; in the same region, blue, grayish green, and grayish white crystals; 2 m. S. of Amity, emerald- and bluish green crystals; at Long Pond, Essex Co., with garnet and vesuvianite; fibrous mammillated (*eupyrchroite*) at Crown Point, Essex Co., about a mile south of Hammondsville, in large quantities, quarried for agricultural purposes. In *New Jersey*, on the Morris Canal, near Suckasunny, of a brown color, in massive pyrrhotite; with the magnetite of Bryam mine; Mt. Pleasant mine near Mt. Teabo, in a low hill near the junction of Rockaway R. and Burnt Meadow Cr., ¾ m. from the canal, in masses sometimes 6 in. through; at Hurdstown, Sussex Co., where a shaft has been sunk and the apatite mined; masses brought out weigh occasionally 200 lbs., and some cleavage prisms have the planes 3 in. wide. In *Penn.*, at Leiperville, Delaware Co.; in Chester Co., at New Garden; in Bucks Co., at Southampton, manganesian, Genth. In *Maryland*, near Baltimore. In *Delaware*, at Dixon's quarry, Wilmington, of a rich blue color. In *N. Carolina*, in highly modified clear yellow crystals (f. 6, p. 763), also in slender greenish prisms with hiddenite, rutile, emerald, dolomite, muscovite, etc.; at Stony Point, N. Carolina, one of the latter habit seemed to be a cruciform-twin with tw. pl. *s* (f. 10).

10.



Alex. Co., N. C., H. & W.

In *Canada*, in North Elmsley, and passing into South Burgess, in an extensive bed 10 ft. broad, 3 ft. of which are pure sea-green apatite, and outside of this mixed with limestone, and sometimes occurring in prisms a foot long and 4 in. through, with pyroxene and phlogopite—a *fluor-apatite* containing only 0·5 chlorine (Hunt); similar in Ross; at the foot of Calumet Falls, in blue crystals; also near Blaisdell's mill on the Gatineau; at St. Roch, on the Achigan, clear rose-red, amethystine, and colorless crystals, with augite.

In extensive beds in the Laurentian gneiss of Canada, usually associated with limestone, and accompanied by pyroxene, amphibole, titanite, zircon, garnet, vesuvianite, and many other species. Prominent mines are in Ottawa county, Quebec, along the Lièvre river in the townships of Buckingham, Templeton, Portland, Hull, and Wakefield. Also in Renfrew county, Ontario, and in Lanark, Leeds, and Frontenac counties. The yield in 1889 was 30,500 tons. The crystals of apatite are sometimes of enormous size, one crystal from Buckingham, Ottawa Co., Quebec, weighed 550 lbs. and measured 72½ inches in circumference.

Apatite was named by Werner from ἀπατάειν, *to deceive*, older mineralogists having referred it to aquamarine, chrysolite, amethyst, fluor, schorl, etc.

For a comprehensive review of the occurrence of apatite, phosphorite, and calcium phosphate in general, see R. A. Penrose, U. S. G. Surv., Bull. **49**, 1888, who also gives an extended bibliography. On the Canadian deposits, see Harrington, G. Surv. Canada, 1–50 G, 1877–78; Vennor, Rep. G. Surv. Canada, 1870 *et seq.*; also Hoffmann, l. c., ref. on p. 765. On the apatite of Norway, see Brögger & Reusch, Zs. G. Ges., **27**, 646, 1875; Nyt Mag., **25**, 255, 1880; H. Sjögren, G. För. Förh., **6**, 447, 1883; G. Löfstrand, ibid., **12**, 145, 207, 1890; G. Torell, ibid., p. 365. On the phosphorite of various localities, see ref. on p. 765. See also Phosphatic Nodules below.

**Alt.**—See osteolite, etc., below. Moore and Zepharovich have described apatite altered to tallaite from Fresno Co., California. Zs. Kr., **10**, 240, 1885.

**Artif.**—Early obtained by Deville & Caron (C. R., **47**, 985, 1858, and Ann. Ch. Phys., **67**, 443, 1863). Lechartier has shown (C. R., **65**, 172, 1867) that an arsenic apatite may be made by fusion together of calcium arsenate and calcium chloride; and that from the same at a lower temperature an arsenical wagnerite is obtained in crystals. See also Fouqué-Lévy, Synth. Min., 262, 1882, Bourgeois, Reprod. Min., 178, 1884.

**Ref.**—[1] Ekaterinburg, Min. Russl., **2**, 39, 1854; see also ib., **5**, 86, 1866, where the rather widely varying angles for different localities are compared. A review of the angles for apatite from different localities is given by Baumhauer, Zs. Kr., **18**, 31, 1890, in part quoted on p. 764.

OSTEOLITE is a massive impure form of calcium phosphate, and according to A. H. Church (Ch. News, **16**, 150, 1867), after analyses of specimens from various localities, it is to be regarded as an altered apatite. The ordinary compact variety looks like lithographic stone of white to gray color. It also occurs earthy. H. = 1–2; G. = 2·8–3·1, fr. Ostheim near Hanau, Bromeis; 2·86, ibid., Church; luster feeble or wanting. Excepting impurities, it has the composition of apatite, although most analyses, excepting those of Church, do not show fluorine or chlorine. Analyses: 5th Ed., p. 533, 534. Named from ὀστέον, *bone*, and λίθος, since bones consist largely of the same phosphate.

EPIPHOSPHORITE *Breithaupt*, B. H. Ztg. **25**, 194, 1866. Occurs reniform, of scaly-granular structure, inclining to fibrous, vitreous luster, leek- to celandine-green color, with H. = 4·5–5, G. = 3·125. According to Richter it fuses with much difficulty, and affords indications of phosphoric acid, lime, iron protoxide, alumina, and a very little silica; not tested for fluorine or chlorine, because of too little material. Occurs with garnets and graphite in a crystalline rock, but locality unknown.

TALC-APATITE *Hermann*, J. pr. Ch., **31**, 101, 1844. An apatite from chlorite slate near Zlatoust, containing a large percentage of magnesia in place of part of the lime, and low in specific gravity. It occurs in 6-sided prisms, grouped or single; H. = 5; G. = 2·7–2·75; luster dull to earthy; color milk-white, yellowish externally; feebly translucent. Anal., Hermann, deducting 9·50 insoluble material as impurities:

$P_2O_5$ 43·11  CaO 41·44  MgO 8·55  $Fe_2O_3$ 1·10  Cl 0·92  $SO_3$ 2·32 F *undet.*

Berzelius suggests that the magnesia may have come from the gangue. According to Volger it is an altered impure apatite. Some magnesia is present in many apatites (Bischof).

HYDROAPATITE *Damour*, Ann. Mines, **10**, 65, 1856. In mammillary concretions, looking a little like chalcedony. H. = 5·5. G. = 3·10. Color milk-white. Subtransparent. Composition that of a *hydrous apatite*. Analysis by Damour:

$P_2O_5$ 40·00  CaO 47·31  F 3·36  Ca 3·60  $H_2O$ 5·30 = 99·57

Heated in a tube it decrepitates and gives out ammoniacal water. Found near St. Girons in the Pyrenees, in the fissures of a brownish, ferruginous, argillaceous schist, a rock which not far distant affords wavellite.

Besides the definite *mineral phosphates*, including normal apatite, phosphorite, etc., there are also extensive deposits of amorphous phosphates, consisting largely of "bone phosphate" ($Ca_3P_2O_8$), of great economic importance, though not having a definite chemical composition and hence not strictly belonging to pure mineralogy. Here belong the phosphatic nodules, coprolites, bone beds, guano, etc.

PHOSPHATIC NODULES. COPROLITES. Phosphatic nodules occur in many fossiliferous rocks of different ages, and are probably in all cases of organic origin. They sometimes present a spiral or other interior structure, derived from the animal organization that afforded them, and in such cases their coprolitic origin is unquestionable. In other cases there is no definite or only a concretionary structure. Phosphatic nodules, from the Lower Silurian rocks of Canada, contain sometimes fragments of shells of Lingula and Orbicula, which shells, unlike most others, consist largely of phosphates. They are found in the Chazy formation at Allumette Id., Hawkesbury. R. Ouelle, and elsewhere. They have been investigated by T. S. Hunt (Logan's Rep. Can., 1851–52, 1863, and Am. J. Sc., **17**, 235, 1854).

The nodular phosphatic deposits are most abundantly developed in the Tertiary of South Carolina, where they have been extensively mined since 1868. There are three principal regions: first, near Charleston, north and east of the city, from Wando river and the east branch of the Cooper river on the northeast to Rantowles creek and Stone river on the southwest. Again, west of the above from the Edisto river to Horseshoe creek, and finally between Bull and Broad rivers with the deposits of Coosaw and Beaufort rivers and those of Chisholm island. There are also other points where the nodules have been obtained. They are, in general, most abundant in river bottoms, where they have been washed together from their original beds.

The nodules are irregular in form and range from the size of a pea or larger up to a ton; the larger masses often formed by the union of many small nodules. They vary in hardness from 2 to 4 and in specific gravity from 2·2 to 2·5. They have no crystalline structure, but sometimes are distinctly concretionary. In color they vary from light gray to brown and rarely jet black. Chemically they usually consist of from 50 to 60 p. c. or more of bone phosphate, with 6 to 8 p. c. calcium carbonate, 4 to 5 p. c. organic matter and moisture, and a variable amount of sand. The nodules are accompanied by the remains of marine life of various forms, sharks' teeth, etc.

Phosphatic deposits also occur in North Carolina, Alabama, and Florida. Those of Florida have come into prominence recently (since 1889), and have already assumed considerable economic importance. The beds have been traced from near Tallahassee and Gainesville through Madison and Alachua counties, along a line nearly 250 miles long, running a little east of south to the mouth of Peace R. into Charlotte Harbor. The beds are chiefly in Madison, Alachua, Levy, Marion, Citrus, Hernando, Pasco, Hillsboro, Polk, and De Soto counties. The main point of interest is at Dunnellon between Marion and Citrus Cos. The Florida phosphate has been called *Floridite* by Cox (Proc. Amer. Assoc., p. 260, 1890). Much of it is a hard phosphate rock (*rock phosphate*), sometime a "pea-like phosphorite"; there is also a conglomerate, and again it is soft and plastic; it is stated to average about 80 p. c. or more of bone phosphate.

Other phosphate deposits occur in the greensand of England, in N. Wales (L. Silurian), in Belgium, France, Russia, etc. See further C. U. Shepard, South Carolina Phosphates (Charleston, 1880); Penrose, U. S. G. Surv., Bull. **46**, 1888, referred to above and here quoted from; also on the Florida deposits, Cox, l. c., Darton, Am. J. Sc., **41**, 102, 1891; also, in general, the authors quoted above (p. 768).

GUANO. Guano is bone phosphate of lime, mixed with the hydrous phosphates, and generally with some calcium carbonate, and often a little magnesia, alumina, iron, silica, gypsum, and other impurities. It often contains 9 or 10 p. c. of water. It is often granular or oolitic; also compact through consolidation produced by infiltrating waters, in which case it is frequently lamellar in structure, and also occasionally stalagmitic and stalactitic. Its colors are usually grayish white, yellowish and dark brown, and sometimes reddish, and the luster of a surface of fracture earthy to resinous. Shepard's *Pyroclasite* (Am. J. Sc., **22**, 97, 1856) is nothing but the hard guano from Monk's island, Caribbean sea, the mass of which he named *Pyroguanite*, under the wrong idea of its having undergone the action of heat; in a later notice (ibid.. **23**, 404. 1882) Shepard suggests that pyroclasite may be a "uniform compound of monetite and monite" or "a mechanical mixture of the two." Phipson's *Sombrerite* (J. Ch. Soc., **15**, 277, 1862) is similar to pyroclasite from Sombrero, as shown by A. A. Julien (Am. J. Sc., **36**, 423, 1863). The waters which have filtrated through the guano at Sombrero have altered the coral rock adjoining, turning it more or less completely into phosphate of lime of a yellowish or brownish color; and phosphatic stalagmites and stalactites resinous in fracture are common.

Shepard's massive *Glaubapatite*, yellowish brown to chocolate-brown in color, and in fibrous stalactites, from Monk's island (l. c.), is also in all probability merely the guano rock above described. He says the mineral contains 15·1 p. c. of sodium sulphate, with 74·0 of calcium phosphate, and 10·3 of water; but such a compound is hardly a possibility, and the fact of its existence needs confirmation. The name, from glauber and apatite, alludes to the composition The mineral includes also "tabular crystals," which may possibly be *brushite*, although the composition is against it. For analyses of the guano of Mexillones see Domeyko, C. R., **90**, 544, 1880.

For various guano minerals see monetite, struvite, brushite, metabrushite, martinite, etc., p. 784, etc.; also stercorite, p. 826

**550. PYROMORPHITE.** Grön Blyspat, Minera plumbi viridis pt., *Wall.*, Min., 296, 1748. Mine de Plomb verte *Fr. Trl.* Wall., **1**, 536, 1853. Canton Mine, 1856, Min., 407, 1857, Am. J. Sc., **24**, 38, 1857.

Hexagonal, with pyramidal hemihedrism[1]. Axis $\dot{c} = 0{\cdot}7362$; $0001 \wedge 10\bar{1}1 =$ *40° 22′ Haidinger[2].

**Forms**[3]: *c* (0001, *O*); *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2); *x* ($10\bar{1}1$, 1), *y* ($20\bar{2}1$, 2), *π* ($40\bar{4}1$, 4); *s* ($11\bar{2}1$, 2-2).

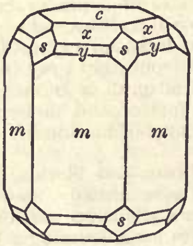
Angles: *cx* = 40° 22′, *cy* = 59° 32′, *cπ* = 73° 37′, *cs* = 55° 49′, *xx′* = 37° 47½′, *yy′* = 51° 3½′, *ππ′* = 57° 20′, *ss′* = 48° 52′, *xs* = 26° 52′, *ax* = 55° 53′.

Crystals prismatic, with faces *m* striated vertically, and often in rounded barrel-shaped forms; also in branching groups of prismatic crystals in nearly parallel position, tapering down to a slender point. Often globular, reniform, and botryoidal or verruciform, with usually a subcolumnar structure; also fibrous, and granular.

Cleavage: *m*, *x* (1011) in traces. Fracture subconchoidal, uneven. Brittle. H. = 3·5–4. G. $\doteq$ 6·5–7·1 mostly, when pure; 5·9–6·5, when containing lime. Luster resinous. Color green, yellow, and brown, of different shades; sometimes wax-yellow and fine orange-yellow; also grayish white to milk-white. Streak white, sometimes yellowish. Subtransparent to subtranslucent. Optically —. Sometimes biaxial, and increasingly so as the amount of arsenic increases. Cf. mimetite, p. 772.

1.

2.



Nerchinsk, Erem.

**Var.**—1. *Ordinary.* (*a*) *In crystals* as described; sometimes yellow and in rounded forms resembling campylite (*pseudo-campylite*). (*b*) In *acicular* and *moss-like* aggregations. (*c*) *Concretionary* groups or masses of crystals, having the surface angular. (*d*) *Fibrous.* (*e*) *Granular massive.* (*f*) *Earthy;* incrusting.

2. *Polysphærite.* Containing lime; color brown of different shades, yellowish gray, pale yellow to nearly white; streak white; G. = 5·89–6·44. Rarely in separate crystals; usually in groups, globular, mammillary, verruciform. *Miesite*, from Mies in Bohemia, is a brown variety. *Nussierite* is similar and impure, from Nussière, near Beaujeu, France; color yellow, greenish, or grayish; G. = 5·042. *Cherokine* is milk-white or pinkish white in color, and occurs in slightly acuminated prisms, and also botryoidal and massive; G. = 4·8 (?); from the Canton mine, Cherokee Co., Georgia. 3. *Chromiferous;* color brilliant red and orange. 4. *Arseniferous;* color green to white; G. = 5·5–6·6. 5. *Pseudomorphous;* (*a*) after galena; (*b*) cerussite.

Both the green and brown colors occur with the pure phosphate of lead, as well as that containing calcium.

**Comp.**—$(PbCl)Pb_4P_3O_{12}$ or also written $3Pb_3P_2O_8.PbCl_2$ = Phosphorus pentoxide 15·7, lead protoxide 82·2, chlorine 2·6 = 100·5, or Lead phosphate 89·7, lead chloride 10·3 = 100.

The phosphorus is often replaced by arsenic, and as the amount increases the species passes into mimetite. Calcium also replaces the lead to a considerable extent.

A calcium vanado-pyromorphite, with G. = 6·9–7·0, from Leadhills gave Collie: Lead phosphate 52·0, lead vanadate 19·2, calcium phosphate 15·8, lead chloride 11·4. J. Ch. Soc., **55**, 94, 1889.

**Pyr., etc.**—In the closed tube gives a white sublimate of lead chloride. B.B. in the forceps fuses easily (F. = 1·5), coloring the flame bluish green; on charcoal fuses without reduction to a globule, which on cooling assumes a crystalline polyhedral form, while the coal is coated white from chloride and, nearer the assay, yellow from lead oxide. With soda on charcoal yields metallic lead; some varieties contain arsenic, and give the odor of garlic in R.F. on charcoal. With salt of phosphorus, previously saturated with copper oxide, gives an azure-blue color to the flame when treated in O.F. (chlorine). Soluble in nitric acid.

**Obs.**—Pyromorphite occurs principally in veins, and accompanies other ores of lead.

Occurs at Poullaouen and Huelgoet in Brittany; at Zschopau and other places in Saxony; at Přibram, Mies, and Bleistadt, in Bohemia; at Sonnenwirbel near Freiberg; Clausthal in the Harz; in fine crystals at Ems, Braubach, in Nassau; also at Dernbach near Montabaur in Nassau; Kranzberg near Usingen; Berezov in Siberia; in the Nerchinsk mining district, in fine crystals; Cornwall, green and brown; Devon, gray; Derbyshire, green and yellow; Cumberland, golden yellow, in England; Leadhills, red and orange, in Scotland; Wicklow, clove-brown and yellowish green, and elsewhere, Ireland.

Pyromorphite has been found in good specimens at the Perkiomen lead mine near Philadelphia, and very fine at Phenixville; also in Maine, at Lubec and Lenox; in New York, a mile south of Sing Sing; sparingly at Southampton, Massachusetts, and Bristol, Conn.; in good crystallizations of bright green and gray colors in Davidson Co., N. C., also in Cabarrus and Caldwell Cos.

Named from *πῦρ*, *fire*, *μορφή*, *form*, alluding to the crystalline form the globule assumes on cooling. This species passes into mimetite.

**Alt.**—Occurs altered to galena, cerussite, calamine, calcite, and limonite.

Pseudoapatite (p. 764) is according to Frenzel a pseudomorph after pyromorphite.

**Artif.**—See mimetite.

**Ref.**—[1] Baumh., as shown by etching-figures, Jb. Min., 411, 1876. [2] Haid., Breisgau, Min. Mohs, **2**, 134, 1825; Rose obtained $xx' = 37° 53'$, Pogg., **9**, 209, 1827. Plomb arseniaté *Fr.* Pyromorphite pt. *Mohs.* Mimetèse *Beud.*, Tr., **2**, 594, 1832; Mimetene *Shep.*, Min., 1835; Mimetesit *Breith.*, Handb., 289, 1841; Mimetit *Haid.*, Handb., 1845, *Glocker*, Syn., 1847. Kampylit *Breith.*, Handb., **2**, 291, 1841.

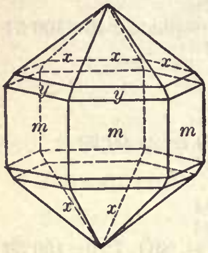
Hexagonal, with pyramidal hemihedrism[1]. Axis $\dot{c} = 0·7224$; $0001 \wedge 10\bar{1}1 = {}^{*}39° 50'$ Haidinger.[2] Observed forms as in pyromorphite. Also [3]:

$h$ ($21\bar{3}0$, $i\frac{3}{2}$), $\mu$ ($21\bar{3}1$, $3\text{-}\frac{3}{2}$). Angles: $xx' = 37° 21\frac{1}{2}'$, $cs = 55° 19'$, $ss' = 48° 33'$.

Habit of crystals like pyromorphite; sometimes rounded to globular forms. Also in mammillary crusts.

Cleavage: *x* imperfect. Fracture uneven. Brittle. H. = 3·5. G. = 7·0–7·25. Luster resinous. Color pale yellow, passing into brown; orange-yellow; white or colorless. Streak white or nearly so. Subtransparent to translucent.



Optically often biaxial. Bertrand[4] has shown that while the phosphate, pyromorphite, is normally uniaxial, the arsenate, mimetite, is biaxial and sometimes with an angle (2E) of 64°, Johanngeorgenstadt. A basal section shows a division into six triangular sectors with ax. pl. parallel to the sides of the hexagon and $Bx_a$ (–) ⊥ *c*. Jannettaz and Michel have extended these observations with analyses and shown the increase in biaxial character with increase of arsenic in passing from pure pyromorphite through its arsenical varieties to pure mimetite.

**Var.**—1. *Ordinary.* (*a*) *In crystals*, usually in rounded aggregates. (*b*) *Capillary* or filamentous, especially marked in a variety from St. Prix-sous-Beuvray, France; somewhat like asbestus, and straw-yellow in color. (*c*) *Concretionary.*

2. *Calciferous.* Here belongs a variety from Villevieille near Pontgibaud, Puy-de-Dôme. Hedyphane (p. 775) formerly was placed here, but seems to be distinct optically.

3. *Containing much phosphoric acid. Campylite*, from Drygill in Cumberland, has G. = 7·218, and is in barrel-shaped crystals (whence the name, from *καμπυλος, curved*), yellowish to brown and brownish red.

**Comp.**—$(PbCl)Pb_4As_3O_{12}$, also written $3Pb_3As_2O_8.PbCl_2$ = Arsenic pentoxide 23·2, lead protoxide 74·9, chlorine 2·4 = 100·5, or Lead arsenate 90·7, lead chloride 9·3 = 100. Phosphorus replaces the arsenic in part, and calcium the lead. *Endlichite* (p. 774) is intermediate between mimetite and vanadinite.

**Pyr., etc.**—In the closed tube like pyromorphite. B.B. fuses at 1, and on charcoal gives in R.F. an arsenical odor, and is easily reduced to metallic lead, coating the coal at first with lead chloride, and later with arsenic trioxide and lead oxide. Gives the chlorine reaction as under pyromorphite. Soluble in nitric acid.

**Obs.**—Occurs at Wheal Unity, near Redruth in Cornwall, and at several other of the Cornish mines; also at Beer Alston in Devonshire; Roughten Gill, Drygill, etc., in Cumberland; formerly at Leadhills and Wanlockhead in Scotland. At St. Prix in the Department of the Saone, in France, in capillary crystals; at Villevieille, near Pontgibaud, Puy-de Dôme; at Johanngeorgenstadt, in fine yellow crystals; at Nerchinsk, Siberia, in reniform masses, brownish red, also in fine crystals, also at Zinnwald, and Badenweiler; Långban, Sweden; Mine grande, Marqueza, Chili; Peru. At the Brookdale mine, Phenixville, Pa., crystals of pyromorphite capped with mimetite; at the Cerro Gordo mines, California.

Pseudomorphs (anal. 8) in reticulated crystalline groups, perhaps after anglesite, have been described by Genth and Rath from the Mina del Diablo, Durango, Mexico. Am. Phil. Soc., **24**, 33, 1887.

Named from *μιμητής, imitator*, it closely resembling pyromorphite. Beudant's word *mimetese* is inadmissible, because wrongly formed. Shepard's modification of it, *mimetene*, he has rejected for *mimetite* in his last edition. *Mimetite* is the correct form in view of the derivation. Mohs united this species with pyromorphite.

**Artif.**—Formed by fusing together arsenate and chloride of lead, and dissolving out afterward the excess of chloride, Lechartier, C. R., **65** 172, 1867. Michel has described the formation of crystals varying like the natural mineral from the phosphate to the arsenate and showing like optical characters. Bull. Soc. Min., **10**, 133, 1887.

**Ref.**—[1] Baumhauer, as shown by etching-figures, Jb. Min., 411, 1876. [2] Johanngeorgenstadt, Haid., Min. Mohs, **2**, 135, 1825; Schabus gives same. Eremeyev gives $\dot{c}$ = 0·7242, 0·7251, 0·7285, 0·7315 for four varieties from the Nerchinsk mining district, Vh. Min. Ges., **22**, 179 *et séq.*, 1886, and Zs. Kr., **13**, 191, 1888 (full abstract). [3] Mlr. (quoting Haid., l. c., who does not separate pyromorphite and mimetite) gives the same list as for pyromorphite, p. 481. Erem. (ref. above) adds $h$, $\mu$. [4] Btd., Bull. Soc. Figs. 1, 3, Pinal Co., Arizona, Pfd. 2, *Endlichite*, Lake Valley, Sierra Co., N. M., Id. 4, Córdoba, Websky. 5, Yuma Co., Arizona. 6, Basal projection of 3.

Crystals prismatic, with smooth faces and sharp edges; sometimes cavernous, the crystals hollow prisms; also in rounded forms and in parallel groupings like pyromorphite. In implanted globules or incrustations.

Fracture uneven, or flat conchoidal. Brittle. H. = 2·75–3. G. = 6·66–7·23; 6·886 Carinthia, Rg.; 6·863 Berezov, Struve. Luster of surface of fracture resinous. Color deep ruby-red, light brownish yellow, straw-yellow, reddish brown. Streak white or yellowish. Subtranslucent to opaque.

**Comp.**—$(PbCl)Pb_4V_3O_{12}$, also written $3Pb_3V_2O_8.PbCl_2$ = Vanadium pentoxide 19·4, lead protoxide 78·7, chlorine 2·5 = 100·6, or Lead vanadate 90·2, lead chloride 9·8 = 100.

Phosphorus is sparingly present, also sometimes arsenic, both replacing vanadium. In *endlichite* the ratio of V : As = 1 : 1 nearly. A pyromorphite, from Leadhills, carrying a large amount of vanadium is mentioned on p. 771.

**Anal.**—1, Flight, J. Ch. Soc., **25**, 1053, 1872. 2, Frenzel, Min. Mitth., 3, 504, 1880 (Jb. Min., 673, 1875). 3, Genth, Am. Phil. Soc., Oct. 2, 1885. 4, 5, Rg., Ber. Ak. **Pyr., etc.**—In the closed tube decrepitates and yields a faint white sublimate. B.B. fuses easily, and on charcoal to a black lustrous mass, which in R. F. yields metallic lead and a coating of lead chloride; after completely oxidizing the lead in O.F. the black residue gives with salt of phosphorus an emerald-green bead in R.F., which becomes light yellow in O.F. Gives the chlorine reaction with the copper test. Fused with 3 parts of potassium bisulphate forms a clear yellow mass, which on cooling reddens, becoming finally of a pomegranate-yellow color. Decomposed by hydrochloric acid.

If nitric acid be dropped on the crystals they become first deep red from the separation of vanadic oxide, and then yellow upon its solution.

**Obs.**—This mineral was first discovered at Zimapan in Mexico, by Del Rio. Later obtained among some of the old workings at Wanlockhead in Dumfriesshire, where it occurs in small globular masses, on calamine, and also in small hexagonal crystals; also at Berezov in the Ural, with pyromorphite; and near Kappel in Carinthia, in crystals; at Undenäs, Bölet, Sweden. In the Sierra de Córdoba, Argentine Republic. South Africa (anal. 1).

In the U. States, sparingly with wulfenite and pyromorphite as a coating on limestone near Sing Sing, N. Y. Abundant in the mining regions of Arizona and New Mexico, often associated with wulfenite and descloizite. In Arizona, at the Hamburg, Melissa, and other mines in Yuma Co., in brilliant deep red crystals; Vulture, Phœnix, and other mines in Maricopa Co.; at the Black Prince mine, also from the Mammoth gold mine, near Oracle, Pinal Co.; in brown barrel-shaped crystals in the Humbug dist., Yavapai Co. In New Mexico, at Lake Valley, Sierra Co. (*endlichite*); and the Mimbres mines near Georgetown. Sparingly in Montana at the Bald Mountain mine, Beaver Co. Endlichite is named after Dr. F. M. Endlich.

Before it was shown by Roscoe that the vanadium oxide was $V_2O_5$ instead of $VO_3$ it was supposed that vanadinite crystals might be pseudomorphs after pyromorphite.

Del Rio discovered this species at Zimapan, and obtained from it, in 1801, 80·72 of lead oxide, and 14·8 of a new metallic acid, the basis of which he called *Erythronium*. This result was later (1804) set aside by himself, and also by Descotils, both of whom made the acid the chromic, and the mineral a *brown* chromate of lead. The metal vanadium was not discovered by Sefstrom until 1830, and then in iron made of ore from Taberg, Sweden; and in the same year Wöhler showed that Del Rio's lead ore was a vanadate.

**Ref.**—[1] From Kappel, Carinthia, Zs. Kr., 4, 353, 1880. [a] Pb 49·20, $PbCl_2$ 11·76.

From Långban, Sweden; also from Pajsberg, but containing no barium. Named ἡδυφανης, *of attractive aspect.*

Hedyphane has ordinarily been included as a calcium variety of mimetite to which it seems to correspond in composition, but if monoclinic, as suggested by Dx. (Bull. Soc. Min., **4**, 93, 1881), it must stand independently. It needs further investigation.

**Pleonectite.** Pleonektit *L. J. Igelström*, G. För. Förh., **11**, 210, 1889, Jb. Min., **2**, 40, 1889.

Occurs in embedded grains with arseniopleite and an undetermined antimonio-arsenate of manganese in a gangue of hausmannite, rhodonite, calcite at the Sjö mine, Grythytte parish, Örebro, Sweden. Massive with indistinct cleavage. H. = 4. Luster resinous. Color grayish white. Translucent in thin splinters. Contains $As_2O_5$, $Sb_2O_5$, PbO, Cl, but not analyzed.

Named from πλεονεκτεῖν, *to have more,* in allusion to the fact that several related minerals occur at the same mine.

## 4. Wagnerite Group. Monoclinic.

Phosphates of magnesium (calcium), iron and manganese containing fluorine (also hydroxyl). Formula $R_2FPO_4$ or $(RF)RPO_4$.

[a] $Fe_2O_3$ and $Al_2O_3$.

From 1, 2·68 p. c. $SiO_2$ has been deducted.

**Pyr., etc.**—B.B. in the forceps fuses at 4 to a greenish gray glass; moistened with sulphuric acid colors the flame bluish green. With borax reacts for iron. On fusion with soda effervesces, but is not completely dissolved; gives a faint manganese reaction. Fused with salt of phosphorus in an open glass tube reacts for fluorine. Soluble in nitric and hydrochloric acids. With sulphuric acid evolves fumes of hydrofluoric acid.

**Obs.**—*Wagnerite* occurs in the valley of Höllengraben, near Werfen, in Salzburg, Austria, in irregular veins of quartz, traversing clay slate. Named after the Oberbergrath Wagner. *Kjerulfine* is from Kjörrestad, near Bamle, Norway. Named after Prof. Th. Kjerulf of Christiania (1828–1888).

**Artif.**—Obtained by Deville & Caron (C. R., **47**, 985, 1858, Ann. Ch. Phys., **67**, 454, 1863) by fusing ammonium phosphate with magnesium fluoride and an excess of magnesium chloride. Other isomorphous compounds were formed with chlorine in place of fluorine, also iron, manganese, corresponding to triplite, etc. Lechartier (C. R., **65**, 172, 1867) has obtained an arsenical wagnerite.

**Ref.**—[1] Min., p. 489, the predominating prism (*g* of Mlr.) here, as in kjerulfine (and triploidite), is made the unit prism. [2] See Mlr., l. c. [3] Bgr. on Kjerulfine, Zs. Kr., **3**, 474, 1879.

CRYPHIOLITE. Crifiolite *A. Scacchi,* Acc. Sc. Napoli, 1, No. 5, 1886 (read Sept. 8, 1883). Kryphiolith.

In small monoclinic crystals, tabular ‖ *a* and showing the forms:

*a* (100, *i-ī*), *c* (001, *O*), *e* ($\bar{2}01$, 2-*ī*), *μ* (111, − 1), *n* ($\bar{1}11$, 1). Approximate measured angles: $ac = 65° 52'$, $ce = 78° 46'$, $c\mu = 51° 42'$, $cn = 69° 1'$, $a\mu = 54° 39'$, $\mu\mu' = 88° 44'$, $nn' = 112° 36'$, $\mu n = 49° 17'$.

H. about 6. Brittle. G. = 2·674. Luster vitreous. Color honey-yellow. Transparent.

Composition uncertain, but apparently not far from wagnerite. Anal.—Scacchi, on 0·07 gram (analysis corrected by Cathrein, Zs. Kr., **14**, 525, 1888):

| $P_2O_5$ | MgO | CaO |
|---|---|---|
| 47·59 | 33·72 | 14·74 |

Regarding the loss as fluorine, the amount is found to be 6·93 p. c. B.B. becomes opaque, without complete fusion.

Found at Vesuvius in a mass of a conglomerate, consisting of fragments of leucitophyre and volcanic sand, enveloped in the lava of 1872. The crystals are concealed by a coating of apatite, hence the name from *κρύφιος, concealed.*

**554. SPODIOSITE.** *H. V. Tiberg*, G. För. Förh., **1**, 84, 1872.

Orthorhombic? In flattened (‖ *b*) prismatic crystals with the forms:

*b* (010, *i-ĭ*), *m* (110, *I*), *e* (021, 2-*ĭ*), *p* (111, 1). Angles: $mm''' = 84°$, $ee' = 147°$.

Cleavage: *b* distinct; *c* indistinct. Fracture uneven. Brittle. H. = 5. G. = 2·94. Luster dull porcelain-like, but vitreous. Color ash-gray, inclining to brown. Streak white.

**Comp.**—A calcium fluo-phosphate, perhaps $(CaF)CaPO_4$ or $Ca_3P_2O_8.CaF_2$, analogous to wagnerite (A. Sjögren).

**Anal.**—C. H. Lundström, l. c.

| $P_2O_5$ | CaO | MgO | F | $As_2O_5$ | $CO_2$ | Cl | $Fe_2O_3$ | $Al_2O_3$ | MnO | $H_2O$ | insol. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 32·20 | 49·81 | 2·27 | [4·71][a] | 0·24 | 3·90 | 0·12 | 1·24 | 1·11 | 0·55 | 2·70 | 1·15 = 100 |

[a] Including loss [but the analysis should show an excess].

**Pyr.**—B.B. fuses in the thinnest splinters to a white enamel; does not decrepitate. Soluble in hydrochloric and nitric acids with effervescence.

**Obs.**—From the Krangrufva, Wermland, Sweden. Named from *σπόδιος, ash-gray.*

A relation to wagnerite which has $MM''' = 84° 36'$, is suggested by A. Sjögren, (ibid., **7**, 666, 1885), which suggestion is here provisionally accepted.

**555. TRIPLITE.** Phosphate natif de fer melangé de manganèse (fr. Limoges) *Vauq.*, J. de M., **11**, 295, 1802, Ann. Ch., **41**, 242, 1802. Eisenpecherz pt. *Wern.*, 1808. Manganèse phosphaté *Lucas*, Tabl., **1**, 169, 1806. Phosphormangan *Karst.*, Tabl., 72, 1808. Manganèse phosphaté ferrifère, *H.*, Tabl., 1809. Triplit *Hausm.*, Handb., 1079, 1813. Igelström*, Öfv. Ak. Stockh., **39**, No. 2, 86, 1882.

Monoclinic Dx.[1] Massive, imperfectly crystalline.

Cleavage: unequal in two directions perpendicular to each other, one much the more distinct. Fracture small conchoidal. H. = 4–5·5. G. = 3·44–3·8; 3·617 Peilau, Berg. Luster resinous, inclining to adamantine. Color brown or blackish brown to almost black. Streak yellowish gray or brown. Subtranslucent to opaque. Somewhat pleochroic.

Optically +. Ax. pl. nearly ‖ to the difficult, and ⊥ to the easy cleavage; to the latter $Bx_a$ is inclined 42° 10′ red, and 41° 53′ yellow. Dispersion $\rho > v$. Axial angles, Dx.[1]:

$$2H_{a.r} = 96° 15' \qquad 2H_{a.y} = 95° 27' \qquad 2H_{a.gr} = 95° 20' \qquad 2H_o = 125° 30'$$

**Comp., Var.**—$(RF)RPO_4$ or $R_3P_2O_8.RF_2$ with R = Fe and Mn, also Ca and Mg. The ratio varies widely, in anal. 1, Fe : Mn = 1 : 1; in 2 (zwieselite), Fe : Mn = 2 : 1; in 3, 1 : 2; in 5, 1 : 7.

*Talktriplite* is a variety from Horrsjöberg, containing magnesium and calcium in large amount; it occurs in embedded grains of a yellow or yellowish red color.

**Anal.**—1. Kbl., J. pr. Ch., **92**, 390, 1864. 2, Rg., Min. Ch., 351, 1860. 3, 4, Siewert, light and dark colored, Min. Mitth., 225, 1873. 5, Penfield, priv. contr. 6, Igelström, l. c.

| 6. | *Talktriplite* | 32·82 | 16·12 | 14·86 | 14·91 | 17·42 | *undet.* | = 96·13 |

Earlier analysts, Berzelius, Bergemann, overlooked the fluorine. See 5th Ed., p. 543.

**Pyr., etc.**—B.B. fuses easily at 1·5 to a black magnetic globule; moistened with sulphuric acid colors the flame bluish green. With borax in O.F. gives an amethystine colored glass (manganese); in R.F. a strong reaction for iron. With soda reacts for manganese. With sulphuric acid evolves hydrofluoric acid. Soluble in hydrochloric acid.

**Obs.**—Found by Alluaud at Limoges in France, in a vein of quartz in granite, accompanied by apatite; occurs also at Peilau in Silesia; from Helsingfors, Finland; also from Sierra de Córdoba, Argentine Republic, in masses in quartz with beryl, apatite, columbite; it is in part altered to a mineral like heterosite. Also found at Stoneham, Maine; at Branchville, Conn.

*Zwieselite*, a clove-brown variety, is from Rabenstein, near Zwiesel, in Bavaria, in quartz (G. = 3·97 Fuchs). *Talktriplite* occurs in a rock carrying lazulite at Horrsjöberg, Wermland, Sweden.

**Alt.**—Often occurs coated with manganese oxide as a result of its alteration, and is sometimes changed to a substance near heterosite, p. 757.

**Ref.**—[1] Dx., N. R., 180, 1867.

GRIPHITE *W. P. Headden*, Am. J. Sc., **41**, 415, 1891.

A problematical phosphate, occurring in embedded reniform masses. Optically amorphous. Cleavage none. Fracture uneven to conchoidal. Brittle. H. = 5·5. G. = 3·401. Luster resinous to vitreous. Color dark brown. Translucent.

Anal.—1, Headden, l.c., mean of two complete and three partial analyses. 2, L. G. Eakins, U. S. G. Surv., Bull. **60**, 135, 1890.

| | $P_2O_5$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | FeO | CaO | $Na_2O$ | $K_2O$ | $Li_2O$ | F | Cl | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 38·52 | 10·13 | — | 29·64 | 4·00 | 7·62[a] | 5·52 | 0·30 | *tr.* | *tr.* | 0·11 | 4·29 | insol. 0·16 = 100·29 |
| 2. | 39·68 | 8·74 | 2·36 | 29·13 | 1·97 | 6·72 | 5·25 | *tr.* | 0·13 | 2·35 | 0·25 | 3·67 | $CO_2$ 0·26, $SiO_2$ 0·43 = 100·94 |

[a] Incl. 0·15 MgO.

In anal. 1 the oxygen ratio for bases (including water) to acid is 1 : 1 very nearly, and Headden suggests the formula $R_6P_2O_{10}$ or a salt of normal phosphoric acid $H_5PO_5$. The fact, however, that no other similar salts are known among minerals makes the suggestion of doubtful value. Other analyses gave confirmatory results, and it is significant that Eakins obtained so nearly the same composition on independent material, but the presence of fluorine lends support to the suggestion that the mineral may have been derived from triplite.

The material analyzed by Headden was from the Riverton lode near Harney City, Pennington Co., S. Dakota; occurs in kidney shaped masses, sometimes 50 lbs. in weight, embedded in granite. Externally the masses are dark brown due to oxidation. Eakins's mineral was from a tin mine near Rapid City, S. Dakota. Named from *γρίφος, an enigma.*

A phosphate occurring in green massive forms resembling apatite, at Stoneham, Me., afforded O. H. Drake (priv. contr.):

| $P_2O_5$ | FeO | MnO | CaO | MgO | $Na_2O$ | $K_2O$ | F | |
|---|---|---|---|---|---|---|---|---|
| 40·54 | 33·39 | 11·47 | 2·53 | 0·36 | 6·16 | 1·57 | 3·70 | $Fe_2O_3$ 0·79, $Al_2O_3$ 1·38=101·89, deduct O(=2F) 1·59 = 100·30 |

It is optically biaxial (Pfd.) and may represent a new species; the analysis, however, does not yield a satisfactory formula.

SARCOPSIDE. Sarkopsid *M. Websky*, Zs. G. Ges., **20**, 245, 1868.

Monoclinic? occurring in irregular ellipsoids, sometimes in distorted six-sided plates.

H. = 4. G. = 3·692–3·730. Luster glistening to silky and greasy. Color, on fresh surface, flesh-red to lavender-blue. Translucent in thin splinters. Streak straw-yellow, some grains give a green color. Analysis, Websky:

§ $P_2O_5$ 34·73 $Fe_2O_3$ 8·83 FeO 30·53 MnO 20·57 CaO 3·40 $H_2O$ [1·94] F *und.*

Soluble in dilute hydrochloric and sulphuric acids. Occurs with vivianite and hureaulite in a granite vein on a ridge between Michelsdorf and the valley of the Mühlbach in Silesia.

Perhaps an impure, partially altered triplite.

**556. TRIPLOIDITE.** *G. J. Brush* and *E. S. Dana,* Am. J. Sc., **16**, 42, 1878.

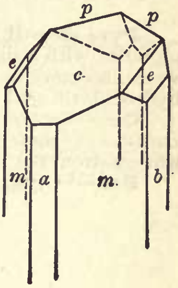
Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 1·85715 : 1 : 1·49253$; $\beta = {*}71° 46' = 001 \wedge 100$ E. S. Dana.

$100 \wedge 110 = {*}60° 27'$, $001 \wedge 101 = 31° 22\frac{5}{6}'$, $001 \wedge 011 = {*}54° 48'$.

**Forms**[1]: *a* (100, *i-ī*), *b* (010, *i-ì*), *c* (001, *O*); *m* (110, *I*); *e* (011, 1-ì); *p* ($\bar{2}$11, 2-$\bar{2}$).

Angles: *mm‴* = 120° 54′, *ee′* = 109° 36′, *cm* = 81° 7′, *cp* = 76° 35′, *pp′* = 82° 53,′ *ap* = 52° 49′, *me* = 36° 53′.

Crystals striated vertically. Commonly in crystalline aggregates, parallel-fibrous to columnar; also divergent, or confusedly fibrous to nearly compact or massive.



Cleavage: *a* perfect. Fracture subconchoidal. Brittle. H. = 4·5–5. G. = 3·697. Luster vitreous to greasy adamantine. Color yellowish to reddish brown, in isolated crystals also topaz- to wine-yellow, occasionally hyacinth-red. Streak nearly white. Transparent to translucent. Pleochroism faint. The axes of elasticity in the clinodiagonal section nearly coincide respectively with the vertical axis (3° to 4° behind) and a normal to *a*.

**Comp.**—$(Mn,Fe)P_2O_8.(Mn,Fe)OH_2$ or $4(Mn,Fe)O.P_2O_5.H_2O$. If R = Mn : Fe = 3 : 1, the percentage composition is: Phosphorus pentoxide 32·0, iron protoxide 16·2, manganese protoxide 47·8, water 4·0 = 100.

**Anal.**—1, 2, S. L. Penfield, l. c.

| | $P_2O_5$ | FeO | MnO | CaO | $H_2O$ |
|---|---|---|---|---|---|
| 1. | $\frac{2}{2}$ 32·11 | 14·88 | 48·45 | 0·33 | 4·08 = 99·85 |
| 2. | 32·24 | 18·65 | 42·96 | *und.* | 4·09 quartz 1·09 = 99·03 |

**Pyr., etc.**—In the closed tube gives off neutral water, turns black and becomes magnetic. Fuses quietly in the naked lamp-flame, and B.B. in the forceps colors the flame green. Reacts for manganese and iron with the fluxes. Soluble in acids.

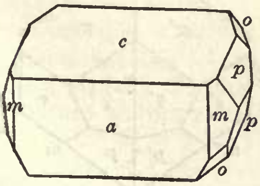
**Obs.**—Occurs at Branchville, Fairfield Co., Conn., intimately associated with eosphorite, dickinsonite, lithiophilite, and other species, in a vein of albitic granite. In crystalline form triploidite is very similar to wagnerite, and as the formulas of the latter species and of triplite are closely analogous, it is concluded that the three species are isomorphous; in triploidite, the hydroxyl (OH) takes the place of the fluorine. Named from triplite and εἶδος, *form,* in allusion to the close similarity between the two species.

Triplite also occurs at Branchville (anal. 5, p. 778), but it cannot be concluded from this fact that triploidite is only an altered triplite, which has lost its fluorine and taken up water, for the analyses of triploidite were made on perfectly clear glassy crystalline fragments.

**557. SARKINITE.** *A. Sjögren,* G. För. Förh., **7**, 724, 1885. Polyarsenite *L. J. Igelström,* Öfv. Ak. Stockh., **42**, 257, 1885, Bull. Soc. Min., **8**, 369, 1885.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 2·0017 : 1 : 1·5154$; $\beta = 62° 13\frac{1}{2}' = 001 \wedge 100$ Flink[1].

$100 \wedge 110 = 60° 33'$, $001 \wedge \bar{1}01 = 45° 59'$, $001 \wedge 011 = 53° 17'$.



*Sarkinite,* Flink.

**Forms**[1]: *a* (100, *i-ī*), *b* (010, *i-ì*), *c* (001, O); *m* (110, *I*); *p* (021, 2-ì); *o* ($\bar{1}$11, 1).

Angles: *mm‴* = 121° 6′, *mm′* = *58° 54′, *pp′* = 139° 6′, *cm* = 76° 45′, *co* = 66° 39′, *a′o* = 79° 44′, *oo′* = 110° 26′, *m′o* = *36° 36′, *mo* = *51° 8′.

Crystals somewhat elongated ‖ axis $\overset{|}{b}$ and flattened ‖ *a*. Faces *a* striated vertically or uneven, *c* uneven. Sometimes grouped in spherical forms.

Cleavage: prismatic (?) distinct. H. = 4–5. G. = 4·17–4·19. Luster greasy.

Color rose-red, flesh-red, reddish yellow. Streak light rose-red. Optically −. Double refraction strong. Ax. pl. ∥ $\bar{b}$. Bx ∧ $\acute{c} = -54°$. Ax. angle about 83°, Btd.

**Comp.**—$Mn_3As_2O_8.Mn(OH)_2$ or $4MnO.As_2O_5.H_2O$ = Arsenic pentoxide 43·3, manganese protoxide 53·3, water 3·4 = 100.

**Anal.**—1, C. H. Lundström, G. För. Förh., **7**, 725, 1885. 2, H. G. Söderbaum, Öfv. Ak. Stockh., **42**, 258, 1885. 3, A. Hamberg, G. För. Förh., **10**, 381, 1888.

| | G. | | $As_2O_5$ | $P_2O_5$ | MnO | $H_2O$ | |

[a] Regarded as too low.   [b] A second trial gave F = 7·49 p. c.

**Pyr., etc.**—In the forceps fuses at 2 giving an intense soda flame. In the closed tube blackens at a moderate temperature, but regains its color on cooling; at a higher heat fuses easily to a yellow glass and gives a faint white volatile sublimate, etching the tube slightly. The same in the open tube, with evolution of acid fumes, reddening litmus paper. On charcoal, B.B. fuses readily and gives a white sublimate with a strong arsenical odor in R.F. With soda and charcoal powder in a matrass yields a sublimate of metallic arsenic. With the fluxes reacts for iron and manganese. Decomposed by sulphuric acid with evolution of fluohydric acid.

**Obs.**—Found at the Barranca tin mine, eighteen miles northeast of Coneto, State of Durango, and about ninety miles northeast of the city of Durango, Mexico. Occurs in a vein four to six inches in thickness; the crystals are sometimes attached to the walls of the vein (here the large, light, orange-colored variety), sometimes with cassiterite in the white pulverulent matter which fills the veins (small, dark colored variety). The largest crystal found was 19 × 11 mm.

**Ref.**—[1] Ann. Ch. Phys., 4, 401, 1875.

**559. AMBLYGONITE.** Amblygonit *Breith.*, Hoffm. Min., 4, b, 159, 1817, Handb., 483. Montebrasite *Dx.*, C. R., **73**, 306, 1247, 1871. Hebronit *Kbl.*, Ber. Ak. München, 284, 1872.

Triclinic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·73337 : 1 : 0·76332$; $\alpha = 108° 51\frac{1}{4}'$, $\beta = 97° 48\frac{1}{6}'$, $\gamma = 106° 26\frac{2}{3}'$ J. D. Dana[1].

$100 \wedge 010 = 69° 35\frac{1}{2}'$, $100 \wedge 001 = *75° 30'$, $010 \wedge 001 = 67° 38'$.

**Forms**[1]: *a* (100, *i-ī*), *c* (001, *O*); *m* (110, *I'*), *M* (1$\bar{1}$0, *'I*), *z* (1$\bar{2}$0, *'i-*$\breve{2}$); *l* (101, '1-ī' L, Dx.) as tw. pl., *h* ($\bar{1}$01, ,1-ī, H, Dx.), *e* (0$\bar{2}$1, '2-ĭ).

*am* = 29° 35'   *az* = 72° 7'   *lh* = 90° 24'   *cM* = *92° 20'
*aM* = *44° 30'   *al* = 37° 10'   *ce* = *74° 40'   *eM* = *66° 30'
*mM* = 74° 5'   *ch* = 53° 14'   *cm* = 68° 9'   *ae* = 101° 25½'

Crystals large and coarse; forms rarely distinct. Usually cleavable to columnar and compact massive. Polysynthetic twinning lamellæ common, parallel to *l* and *h*, two planes nearly at right angles to each other (89° 8' Dx.), and *h* usually the more prominent, nearly bisecting the interior angle *ac* (cf. f. 2).

Cleavage: *c* perfect, with pearly luster; *a* somewhat less so, vitreous; *e* (0$\bar{2}$1) sometimes equally distinct; *M* (1$\bar{1}$0) difficult. Fracture uneven to subconchoidal. Brittle. H. = 6. G. = 3·01–3·09. Luster vitreous to greasy, on *c* pearly. Color white to pale greenish, bluish, yellowish, grayish or brownish white. Streak white. Subtransparent to translucent.

1.

Optically −. For the Penig mineral (*amblygonite*, Dx. 1872): ax. pl. inclined $12\frac{1}{2}°$ to *a*, $67\frac{1}{4}°$ to *c*, and the plane ($S$) ⊥ $Bx_a$ inclined almost equally to *a* and *c*, normal angles $Sa = 80° 52'$, $Sc = 80° 35'$, Dx. $Bx_a$ inclined 11° 40′ to edge *a*/*c*. $\beta_y = 1·594$ Na. Dispersion $\rho > v$ small. $2E_r = 86° 23'$, $2E_y = 86° 21'$.

Some varieties (*montebrasite*, Dx., 1872, see below) are also optically negative, but the ax. pl. is inclined about 23° to *c* and 82° to *a*. $Bx_a$ nearly ∥ edge *a*/*c*. Axial angles large and variable:

$$2H_{a.r} = 95° 48'–102° 38' \qquad 2H_{o.r} = 102° 50'–106° 10'$$

Refractive indices:

$$\alpha = 1·579 \qquad \beta = 1·593 \qquad \gamma = 1·597 \text{ Lévy-Lcx.}$$

**Comp.**—A fluo-phosphate of aluminium and lithium, $Li(AlF)PO_4$ or $AlPO_4.LiF$ = Phosphorus pentoxide 47·9, alumina 34·4, lithia 10·1, fluorine 12·9 = 105·3, deduct (O = 2F) 5·3 = 100. Sodium often replaces part of the lithium, and hydroxyl part of the fluorine.

Cf. Rg., Jb. Min., **1**, 15, 1883, and Min. Ch. Erg., 5, 1886, who takes a somewhat different view of the composition. He regards the water as due to gradual alteration and proposes the formula: $Al_2F_6 + 2(R_3PO_4 + Al_2P_2O_8)$ or perhaps $\begin{cases} 2LiF + Al_2F_6 \\ 2Li_3PO_4 + 3Al_2P_2O_8 \end{cases}$.

**Anal.**—1–8, Penfield, Am. J. Sc., **18**, 295, 1879.

Other analyses, Pisani, C. R., **75**, 79, 1872; Kbl., l. c.; Rg., Ber. Ch. Ges., 78, 1872, these are quoted in Min., 5th Ed., App. II, p. 271, 1875; see also 5th Ed., p. 546, where the early analyses of Berzelius and of Rammelsberg are quoted.

**Pyr., etc.**—In the closed tube yields water, which at a high heat is acid and corrodes the glass. B.B. fuses easily (at 2) with intumescence, and becomes opaque white on cooling. Colors the flame yellowish red with traces of green; the Hebron variety gives an intense lithia-red; moistened with sulphuric acid gives a bluish green to the flame. With borax and salt of phosphorus forms a transparent colorless glass. In fine powder dissolves easily in sulphuric acid, more slowly in hydrochloric acid.

**Obs.**—Occurs at Chursdorf and Arnsdorf, near Penig in Saxony, where it is associated with tourmaline and garnet in granite; near Geier, Saxony; also at Arendal, Norway. At Montebras, Creuze, France, in two varieties, cf. below.

In the U. States, in Maine, at Hebron, embedded in a coarse granite in masses, sometimes well crystallized, with lepidolite, albite, quartz, red, green, and black tourmaline, apatite, and rarely cassiterite; also at Mt. Mica in Paris, 8 m. from Hebron, with tourmaline; Auburn; at Peru, abundant with spodumene, petalite, lepidolite, etc. Occurs very sparingly at Branchville, Conn., with spodumene, also lithiophilite and other manganese phosphates in a vein of albitic granite.

The name *amblygonite* is from ἀμβλὺς, *blunt*, and γόνυ, *angle; montebrasite* and *hebronite* from the localities. The name montebrasite was first given to normal amblygonite from Montebras, made a new species on the basis of an analysis by Moissenet, later shown to be incorrect by Pisani and von Kobell (cf. App. I, p. 10, II, 27); this name was afterwards transferred (Dx., 1872) to the mineral of Hebron (= *hebronite*, Kbl.) and to another variety (B) from Montebras, translucent and greenish in color, the original Montebras mineral (A, dull white or with a violet tinge) and that from Penig being united (Dx.) under the name amblygonite; the two varieties differ in optical characters, as shown above, and perhaps also in composition; cf. analyses 1, 2, (amblygonite, Dx.), which show soda and but little water, with the other anals., which have little soda and several per cent of water.

**Ref.**—[1] On a crystal from Hebron in the Brush collection, re-examined by the author, cf. 5th Ed., p. 545. With Dx., *p* = *c*, *m* = *a*, *t* = *M*, for the angles for these three cleavages he gives (Hebron) *pm* = 75°, *pt* = 90° to 90° 45′, *mt* = 44° to 45°. On the Penig mineral and Montebras A he noted only the cleavages *a* and *c*, with *ac* = 74° 16′. C. R., **57**, 357, 1863, Ann. Ch. Phys., **27**, 385, 1872.

## B. Acid and Basic Phosphates, Arsenates, etc.

**560. Monetite** $HCaPO_4$ Triclinic
**Natrophite** $HNa_2PO_4$?

## **Olivenite Group.** Orthorhombic.

Basic phosphates, arsenates, etc., of copper, zinc, and lead.

$$R_2(OH)(P,As,V)O_4 \text{ or } (ROH)R(P,As,V)O_4 \quad R = Cu, Zn, Pb.$$

As noted by Groth this group corresponds in a measure to the monoclinic Wagnerite Group, p. 775, which also includes basic members.

**560. MONETITE.** *C. U. Shepard*, Am. J. Sc., **23**, 400, 1882.

Triclinic. In thin rhomboidal crystals with *a* (100), *b* (010), *c* (001), *m* (110), *M* ($1\bar{1}0$), the hemi-prisms *μ*, *n* ($\mathrm{h\bar{k}0}$) and *l* (hk0), dome *e* ($\bar{1}01$).

Approximate angles: *aM* = 42°, *ab′* = 81°, *aμ* = 17°, *an* = 28°, *al* = 18°, *ac* = 76°, *a′e* = 42° E. S. Dana.

Crystals small with rough faces, often arranged in interpenetrating groups. Also massive.

Cleavage: *a* distinct. Fracture uneven. Brittle. H. = 3·5. G. = 2·75. Luster vitreous. Color pale yellowish white. Semitransparent.

**Comp.**—Acid calcium phosphate, $\mathrm{HCaPO_4}$ or $\mathrm{2CaO.P_2O_5.H_2O}$ = Phosphorus pentoxide 52·2, lime 41·2, water 6·6 = 100.

**Anal.**—C. U. Shepard, Jr., l. c., after deducting 9·78 p. c. gypsum.

| | | | | |
|---|---|---|---|---|
| $\frac{2}{3}$ | $\mathrm{P_2O_5}$ 52·28 | CaO 41·14 | $\mathrm{H_2O}$ 6·58 | = 100 |

**Pyr.**—B.B. in the forceps turns white and fuses to a globule with crystalline facets; gives off water in the closed tube.

**Obs.**—Found in the Tertiary limestone of the islands Moneta and Mona, West Indies, underneath a bed of bird guano. Occurs in thick isolated masses, two or three inches across, also in irregular seams in gypsum, and in crusts lining cavities.

NATROPHITE *Pisani;* mentioned by Adam. Tabl. Min., 45, 1869. Pisani, Min., 288, 1883. Acid sodium phosphate, $\mathrm{HNa_2PO_4}$ = Phosphorus pentoxide 64·0, soda 27·9, water 8·1 = 100.

---

## **Olivenite Group.** Orthorhombic.

**561. OLIVENITE.** Arseniksaures Kupfererz (fr. Cornwall) *Klapr.*, Schrft. Ges. Nat. Fr. Berl., **7**, 160, 1786; Olivenerz (fr. Cornwall) *Wern.*, Bergm. J., 382, 385, 1789. Olive Copper Ore *Kirwan*, **2**, 151, 1796. Olive-green Copper Ore *Rashleigh*, Brit. Min., **1**, pl. 11, f. 2, 1797, **2**, pl. 6, 1802. Cuivre arseniaté en octaèdre aigus *Bourn.*, Phil. Tr., 177, 1801. Pharmakochalzit pt. *Hausm.*, Min., **3**, 1042, 1813; Olivenkupfer, id., 1045; Pharmacolzit *id.*, 1025, 1847. Olivenite pt. *Jameson*, Syst., **2**, 335, 1820; *Leonh.*, Orykt., 283, 1821.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·9396 : 1 : 0·6726 Washington[1].

100 ∧ 110 = 43° 13′, 001 ∧ 101 = 35° 35¾′, 001 ∧ 011 = 33° 55½′.

**Forms**[1]: *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\breve{i}$); *m* (110, *I*); *v* (101, 1-$\bar{i}$); *e* (011, 1-$\breve{i}$).

Angles: *mm‴* = *86° 26′, *vv′* = 71° 11½′, *ee′* = *67° 51′; *ve* = 47° 34′.

Crystals prismatic, often acicular; faces usually somewhat uneven. Also globular and reniform, indistinctly fibrous, fibers straight and divergent, rarely irregular; also curved lamellar and granular.

Cleavage: *m*, *b*, *e* (011) in traces. Fracture conchoidal to uneven. Brittle. H. = 3. G. = 4·1–4·4. Luster adamantine to vitreous; of some fibrous varieties pearly. Color various shades of olive-green, passing into leek-, siskin-, pistachio-, and blackish green; also liver- and wood-brown; sometimes straw-yellow and grayish white. Streak olive-green to brown. Subtransparent to opaque.

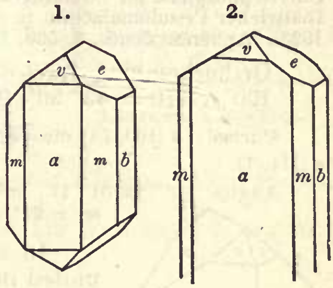

Fig. 1, Cornwall, Phillips. 2, Utah, Washington.

Optically +. Ax. pl. ∥ *c*. Bx ⊥ *a*. Dispersion $\rho < v$ large. Axial angles, Dx.[2]:

$$2H_{a.r} = 105° \ 5' \qquad 2H_{a.y} = 106° \ 6' \qquad 2H_{a.bl} = 109° \ 47'$$

**Var.**—(*a*) *Crystallized;* G. = 4·378 Cornwall, Damour; 4·135 ib., Hermann.

(*b*) *Fibrous;* finely and divergently fibrous, of green, yellow, brown, and gray, to white colors, with the surface sometimes velvety or acicular; G. = 3·913 Hermann; found investing the common variety or passing into it; called *wood-copper* or *wood-arsenate* (*Holzkupfererz*).

(*c*) *Earthy;* nodular or massive; sometimes soft enough to soil the fingers.

**Comp.**—$Cu_3As_2O_8.Cu(OH)_2$ or $4CuO.As_2O_5.H_2O$ = Arsenic pentoxide 40·7, cupric oxide 56·1, water 3·2 = 100.

**Anal.**—1, Damour, Ann. Ch. Phys., **13**, 412, 1845. 2, Hillebrand, Proc. Col. Soc., **1**, 113, 1884. Other analyses 5th Ed., p. 564.

| | | $As_2O_5$ | $P_2O_5$ | CuO | $H_2O$ |
|---|---|---|---|---|---|
| 1. Cornwall | G. = 4·378 | 34·87 | 3·43 | 56·86 | 3·72 = 98·88 |
| 2. Utah, *wood-copper* | | 40·05 | 0·06 | 55·40 | 3·39 gangue 0·81 = 99·71 |

**Pyr., etc.**—In the closed tube gives water. B.B. fuses at 2, coloring the flame bluish green, and on cooling the fused mass appears crystalline. B.B. on charcoal fuses with deflagration, gives off arsenical fumes, and yields a metallic arsenide which with soda yields a globule of copper. With the fluxes reacts for copper. Soluble in nitric acid.

**Obs.**—The crystallized varieties occur disposed on, or coating, cavities of quartz in Cornwall, at Wheal Gorland, Ting Tang, Wheal Unity, and other mines near St. Day; also near Redruth; near Tavistock, in Devonshire; also in inferior specimens at Alston Moor, in Cumberland; at Camsdorf and Saalfeld in Thuringia; Tyrol; the Banat; Nizhni Tagilsk in the Ural; Chili.

In the U. S., in Utah, at the American Eagle and Mammoth mines, Tintic district, both in crystals and the form of *wood-copper*.

The name olivenite alludes to the olive-green color.

**Ref.**—[1] Utah, Am. J. Sc., **35**, 298, 1888. Earlier measurements by Phillips, Min., 319, 1823, who gives $mm''' = 87° \ 30'$, $ee' = 69° \ 10'$, hence $\breve{a} : \bar{b} : \dot{c} = 0·9573 : 1 : 0·6894$. Cf. also **Dx.**, Ann. Ch. Phys., **13**, 417, 1845. [2] Propr. Opt., **2**, 43, 1859; N. R., 81, 1867.

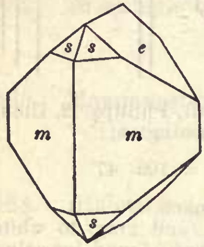
In general the mineral phosphates or arsenates were not distinctively recognized in ancient mineralogy. The species containing copper, if observed, were left to pass under the general names of *chrysocolla* and *malachites*. In 1747, Wallerius has, besides *Koppar-Lazur* or azurite, the two species Copper Green (malachite) and Copper Blue (chrysocolla and azurite in part), but without well-defined limits. Cronstedt, in 1758, describes the Mountain Blue as sometimes impure (terra calcarea mixta), and hence effervescing with aqua-fortis. Fontana, in 1778, announced the green *carbonate* after an analysis; and Bergmann in his Sciagraphia, 1782, recognizes only carbonate of copper, and calls wrongly the *green mica* of Werner (1780, and later *torbernite*) a chloride. In 1786 Klaproth analyzed an *arsenate*, and Werner soon after gave it the name of *Olivenerz;* and in Werner's system of 1789 (Bergm. J., 382, 1789), Azurite, Malachite, Copper green of compact texture not effervescing with acids (chrysocolla), and Olivenerz, together with a so-called *Eisenschüssig Kupfergrün* (mostly earthy green carbonate), were the only species. Karsten's Tabellen of 1800 contain no addition to the list. But in 1801 Bournon announced, from an analysis by Chenevix, a second arsenate, afterward called *Liroconite;* Vauquelin a third, afterward named *Chalcophyllite;* Klaproth a fourth, the *Strahliges Olivenerz*, or *Clinoclase.* Klaproth also published at the same time an analysis of the first *phosphate*, now called *Pseudomalachite;* besides one of the oxychloride *Atacamite*, which mineral had been brought from Chili as *copper sand* between 1780 and 1790, and was pronounced an oxide by Vauquelin, and a chloride by Karsten in his Tabellen of 1800.

**562. LIBETHENITE.** Olivenerz pt. Phosphorkupfererz pt. Phosphate of Copper pt. Cuivre phosphaté pt. Octaedrisches Phosphorkupfer *Leonh.*, Leonh. u. Selb's Min. Stud., 1812. Blättricher Pseudomalachite pt. *Hausm.*, Handb., 1036, 1813. Libethenit *Breith.*, Char., 267, 1823. Aphérèse *Beud.*, **2**, 569, 1832. Pseudo-libethenit *Rg.*, Min. Ch., 344, 1860.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}9601 : 1 : 0{\cdot}7019$ Rose[1].
$100 \wedge 110 = 43° 50'$, $001 \wedge 101 = 36° 10\frac{1}{6}'$, $001 \wedge 011 = 35° 4'$.

**Forms**[1]: *a* (100, $i$-$\bar{\imath}$) cleavage, *b* (010, $i$-$\breve{\imath}$); *t* (210, $i$-$\bar{2}$). *m* (110, *I*); *δ* (310 $i$ $\bar{3}$). *e* (011, 1-$\breve{\imath}$), *s* (111, 1).

Angles: $tt''' = 51° 17'$, $mm''' = {}^*87° 40'$. $\delta\delta' = 35° 30'$. $ee' = {}^*70° 8'$, $me = 66° 33'$; $ss' = 61° 47\frac{1}{2}'$, $ss'' = 90° 46$, $ss''' = 59° 4\frac{1}{2}'$.



In crystals usually small, short prismatic in habit; often united in druses. Also globular or reniform and compact.

Cleavage: *a*, *b* very indistinct. Fracture subconchoidal to uneven. Brittle. H. = 4. G. = 3·6–3·8. Luster resinous. Color olive-green, generally dark. Streak olive-green. Translucent to subtranslucent.

Optically —. Ax. pl. ∥ *c*. Bx ⊥ *b*. Dispersion $\rho > v$ large. Axial angles, Dx.[2]:

$2H_{a.r} = 101° 42'$ $2H_{o.r} = 127° 47'$ $\therefore 2V_r = 81° 38'$ $\beta_r = 1{\cdot}739$
$2H_{a.y} = 101° 8'$ $2H_{o.y} = 128° 56\frac{2}{3}'$ $\therefore 2V_y = 81° 8'$ $\beta_y = 1{\cdot}743$
$2H_{a.bl} = 99° 59'$ $2H_{o.bl} = 130° 22\frac{2}{3}'$ $\therefore 2V_{bl} = 80° 20'$ $\beta_{bl} = 1{\cdot}755$

**Comp.**—$Cu_3P_2O_8.Cu(OH)_2$ or $4CuO.P_2O_5.H_2O$ = Phosphorus pentoxide 29·8, cupric oxide 66·4, water 3·8 = 100.

**Anal.**—Kühn, Lieb. Ann., **51**, 124, 1844.

$P_2O_5$ 29·44 CuO 66·94 $H_2O$ 4·05 = 100·43

Other analyses (5th Ed., p. 563) agree closely, except one by Berthier which yielded 7·4 p. c. $H_2O$; this mineral is called *Pseudo-libethenite* by Rammelsberg, who writes the formula $Cu_3P_2O_8.Cu(OH)_2.H_2O$. Beudant cites the same analysis in connection with his name Aphérèse.

**Pyr., etc.**—In the closed tube yields water and turns black. B.B. fuses at 2 and colors the flame emerald-green. On charcoal with soda gives metallic copper, sometimes also an arsenical odor. Fused with metallic lead on charcoal is reduced to metallic copper, with the formation of lead phosphate, which treated in R.F. gives a crystalline polyhedral bead on cooling. With the fluxes reacts for copper. Soluble in nitric acid.

**Obs.**—Occurs in cavities in quartz, associated with chalcopyrite, at Libethen, near Neusohl, in Hungary; at Rheinbreitenbach and Ehl on the Rhine; at Nizhni Tagilsk in the Ural; in Bolivia, S. A., with malachite; at the Mercedes mine, near Coquimbo, Chili, with tagilite and limonite; also in small quantities near Gunnis Lake in Cornwall, and near Redruth.

**Artif.**—Cf. Friedel and Sarasin, Bull. Soc. Min., **2**, 157, 1879.

**Ref.**—[1] Hungary, Reis. Ural, **1**, 316, 1837. For Uralian crystals he obtained $mm''' = 84° 36'$, $ee' = 69° 19'$. Cf. Schrauf, Zs. **Pyr., etc.**—Heated in a closed tube decrepitates feebly, and yields a little water, becoming white and porcelanous. On charcoal fuses, producing a coating of zinc oxide, and a feeble odor of arsenic. In a closed tube with soda and charcoal gives a ring of arsenic. With borax in O.F. pearl-yellow while hot, colorless on cooling. Easily soluble in dilute hydrochloric acid.

**Obs.**—From Chañarcillo, Chili, with limonite and native silver. At Cap Garonne near Hyères, France. At the ancient zinc mines of Laurium, Greece, filling drusy cavities in a cellular smithsonite. Named after M. Adam, the mineralogist, of Paris.

**Ref.**—[1] Chañarcillo, N. R., 26, 1867; Laurium crystals gave *mm'''* = 89° 50'–88° 40' and *dd'* = 72° 20', also *mm'''* = 88° 20'–88° 30'. Bull. Soc. Min., **1**, 30, 1878.

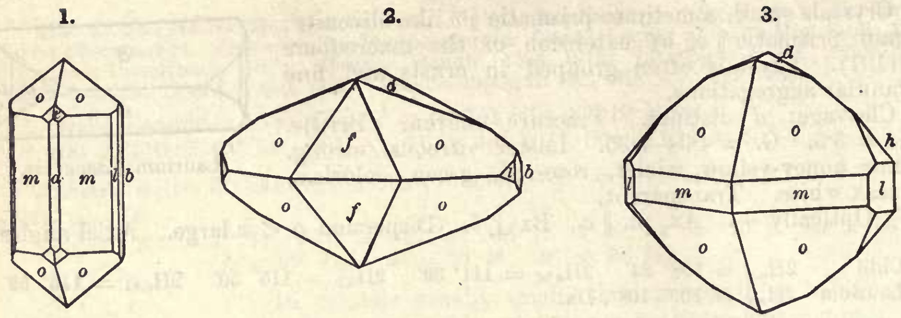

Figs. 1–3, Lake Valley, N. Mexico, Rath.

Crystals usually small, short prismatic ‖ *m* or *l* (130), or pyramidal, *o* (111). Faces seldom perfectly smooth; *l* strongly striated vertically; *f* (201) dull and striated ‖ *f*/*f‴*, *o* (111), *d* (012) bright. The crystals forming drusy surfaces and crusts, also in stalactitic aggregates. Also massive, fibrous radiated with mammillary surface.

Cleavage none. Fracture small conchoidal to uneven. Brittle. H. = 3·5. G. = 5·9–6·2. Luster greasy. Color columbine- or cherry-red, brownish red, hair-brown, reddish chestnut-brown, blackish brown, black. Streak orange to brownish red or yellowish gray. Transparent to nearly opaque.

Ax. pl. ‖ *b*. Bx ⊥ *c* negative, Bx ⊥ *a* positive; axial angle very large, the interference-rings hardly visible in oil.

**Comp., Var.**—$R_3V_2O_8.R(OH)_2$ or $4RO.V_2O_5.H_2O$; R = Pb, Zn chiefly and usually in the ratio 1 : 1 approx.; the percentage composition is then: Vanadium pentoxide 22·7, lead protoxide 55·4, zinc oxide 19·7, water 2·2 = 100. Copper is also sometimes present, and further arsenic replacing vanadium.

**Var.**—1. *Ordinary*, containing lead and zinc. Usually in distinct crystals as described. G. = 5·9–6·1.

2. *Cuprodescloizite*, containing copper in considerable amount; this variety also carries arsenic. It usually appears in crusts or reniform masses with mammillary surface and fine columnar structure, somewhat divergent or radiating. Color dull green to greenish black, yellowish brown. G. = 6·1–6·2.

[a] $Mn_2O_3$.

[1] X = $SiO_2$ 0·18, CaO 0·10, MgO 0·06. [2] X = Cl 0·04, $SiO_2$ 1·01, CaO 0·04, MgO 0·03.
[3] X = Cl 0·07, $SiO_2$ 0·80, CaO 1·01, MgO 0·04, $K_2O$ 0·10, $Na_2O$ 0·17, $CO_2$ 0·82.

The material of anal. 2-4 contained some vanadinite.

Frenzel's analysis of *tritochorite* is as follows: $V_2O_5$ 24·41, $As_2O_5$ 3·76, PbO 53·90, ZnO 11·06, CuO 7·04 = 100·17. There is no question as to its identity with cuprodescloizite; he has since stated that the water present was neglected or overlooked.

**Pyr., etc.**—In the closed tube gives water. B.B. on charcoal fuses, and is partially reduced to a globule of metallic lead enveloped in a black scoria. With borax in R.F. a green glass, and with niter in O.F. a violet color due to manganese. With salt of phosphorus in R.F. a glass of a chrome-green color, which is orange-yellow in the O.F. Dissolves in cold dilute nitric acid.

**Obs.**—Occurs in small crystals, 1 to 2 mm. thick, clustered on a siliceous and ferruginous gangue from S. America, at the Venus mine and other points in the Sierra de Córdoba, Argentine Republic, associated with acicular green pyromorphite, vanadinite, etc. At Kappel in Carinthia, in small clove-brown rhombic octahedrons, with G. = 5·83 (*vanadite* of Zippe, cf. Schrauf, Pogg., **116**, 355, 1862).

Sparingly at the Wheatley mine, Phenixville, Penn., as a thin crystalline crust on wulfenite, quartz, and a ferruginous clay (J. L. Smith, confirmed by Genth). Abundant at the Sierra Grande mine, Lake Valley, Sierra Co., New Mexico, in red to nearly black crystals, pyramidal and prismatic in habit, associated with vanadinite, iodyrite, etc.; at the Mimbres and other mines, near Georgetown, New Mexico, in stalactitic crystalline aggregates. In Arizona near Tombstone; in Yavapai Co., in brownish olive-green crystals; at the Mammoth Gold mine, near Oracle, Pinal Co., in orange-red to brownish red crystals with vanadinite and wulfenite.

A vanadate probably identical with descloizite occurs at the Mayflower mine, Bald Mountain distr., in Beaverhead Co., Montana, see anal. 7; it is in an impure earthy form of a dull yellow to pale orange color. The water present is double in amount that required by normal descloizite, but in view of the nature of the material this may not be significant; cf. brackebuschite beyond.

A massive variety, containing copper, in crusts and reniform masses with radiated structure occurs in San Luis Potosi, also in a vein of argentiferous galena in Zacatecas (Pisani), Mexico; it has been variously named *tritochorite, cuprodescloizite. ramirite*. A similar variety occurs as an incrustation on quartz at the Lucky Cuss mine, Tombstone, Cochise Co., Arizona.

Named after the French mineralogist. A. Des Cloizeaux. *Ramirite* is after the Mexican mining engineer Santiago Ramirez. *Tritochorite*, from *τρίτος, third*, and *χωρεῖν, to follow*, was given on the supposition that the mineral formed a third member of a series with eusynchite and aræoxene.

**Ref.**—[1] N. Mexico, Zs. Kr., **10**, 464, 1885. The form was made monoclinic by Websky, Ber. Ak. Berlin, 672, 1880, Zs. Kr., **5**, 542, 1881; the orthorhombic character is established by Des Cloizeaux, Bull. Soc. Min., **9**, 138, 191, 1886. See earlier Dx., Ann. Ch. Phys., **41**, 78, 1854.

---

The pages immediately following contain descriptions of several other vanadates of more or less uncertain composition and probably in part to be united with descloizite.

EUSYNCHITE *Fischer & Nessler*, Ber. Ges. Freiburg, 1854, Jb. Min., 570, 1855. Aræoxen *Kbl.*, J. pr. Ch., **50**, 496, 1850.

Massive: in nodular, stalactitic forms. H. = 3·5. G. = 5·596. Luster resinous. Color yellowish red, reddish brown, greenish. Streak orange-yellow to pale yellow.

Composition, perhaps $R_3V_2O_8$ with R = lead, zinc, and sometimes copper, and the vanadium in part replaced by arsenic. It is to be noted, however, that the analyses are unsatisfactory, and the mineral may contain water like the so-called tritochorite which was originally described as anhydrous and belonging to this series. If this is the case eusynchite would be simply identical with descloizite.

Sandberger has recently made it almost certain that aræoxene is only descloizite; he quotes Pecher as having found 3·2 p. c. $H_2O$ in the original mineral. Jb. Min., **1**, 258, 1889.

Anal.—1, Rg., Ber. Ak. Berlin, 40, 1864. 2, Id., Min. Ch. Erg., 91, 1886. 3, 4, Czudnowicz, Pogg., **120**, 26, 1863; Rg., Min. Ch., 290, 1875. 5, Bergemann, Jb. Min., 397, 1857, and Rg., ib., 291.

| | | $V_2O_5$ | $As_2O_5$ | $P_2O_5$ | PbO | ZnO | CuO | |
|---|---|---|---|---|---|---|---|---|
| 1. Hofsgrund | G. = 5·596 | [24·22] | 0·50 | 1·14 | 57·66 | 15·80 | 0·68 | = 100 |
| 2. " | G. = 5·462 | *undet.* | — | 1·54 | 57·38 | 16·27 | — | |
| 3. " | | 24·32 | — | *tr.* | 58·35 | 17·33 | — | = 100 |
| 4. " | | 20·28 | — | *tr.* | 57·06 | 22·66 | — | = 100 |
| 5. *Aræoxene* | | 17·04 | 10·66 | — | 53·26 | 18·36 | — | = 99·32 |

From 3, 3·2 p. c. $SiO_2$ and from 4, 5·5 $SiO_2$ have been deducted; from 5, 1·34 p. c. gangue.

Eusynchite is from Hofsgrund near Freiburg in Baden; aræoxene from Dahn near Nieder-Schlettenbach, Rhenish Bavaria, with dechenite.

DECHENITE, vanadinsaures Bleioxyd *C. Bergemann*, Pogg., **80**, 393, 1850.

Massive, botryoidal, nodular, stalactitic; sometimes traces of a columnar structure. H. = 3–4. G. = 5·6–5·81. Luster of fresh fracture greasy. Color fine deep red to yellowish red and brownish red; also leather-yellow. Streak orange-yellow to ocher- and pale yellow.

Composition usually accepted as $PbV_2O_6$ or $PbO.V_2O_5$ = Vanadium pentoxide 45·0, lead protoxide 55·0 = 100. The old analyses, however, are faulty, for the mineral contains zinc as shown by Brush (Am. J. Sc., **24**. 116, 1857). and Pisani (Bull. Soc. Min., **12**, 40, 1889). New analyses may prove that the composition is essentially the same as that of eusynchite and aræoxene, and like them it may have to be united with descloizite.

Analyses.—1–3, Bergemann, l. c. 4, Nessler [Ber. Ges. Freiburg, 1854] Rg., Min. Ch., 311, 1860.

| | $V_2O_5$ | PbO | |
|---|---|---|---|
| 1. Dahn, *dark red cryst.* | 47·16 | 52·92 | = 100·08 |
| 2. " " " " | 46·10 | 53·72 | = 99·82 |
| 3. " *ywh. verruciform* | 49·27 | 50·57 | = 99·84 |
| 4. Zähringen G. = 4·945? | 45·12 | 55·70 | = 100·82 |

Pyr., etc.—B.B. fuses easily without decrepitation to a yellow glass. On charcoal in R.F. gives lead globules and a white coating, which, treated with cobalt solution, becomes green (zinc). With salt of phosphorus and borax gives an emerald-green bead in R.F., becoming yellowish green to yellow in O.F. Decomposed by hot hydrochloric acid, yielding an emerald-green solution. This treated with alcohol, boiled and decanted from the separated lead chloride, yields, after evaporation, a solution which, diluted with water, has an azure-blue color (v. Kobell).

Occurs with other ores of lead near Nieder-Schlettenbach in the Lauterthal, Rhenish Bavaria. A lead vanadate occurs with the lead ores at Leadville, Col. (Iles, Am. J. Sc., **23**, 381, 1882), and it has been suggested that this may be dechenite; it is, however, probably descloizite.

Named after the German geologist, Heinrich von Dechen (1800–1889).

**565. CALCIOVOLBORTHITE.** Kalk-volborthit *Credner*, Pogg., **74**, 546, 1848. Calciovolborthite *A. D'Achiardi*, I Metalli, **2**, 492, 1883. Calcvolvorthite *Adam*, Tabl. Min., 33, 1869.

Occurs in two varieties: (1) green, in thin tables, cleaving easily in one direction, greenish yellow in streak, pearly in luster, with G. = 3·495; (2) gray, fine crystalline granular, brownish yellow in streak, with H. = 3·5, and G. = 3·860.

**Comp.**—Probably $(Cu,Ca)_3V_2O_8.(Cu,Ca)(OH)_2$ or $4(Cu,Ca)O.V_2O_5.H_2O$; if Cu : Ca = 3 : 2, this requires: Vanadium pentoxide 38·0, cupric oxide 39·6, lime 18·6, water 3·8 = 100.

**Anal.**—Credner, l. c.

| 1. *Green* | G. = 3·495 | ⅔ | 36·58 | 44·15 | 12·28 | 0·50 | 0·40 | 4·62 | gangue 0·10 | = 98·63 |
| 2. *Light green* | | | [36·91] | 38·90 | 17·40 | 0·87 | 0·53 | 4·62 | " 0·77 | = 100 |
| 3. *Gray* | G. = 3·860 | | 39·02 | 38·27 | 16·65 | 0·92 | 0·52 | 5·05 | " 0·76 | = 101·19 |

The results correspond most nearly with the formula above given. The ratio of Cu to Ca in No. 1 is about 5 : 2; and in 2 and 3, 3 : 2.

**Obs.**—From Friedrichsrode, Thuringia. For the ordinary volborthite see p. 838.

**566. BRACKEBUSCHITE.** *Doering*, quoted by Rg., Zs. G. Ges., **32**, 711, 1880; also Bol. Acad. Cienc. Córdoba, **5**, 501, 1883.

In groups of small prismatic crystals flattened and vertically striated; monoclinic? Color black, reddish by transmitted light. Streak yellow. Translucent to nearly opaque.

Optically − ? Ax. pl. ⊥ striations. Bx (obtuse?) oblique to the large face of the crystals. Ax. angle large, Dx. (quoted by Pisani).

**Comp.**—Perhaps $R_3V_2O_8 + H_2O$ with R = Pb chiefly, also Fe, Mn ; if 4 : 1 : 1 = Vanadium pentoxide 25·4, lead protoxide 62·1, iron protoxide 5·0, manganese protoxide 5·0, water 2·5=100.

If this composition is confirmed brackebuschite belongs with the hydrous phosphates, etc., near hopeite, p. 808.

**Anal.**—1, Doering, quoted by Rg., l. c., after deducting 4·36 insol. 2, 3, Doering, l.c., 1883.

| | $V_2O_5$ | $As_2O_5$ | $P_2O_5$ | PbO | ZnO | CuO | FeO | MnO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 25·32 | — | 0·18 | 61·00 | 1·29 | 0·42 | 4·65 | 4·77 | 2·03 | = 99·66 |
| 2. | 24·22 | 0·17 | | 58·34 | — | — | 5·78[a] | 5·54[b] | 1·94 | insol. 3·40 = 99·39 |
| 3. | 24·74 | 0·11 | — | 58·02 | 1·23 | 0·41? | 4·46 | 4·56 | 2·43 | X[c] 1·29, insol. 3·07 = 100·32 |

[a] And $Fe_2O_3$. [b] And $Mn_3O_4$. [c] $Fe_2O_3 + Mn_3O_4$.

The above analyses agree tolerably well with that of Damour of descloizite (ref. on p. 787) as recalculated by Rg., l. c., deducting obvious impurities (3·44 p. c. sand), viz.:

| $V_2O_5$ | PbO | ZnO | CuO | $Fe_2O_3$ | $Mn_2O_3$ | $H_2O$ | Cl | |
|---|---|---|---|---|---|---|---|---|
| 24·80 | 60·40 | 2·25 | 0·99 | 1·65 | 6·52 | 2·43 | 0·35 | = 99·39 |

It is to be noted, however, that Damour regarded the oxides of manganese, iron, copper also as impurities, so that the result is doubtful at best.

Groth suggests that brackebuschite may be the monoclinic equivalent of descloizite, but the evidence now in hand gives it another formula.

**Obs.**—Occurs with descloizite and vanadinite, at several localities in the State of Córdoba, Argentine Republic. Named for Dr. D. Luis Brackebusch, of Buenos Aires.

**567. PSITTACINITE.** *F. A. Genth*, new tellurate of lead and copper, Proc. Am. Phil. Soc., **14**, 229, 1874; Id., Am. J. Sc., **12**, 35, 1876.

In thin crypto-crystalline coatings, sometimes small mammillary or botryoidal; also pulverulent.

Color siskin- to olive-green, sometimes with grayish tint.

**Comp.**—Perhaps, as suggested by Rg., $R_3V_2O_8.R(OH)_2.H_2O$ or $4RO.V_2O_5.2H_2O$, with R = Pb : Cu = 1 : 1, hence requiring: Vanadium pentoxide 22·2, lead protoxide 54·1, cupric oxide 19·3, water 4·4 = 100.

Genth deduces for anal. 1: the mean oxygen ratio for Pb : Cu : V : H = 1 : 0·98 : 2·25 : 2·15 = 9 : 9 : 20 : 18, corresponding to the formula $3Pb_3V_2O_8.Cu_3V_2O_8.6Cu(OH)_2.12H_2O$, for which he calculates: $V_2O_5$ 19·3, PbO 53·2, CuO 18·9, $H_2O$ 8·6 = 100. This, however, is not far from $5RO.V_2O_5.5H_2O$. Other analyses give much less water.

**Anal.**—1, Genth, l. c., after deducting impurities (see below). 2–4, Doering. Bol. Acad. Cienc. Córdoba, **5**, 506, 1883. 5, 6, Doering, as recalc. by Rg., after deducting gangue, cerussite, malachite, etc., Min., Ch. Erg., 189, 1886. 7, Pisani, C. R., **92**, 1292, 1881.

| | $V_2O_5$ | $As_2O_5$ | $P_2O_5$ | PbO | CuO | ZnO | $Fe_2O_3$ | $H_2O$ | |

| 7. Laurium | 25·53 | — | — | 50·75 | 18·40 | 1·53[b] | — | 4·25 | = 100·46 |

[a] Incl. $CO_2$ [b] CaO.

From anal. 1, 22 p. c. impurities have been deducted ($SiO_2$ 15·13, $Fe_2O_3$ 2·72, $Al_2O_3$ 1·29, CaO,MgO 2·86); other analyses on material with 7·60 to 48·84 p. c. gangue agreed with 1.

**Pyr., etc.**—B.B. fuses easily to a black, shining mass. Reacts for lead, copper, and vanadium with the fluxes. Soluble in dilute nitric acid.

**Obs.**—Occurs associated with gold, cerussite, chalcopyrite, and limonite, on quartz, at the Iron Rod mine and New Career mine, in the Silver Star District, Montana; also probably the same mineral in the province of San Luis, near Las Cortaderas, east of Villa San Martin, Argentine Republic, as a crystalline incrustation on quartz with vanadinite. A vanadate from Laurium, Greece (anal. 7), seems to belong here (Rg., Pisani). Named from *psittacinus*, siskin- or parrot-green.

Mottramite *H. E. Roscoe*, Proc. Roy. Soc., **25**, 111, 1876.

In thin crystalline incrustations, occasionally in distinct, minute crystals, also compact. H. = 3. G. = 5·894. Luster resinous. Color velvety black; in thin sections yellow. Streak yellow. Translucent.

A vanadate of lead and copper. Roscoe calculates $R_3V_2O_8.2R(OH)_2$, which corresponds to dihydrite and erinite. If R = Pb : Cu = 1 : 1, the percentage composition is: Vanadium pentoxide 18·7, lead protoxide 57·2, cupric oxide 20·4, water 3·7 = 100. Rg., however, suggests $R_3V_2O_8.3R(OH)_2$. The imperfect analysis, with a loss of 3 p. c., makes the result doubtful. It seems not improbable that it may be identical with psittacinite.

Analysis.—1, Roscoe. 2, the same, after deducting impurities:

| | $V_2O_5$ | PbO | CuO | $\underbrace{FeO, ZnO, MnO}$ | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 1. | $\frac{3}{2}$ 17·14 | 50·97 | 19·10 | 2·52 | 0·26 | 2·13 | 3·63 hygr. water 0·22, $SiO_2$ 1·06=97·03 |
| 2. | 18·87 | 56·12 | 21·02 | — | — | — | 3·99 = 100 |

**Obs.**—Occurs on the Keuper Sandstone, at Alderley Edge, and at Mottram St. Andrew's, Cheshire, England.

Chileite *Kenngott*, Mohs'sche Min., 28, 1853. Vanadate of Lead and Copper *Domeyko* Ann. Mines, **14**, 150, 1848 Vanadinkupferbleierz. Cuprovanadite *Adam*, Tabl. Min., 33, 1869.

An ore having a dark brown or brownish black color, and observed only in an earthy state, looking much like a ferruginous clay or earth. It occurs in cavities in an arseno-phosphate of lead along with amorphous carbonates of lead and copper.

An uncertain vanadate of lead and copper. Analyses by Domeyko, l. c.:

| | $V_2O_5$ | $As_2O_5$ | $P_2O_5$ | CuO | PbO | $PbCl_2$ | CaO | $Fe_2O_3, Al_2O_3$ | $SiO_2$ | $H_2O$ | clay | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | 13·5 | 4·6 | 0·6 | 14·6 | 54·9 | 0·3 | 0·5 | 3·5 | 1·0 | 2·70 | 1·0 | = 97·2 |
| 2. | 13·33 | 4·68 | 0·68 | 16·97 | 51·97 | 0·37 | 0·58 | 3·42 | 1·33 | 2·70 | 1·52 | = 97·55 |

B.B. fuses easily, and affords a black pearl, a little blebby; gives a clear green pearl with salt of phosphorus or borax, and a globule of lead containing copper on charcoal. In nitric acid easily soluble.

This ore occurs at the silver mine called Mina Grande, or Mina de la Marqueza, in Chili; it has been worked for copper and silver.

*Vanadate from the Lake Superior Copper Region.* An ore similar in color and clayey appearance to Domeyko's mineral has been announced by J. E. Teschemacher among specimens from the Cliff mine, in the Lake Superior Copper Region. The presence of vanadium was ascertained by both blowpipe and acid tests. The color is a dark chocolate, and also a bright yellow. The exact state of composition of the vanadic acid is doubtful. There is no lead oxide in the ore, and the brown variety is mixed with an earthy iron oxide; when carefully separated from the gangue it was found to contain no copper. This Min., 531, 1850.

Vanadiolite *Hermann*, J. pr. Ch., **1**, 445, 1870.

Form not determined. Occurs in small crystals, partly in druses. Color dark green, almost black, in small fragments dark emerald-green. Streak grayish green. Luster vitreous, brilliant. G. = 3·96. Analysis gave:

$V_2O_5$ 44·85 $SiO_2$ 15·61 $Al_2O_3$ 1·10 FeO 1·40 CaO 34·43 MgO 2·61 = 100

B.B. fuses to a black slag with cauliflower-like intumescence. With salt of phosphorus gives a dark green bead, and a silica skeleton. Decomposed on fusion with a mixture of sodium carbonate. From the Sliudianka river near Lake Baikal in Siberia, associated with lavroffite.

A doubtful substance, regarded by Rammelsberg as a mixture of augite and a vanadate.

Wicklowite. Vichlovite *A. D'Achiardi*, I Metalli, **2**, 568, 1883. A doubtful lead vanadate, apparently that mentioned by Thomson (Min., 574, 1836) as said to have come from Wicklow county, Ireland.

---

### 568. ERINITE. *Haidinger*, Phil. Mag., 4, 154, 1828.

In mammillated crystalline groups, concentric in structure and fibrous, and rough from the terminations of very minute crystals; the concentric layers compact, and often easily separable.

Cleavage in one direction in traces. Brittle. H. = 4·5–5. G. = 4·043. Luster almost dull, slightly resinous. Color fine emerald-green, slightly inclining to grass-green. Streak green, paler than the color. Subtranslucent to nearly opaque.

**Comp.**—$Cu_3As_2O_8.2Cu(OH)_2$ or $5CuO.As_2O_5.2H_2O$ = Arsenic pentoxide 34·7, cupric oxide 59·8, water 5·4 = 100.

There is some question as to the amount of water present.

**Anal.**—1, Turner, Phil. Mag., **4**, 155, 1828. 2, 3, Pearce, Proc. Col. Soc., **2**, 150, 1886. 4, 5, Hillebrand, Am. J. Sc., **35**, 399, 1888.

| | $As_2O_5$ | CuO | ZnO | $H_2O$ |
|---|---|---|---|---|
| 1. Cornwall | 33·78 | 59·44 | — | 5·01 $Al_2O_3$ 1·77 = 100 |

| 4. " | 33·53 | 57·67 | 1·06 | 7·22 $P_2O_5$ 0·10, $Fe_2O_3$ 0·14, CaO 0·32 = 100·04 |
| 5. " | 31·91 | 57·51 | 0·59 | 9·15 $Fe_2O_3$ 0·20, CaO 0·51 = 99·87 |

**Pyr., etc.**—In the closed tube decrepitates and yields water. B.B. on charcoal emits arsenical fumes and fuses, giving an arsenide, which in O.F. yields a globule of copper. Soluble in nitric acid.

**Obs.**—Stated by Haidinger to come from the county of Limerick, Ireland; but shown by Church to be a Cornish species.

Occurs with olivenite and implanted upon clinoclasite, azurite, enargite, or barite at the American Eagle and Mammoth mines, Tintic district, Utah.

Erinite of Beudant (1832), Des Cloizeaux (1845), Schrauf (1860) is chalcophyllite.

**569. DIHYDRITE.** *Hermann*, J. pr. Ch., **37**, 178, 1846. Pseudomalachite, Phosphorchalcite, Phosphorkupfer pt. See also Pseudomalachite, p. 794.

Monoclinic or triclinic. Axes $\bar{a} : \breve{b} : \acute{c} = 2{\cdot}8252 : 1 : 1{\cdot}53395$; $\alpha = 89° 29\frac{1}{2}'$, $\beta = 91° 0\frac{1}{2}'$, $\gamma = 90° 39\frac{1}{2}'$ Schrauf[1].

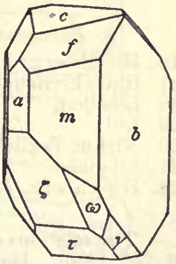
Crystals monoclinic in habit with embedded tw. lamellæ ∥ *a*; also tw. pl. *b* (cf. Schrauf). Crystals often united in aggregates with drusy surface or in hemispherical forms; also lamellar; reniform or massive with concentric structure; indistinctly fibrous.



Ehl, Schrauf.

Cleavage: *b* imperfect. Fracture small conchoidal to uneven. Brittle. H. = 4·5–5. G. = 4–4·4. Luster adamantine, inclining to vitreous. Color dark emerald-green. Streak green, a little paler than the color. Translucent to subtranslucent.

Pleochroism distinct: 𝔠 deep bluish green, 𝔟 yellowish green, 𝔞 bluish green. Optically −. $Bx_a \perp t$ (101) approx., and inclined + 68½° to normal to *a*. $Bx_o$ nearly ⊥ *b*; but inclined at a maximum 5½°.

**Comp.**—Essentially $Cu_3P_2O_8.2Cu(OH)_2$ or $5CuO.P_2O_5.2H_2O$ = Phosphorus pentoxide 24·7, cupric oxide 69·0, water 6·3=100.

**Anal.**—See anals. 1–3, under pseudomalachite, p. 794.

**Pyr., etc.**—Like libethenite.

**Obs.**—The distinctly crystallized forms of pseudomalachite, lunnite, or phosphocalchite, as the group has been variously called, are here included. The typical localities are: Ehl near Linz on the Rhine; Rheinbreitenbach; also Nizhni Tagilsk, in the Ural.

**Ref.**—Zs. Kr., **4**, 1 *et seq.*, 1879.

**570. PSEUDOMALACHITE.** Phosphorsaures Kupfer pt. *Karst.*, *Klapr.*, N. Schrift. Berl. Ges. Nat. Fr., 3, 304, 1801. Phosphorkupfer *id.*, Tab., 64, 97, 1808. Phosphorkupfererz *Wern.* Cuivre phosphaté *H.*, Tabl., 92, 1809. Phosphate of copper. Pseudomalachit *Hausm.*, Handb., 1035, 1813. Phosphorochalcit *Glocker*, Handb., 847, 1831. Ypoléime *Beud.*, Tr., **2**, 570, 1832. Ehlit, Prasin-chalzit, *Breith.*, Char., 45, 49, 1832. Lunnit *Bernhardi.* Kupferdiaspore *Kühn*, Lieb. Ann., **51**, 125, 1844.

Usually massive, reniform, and botryoidal, with a radiating fibrous structure. H. = 4·5–5. G. = 3·4–4·4. Luster vitreous. Color dark emerald-green, verdigris-green, blackish green, often darker on the surface. Streak paler green.

**Comp.**—In part $Cu_3P_2O_8.3Cu(OH)_2$ or $6CuO.P_2O_5.3H_2O$ = Phosphorus pentoxide 21·2, cupric oxide 70·8, water 8·0 = 100. Here belongs ordinary amorphous pseudomalachite. Perhaps also $Cu_3P_2O_8.2Cu(OH)_2.H_2O$ or $5CuO.P_2O_5.3H_2O$ = Phosphorus pentoxide 24·0, cupric oxide 66·9, water 9·1 = 100. To the mineral with the latter composition the name *Ehlite* is ordinarily given.

Dihydrite, ehlite, pseudomalachite form a closely related series of phosphates of copper, but their relations are not entirely certain (cf. Schrauf, below). The first occurs in distinct crystals and is set apart as an independent species; the others are only known in fibrous, foliated, or massive forms.

The relations of these phosphates of copper have been studied by Schrauf (Zs. Kr., **4**, **1879**, **8**, 231, 1883). He embraces the whole group under the name Lunnite. For the crystalline varieties, which he makes pseudo-monoclinic (triclinic), with G. = 4·4, and corresponding mostly to $Cu_5P_2H_4O_{12}$, he uses the name *dihydrite* (D); they show no loss at 200°. The names *ehlite* (E) and *phosphorocalcite* (P) he gives to the compounds $Cu_5P_2H_6O_{13}$ and $Cu_5P_2H_8O_{14}$, respectively, and he regards the three as entering in varying proportions to form the different massive varieties; the latter have a lower specific gravity, and lose water on ignition at 200°.

According to Schrauf's view, anal. 3 corresponds to a molecular mixture of 3D + 1P; 15, after deducting 8·8 p. c. chrysocolla, to simply "dihydrite;" 20 to D + E + P; 21 to 4P + 2E + D; where the letters D, E, P have the values explained above. The value of this complex hypothesis, especially in view of the uncertain homogeneity of much of the material analyzed, seems doubtful.

All these compounds are embraced, in the 5th Edition, under the name *pseudomalachite* of Hausmann, which is the earliest of the names of this species, and is as short and as good as the later *Phosphorochalcite* of Glocker. *Lunnite* was substituted by Bernhardi, and has been used in some recent works, also by Schrauf (1879). But Lunn's one analysis (see below) was not made until 1821, and gives a different composition from that since obtained.

**Pyr.**—Like libethenite.

**Obs.**—Occurs in veins traversing slate at Virneberg, near Rheinbreitenbach, and at Ehl, near Linz, on the Rhine, along with other copper ores; at Hirschberg in Voigtland; Libethen in Hungary; Kreuzberg in Bohemia; Nizhni Tagilsk in the Ural. Also in Cornwall, in minute globular concretions. Also met with in the Perkiomen mine, Pa.; in Cabarras Co., N. C.

The phosphates of copper were included in the olivenerz and malachite of the mineralogists of last century, cf. p. 785.

A hydrous cupric phosphate from Phillipsburg, Montana, gave Pearce: $P_2O_5$ 20·10, CuO 62·56, $H_2O$ [17·34] = 100. Proc. Col. Sc. Soc., **1**, 119, 1884.

Rev. F. Lunn obtained for an ore from Rheinbreitenbach (Ed. Phil. J., **5**, 211, 1821): $P_2O_5$ 21·69, CuO 62·85, $H_2O$ 15·45 = 99·99, giving the formula $5CuO.2P_2O_5.5H_2O$. But no later analyst has found as much water. Beudant cites this analysis under his *ypoleime.*

**571. CLINOCLASITE.** Strahliges Olivenerz *Karst.*, Klapr., N. Schrift. Berl. Ges. Fr., 3, 298, 1801. Cupreous Arsenate of Iron *Bourn.*, Phil. Trans., 1801 (with anal. by Chenevix). Strahlenerz *Karsten*, Tab., 64, 97. 1808. Cuivre arseniaté férrifère *H.*, Tabl., 91, 1809. Strahlenkupfer *Hausm.*, Handb., 1050, 1813. Strahlerz *Wern.* Klinoklas *Breith.*, Uib., 1830. Siderochalcit *Glocker*, Grundr., 840, 1831. Aphanèse *Beud.*, Tr., **2**, 602, 1832. Aphanesite *Shep.*, Min., 1835. Abichit *Bernhardi*, Glocker's Grundr., 579, 1839.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 1·9069 : 1 : 3·8507$; $\beta = {}^*80° \; 30' = 001 \wedge 100$ Phillips[1].

$100 \wedge 110 = 62° \; 0'$, $001 \wedge 101 = 56° \; 12'$, $001 \wedge 011 = 75° \; 15'$.

**Forms**[1]: *a* (100, *i*-$\bar{i}$), *c* (001, *O*); *m* (110, *I*); *r* (101, − 1-$\bar{i}$), *s* ($\bar{3}02$, $\frac{3}{2}$-$\bar{i}$), *p* ($\bar{1}13$, $\frac{1}{3}$)[2], *t* ($\bar{1}11$, 1)[2].

$mm''' = 124°$ $cs = {}^*80° \; 30'$ $ct = 81° \; 10'$ $tt' = 122° \; 7'$
$mm' = {}^*56°$ $cm = 85° \; 33'$ $pp' = 97° \; 32'$ $m's = 63° \; 39'$
$ar = 24° \; 18'$ $cp = 58° \; 7\frac{1}{2}'$

Crystals prismatic (*m*); also elongated ∥ $\overset{|}{b}$; sometimes in acute forms, rhombohedral in aspect (f. 2). Faces rounded or uneven. Often grouped in nearly parallel position and further inclined both in the direction of the axes $\grave{c}\,\overset{|}{b}$ and $\grave{c}\,\grave{a}$, yielding finally spherical forms bounded by the curving basal faces. Also massive, hemispherical, or reniform; structure radiated fibrous.

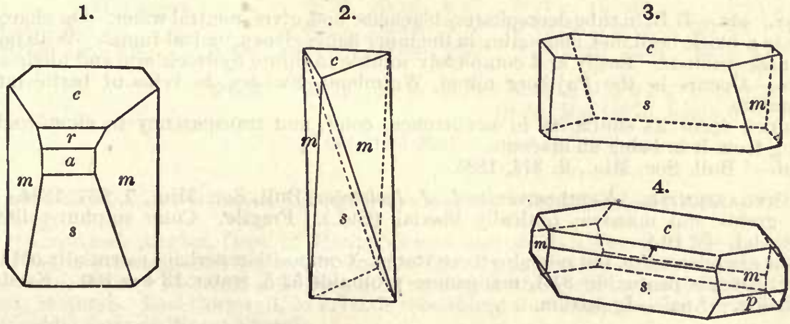

Fig. 1, Cornwall, after Phillips. 2–4, Utah. 3, 4, Washington.

Cleavage: *c* highly perfect. Brittle. H. = 2·5–3. G. = 4·19–4·36; 4·36, 4·38 Utah. Luster: *c* pearly; elsewhere vitreous to resinous. Color internally dark verdigris-green; externally blackish blue-green. Streak bluish green. Subtransparent to translucent.

Optically —. Ax. pl. ‖ *b*. Bx inclined about 90° to *à*. Dispersion $\rho < v$ very large, inclined small. Axial angles somewhat variable, Dx.:

(1) $2H_{a \cdot gr} = 81° \ 56'$ ∴ $2E_{gr} = 134° \ 36'$ (2) $2H_{a \cdot gr} = 84° \ 12'$ ∴ $2E_{gr} = 141° \ 14'$
(1) $2H_{a \cdot bl} = 83° \ 42'$ ∴ $2E_{bl} = 160° \ 52'$ (2) $2H_{a \cdot bl} = 86° \ 42'$ ∴ in air total reflection.

**Comp.**—$Cu_3As_2O_8.3Cu(OH)_2$ or $6CuO.As_2O_5.3H_2O$ = Arsenic pentoxide 30·3, cupric oxide 62·6, water 7·1 = 100.

**Anal.**—1, Rg., Min. Ch., 378, 1860. 2, Damour, Ann. Ch. Phys., **13**, 412, 1845. 3, Pearce, Proc. Col. Soc., **2**, 134, 1886. 4, Hillebrand, Am. J. Sc., **35**, 303, 1888.

| | | | $As_2O_5$ | $P_2O_5$ | CuO | $H_2O$ | $Fe_2O_3$ | |
|---|---|---|---|---|---|---|---|---|
| 1. | Cornwall | G. = 4·26–4·36 | 29·71 | 0·64 | 60·00 | 7·64 | 0·39 | CaO 0·50, $SiO_2$ 1·12 = 100 |

| 3. | Utah | G. = 4·36 | 29·10 | — | 61·45 | 7·29 | *tr.* | = 97·84 |
| 4. | " | G. = 4·38 | $\frac{2}{2}$ 29·59 | 0·05 | 62·44 | 7·72 | 0·12 | ZnO 0·05, $SiO_2$ 0·06 = 100·03 |

**Pyr., etc.**—Same as for olivenite.

**Obs.**—Occurs in Cornwall, with other ores of copper, at Ting Tang mine, Wheal Unity, and Wheal Gorland, and at Bedford United Mines, near Tavistock. The crystals usually present a very dark blue color and brilliant luster, but are rarely recognizable, being aggregated in diverging groups, or disposed in extremely minute individuals, in cavities of quartz; whence the name *aphanesite*, from ἀφανής, *unmanifest*. Also found (about 1825) with chalcophyllite at mines now abandoned near Saida in Saxony.

In Utah, Tintic district, at the Mammoth mine, in fine crystallizations, with other copper and iron arsenates associated with enargite.

Named *Clinoclasite* in allusion to the basal cleavage being oblique to the sides of the prism.

**Ref.**—[1] Min., 331, 1837; cf. Dx., Ann. Ch. Phys., **13**, 419, 1845; Schrauf, Atlas, xx.

### 572. CHONDRARSENITE. Kondroarsenit *Igelström*, Öfv. Ak. Stockh., **22**, 3, 1865.

In small embedded grains.

Brittle. Fracture conchoidal. H. = 3. Color yellow to reddish yellow. Translucent. Biaxial; optically —. Ax. angle large, Btd.[1]

**Comp.**—Perhaps $Mn_3As_2O_8.3Mn(OH)_2$ or $6MnO.As_2O_5.3H_2O$ = Arsenic pentoxide 32·5, manganese protoxide 59·9, water 7·6 = 100.

The analysis gives about ½ molecule more water than the above formula demands, and the mineral obviously needs further examination.

**Anal.**—Igelström, l. c.

$As_2O_5$ 33·50 MnO 51·59 MgO 2·05 CaO 4·86 $H_2O$ 7·00 $CO_2$ *tr.* = 99·00

**Pyr., etc.**—B.B. in tube decrepitates, blackens, and gives neutral water. On charcoal easily fusible to a black bead, not magnetic; in the inner flame gives arsenical fumes. With borax gives manganese reaction. Easily and completely soluble in dilute hydrochloric and nitric acids.

**Obs.**—Occurs in the Pajsberg mines, Wermland, Sweden, in veins of barite intersecting hausmannite.

Named from its similarity in occurrence, color, and transparency to chondrodite, while differing from it in being an arsenate.

**Ref.**—[1] Bull. Soc. Min., 8, 374, 1885.

XANTHARSENITE. Xanthoarsénite *L. J. Igelström*, Bull. Soc. Min., **7**, 237, 1884.

In grains and massive; optically biaxial (Btd.). Fragile. Color sulphur-yellow. Optically biaxial, +? Btd.

Near chondarsenite, but contains more water. Composition perhaps essentially $5MnO.As_2O_5.5H_2O$ = Arsenic pentoxide 34·1, manganese protoxide 52·5, water 13·4 = 100. Needs further examination. Anal.—Igelström.

| $As_2O_5(Sb_2O_5$[a]$)$ | MnO | FeO | MgO | CaO | $H_2O$ | |
|---|---|---|---|---|---|---|
| $\frac{2}{2}$ 33·26 | 43·60 | 3·11 | 6·08 | 1·93 | 12·02 | = 100 |

[a] Perhaps 3 p. c.

Occurs with hausmannite, also with hematite and magnetite in crystalline limestone at the Sjö mine, parish of Grythytte, Örebro, Sweden.

**573. DUFRENITE.** Strahlstein (var.) *Jordan*, Min., etc., Reisebem., 243, 1803. Grüneisenstein (strahlicher) *Ullmann*, Syst. Tab. Uebers., 152, 319, 1814. Faseriche Grün-Eisenerde *W.* Dufrenite *Brongn.*, Tabl., 20, 1833. Green Iron Ore. Kraurit *Breith.*, Handb., 152, 1841.

Orthorhombic. Axes (approx.) $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}8734 : 1 : 0{\cdot}4262$ Streng[1].
$100 \wedge 110 = 41° 8'$, $001 \wedge 101 = 26° 0\frac{2}{3}'$, $001 \wedge 011 = 23° 5'$.

**Forms**[1]: *a* (100, *i-ī*), *b* (010, *i-ĭ*); *m* (110, *I*), *l* (120, *i-2̆*)?; *e* (011, 1-*ĭ*).

Angles: *mm'''* = *82° 16', *ee'* = *46° 10', *ll'* = 59° 35'.

Crystals rare, small and indistinct in consequence of grouping; *e* much rounded, *a*, *b* vertically striated. Usually massive, in nodules; radiated fibrous with drusy surface.

Cleavage: *a*, probably also *b*, but indistinct. H. = 3·5–4. G. = 3·2–3·4; 3·227 Dufr. Luster silky, weak. Color dull leek-green, olive-green, or blackish green; alters on exposure to yellow and brown. Streak siskin-green. Subtranslucent to nearly opaque. Strongly pleochroic.

**Comp.**—Doubtful; in part (anal. 1, 2) corresponds to $FePO_4.Fe(OH)_3 = 2Fe_2O_3.P_2O_5.3H_2O$ = Phosphorus pentoxide 27·5, iron sesquioxide 62·0, water 10·5 = 100. Other analyses give somewhat different results.

The crystallized mineral of Waldgirmes corresponds nearly to $3FePO_4.2Fe(OH)_3$ or $5Fe_2O_3.3P_2O_5.6H_2O$ = Phosphorus pentoxide 33·2, iron sesquioxide 58·4, water 8·4 = 100. Ferrous iron is present only in small amount.

Further, some analyses show ferrous iron, and perhaps these kinds do not belong here. Anal. 8 gives $FeO.3Fe_2O_3.2P_2O_5.6H_2O$ (cf. chalcosiderite).

**Anal.**—1, Karsten [Arch., **15**, 243], Rg., 329, 1860. 2, Diesterweg, B. H. Ztg., **22**, 257, 1863. 3, Deichsel, Rg., Min. Ch., 316, 1875. 4, 5, Boricky, Ber. Ak. [a] Incl. 0·24 MnO.

**Pyr., etc.**—Same as for vivianite, but less water is given out in the closed tube. B.B. fuses easily to a slag.

**Obs.**—Occurs near Anglar, Dept. of Haute Vienne, and at Hirschberg in Westphalia (the localities of the specimens, according to Dufrénoy, originally named *dufrenite*); at Rochefort-en-Terre, Morbihan, France; Eiserfeld near Siegen. From the Rothläufchen mine near Waldgirmes; St. Benigna, Bohemia; East Cornwall, in crystals resembling those described by Streng (Miers); also in botryoidal form at Wheal Phœnix.

In the U. States, at Allentown, N. J., as a fibrous leek-green coating, sometimes half an inch thick, in the Green Sand formation; it changes to brown in altering to limonite. In Rockbridge Co., Va., in radiated coarsely fibrous masses of a dark greenish brown color, forming an irregular bed of about 10 inches in depth, underlying limonite.

Named after the French mineralogist, P. A. Dufrénoy (1792–1857). Kraurite is from *κραῦρος*, *harsh, dry*.

**Ref.**—[1] Jb. Min., **1**, 110, 1881.

**Pyr., etc.**—In the closed tube whitens and yields water. B.B. with cobalt solution the blue color of the mineral is restored. In the forceps whitens, cracks open, swells up, and without fusion falls to pieces, coloring the flame bluish green. The green color is made more intense by moistening the assay with sulphuric acid. With the fluxes gives an iron glass; with soda on charcoal an infusible mass. Unacted upon by acids, retaining perfectly its blue color.

**Obs.**—Occurs both massive and crystallized in narrow veins, traversing clay slate, in the torrent beds of Schladming and Rädelgraben, near Werfen in Salzburg, with siderite; in Graz, near Vorau; Krieglach, in Styria; at Hochthäligrat, at the Gorner Glacier, Rympfischwang, Upper Valais, Switzerland; also in veins or pockets in quartzyte, in Horrsjöberg, Wermland, Sweden massive and granular, sometimes in 8-sided crystals 6 inches long and 2 inches in diameter; in the iron mine of Westanå, in Scania, Sweden, massive, of a dark azure color; also at Tijuco in Minas Geraes, Brazil. At Gulabgarh, India (La Touche, Rec. G. Surv., 23, 59, 1890).

Abundant with corundum at Crowder's Mt., Gaston Co., N. C.; and in fine sky-blue crystals, often 1–1½ inch long and broad, on Graves Mt., Lincoln Co., Ga., 50 m. above Augusta, with cyanite, rutile, pyrophyllite, etc. In Keewatin, Canada, near the mouth of the Churchill river.

The name lazulite is derived from an Arabic word, *azul*, meaning *heaven*, and alludes to the color of the mineral.

**Ref.**—[1] Haid., Nat. Abhandl. Wien, 1, 169, 1847. [2] Gamper, Krieglach, Vh. G. Reichs., 118, 1877. [3] Dx., N. R., 142, 1867. [4] Lasaulx, Zs. Kr., 9, 424, 1884. [5] Lévy-Lcx., Min. Roches, 229, 1888.

**575. TAVISTOCKITE.** Hydrated Calcium-aluminic Phosphate (?) *A. H. Church*, J. Ch. Soc., 18, 263, 1865. Tavistockite *Dana*, Min., 582, 1868.

In microscopic acicular crystals, sometimes aggregated in irregular stellate groups, constituting a white pearly powder.

Fragile. Luster pearly. Color white. Transparent to translucent.

**Comp.**—$Ca_3P_2O_8.2Al(OH)_3$ or $3CaO.Al_2O_3.P_2O_5.3H_2O$ = Phosphorus pentoxide 30·5, alumina 21·9, lime 36·0, water 11·6 = 100.

**Anal.**—Church, l. c.

|---|---|---|---|
| 30·36 | 22·40 | 36·27 | 12·00 = 101·03 |

**Pyr., etc.**—B.B. becomes opaque. With cobalt nitrate gives a blue color. Difficultly soluble in acids.

**Obs.**—Occurs at Tavistock, Devonshire, in cavities with quartz crystals, pyrite, chalcopyrite, and childrenite.

**576. CIRROLITE.** Kirrolith *C. W. Blomstrand*, Öfv. Ak. Stockh., **25**, 202, 1868.

Compact, without a trace of cleavage.

H. = 5–6. G. = 3·08. Color pale yellow.

**Comp.**—Perhaps $Ca_3Al(PO_4)_3.Al(OH)_3$ or $6CaO.2Al_2O_3.3P_2O_5.3H_2O$ = Phosphorus pentoxide 41·8, alumina 20·0, lime 32·9, water 5·3 = 100.

**Anal.**—Blomstrand, l. c., after removal of 4·60 not dissolved in the acid solution, of which 3·17 was silica.

| ⅔ 41·17 | 20·54 | 0·91 | 2·24 | 0·11 | 0·21 | 29·37 | 5·06 = 99·61 |

**Pyr., etc.**—B.B. fuses very easily to a white enamel. With soda a manganese reaction. Decomposed on digestion in fine powder in hydrochloric acid.

**Obs.**—Occurs at the iron mine at Westanå, in Scania, Sweden.

Named from κιρρός, *pale yellow*.

**577. ARSENIOSIDERITE.** Arseniosiderite *Dufr.*, Ann. Mines, **2**, 343, 1842, C. R., **16**, 22, 1843. Arsenokrokit, Arsenocrocites, *Glocker*, Syn., 226, 1847.

Tetragonal or hexagonal? Optically uniaxial, negative, Lcx.[1] In fibrous concretions resembling cacoxenite; the fibers large and easily separable between the fingers.

H. = 1–2. G. = 3·520 Dufr.; 3·88 Rg. Luster silky. Color yellowish brown and somewhat golden. Pleochroic. Powder yellowish brown, rather deeper in color than that of yellow ocher.

**Comp.**—$Ca_3Fe(AsO_4)_3.3FeOH)_3$ or $6CaO.4Fe_2O_3.3As_2O_5.9H_2O$ = Arsenic pentoxide 37·8, iron sesquioxide 35·0, lime 18·3, water 8·9 = 100.

**Anal.**—1, Dufrenoy, l. c., recalc. 2, 3, Rg., Pogg., **68**, 508, 1846. 4, Church, J. Ch. Soc., **26**, 102, 1873.

[a] Incl. 1·35 $Mn_2O_3$.

**Pyr., etc.**—Like scorodite.

**Obs.**—Occurs in a manganese bed at Romanêche, near Mâcon, Department of Saone-et-Loire, France; also at Schneeberg, Saxony, with erythrite and roselite.

Named from *arsenic* and σίδηρος, *iron*. Changed to *arsenocrocite* (fr. κρόκη, *fiber*) by Glocker, because of a previous use of arsenosiderite (see p. 96).

**Ref.**—[1] Bull. Soc. Min., **9**, 3, 1886.

---

**578. ALLACTITE.** Allaktit *A. Sjögren*, G. För. Förh., **7**, 109, 1884; Öfv. Ak. Stockh., **41**, No. 3, 29, 1884.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 0·61278 : 1 : 0·33385$; $\beta = 84° 16\frac{2}{3}' = 100 \wedge 001$ H. Sjögren[1].

$100 \wedge 110 = 31° 22\frac{1}{3}'$, $001 \wedge 101 = 27° 12\frac{2}{3}'$, $001 \wedge 011 = 18° 22\frac{1}{2}'$.

| Forms[1]: | | | | |

| 4. " | 28·89 | 58·86 | 0·25 | 1·53 | 1·37 | 9·02 | = | 99·92 |

**Pyr.**—B.B. nearly infusible, reactions for arsenic and manganese. Loses water and becomes black at a low red heat. Easily soluble in acids.

**Obs.**—Found with other manganese arsenates, with magnetite, hausmannite, pyrochroite, fluorite, etc., in druses in a manganiferous dolomite at the Moss mine, Nordmark, Sweden. Also at Långban with manganiferous barite (2 p. c. MnO).

Named from *ἀλλάττειν, to change*, in allusion to its strong pleochroism.

**Ref.**—[1] G. För. Förh., **7**, 220, 1884, Zs. Kr., **10**, 114, 1885. [2] Knr., Zs. Kr., **10**, 83, 1884.

**579. SYNADELPHITE.** Synadelphit *A.* and *H. Sjögren*, G. För. Förh., **7**, 235, 382, 1884.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0·8582 : 1 : 0·9192$; $\beta = 90° = 001 \wedge 100$ H. Sjögren[1].

$100 \wedge 110 = 40° 38\frac{1}{6}'$, $001 \wedge 101 = 46° 58'$, $001 \wedge 011 = 42° 35\frac{1}{3}'$.

**Forms:** *a* (100, $i$-$\bar{i}$); *u* (230, $i$-$\frac{3}{2}$), *o* (120, $i$-$\grave{2}$); *i* (102, $-\frac{1}{2}$-$\bar{i}$), *e* ($\bar{1}02$, $\frac{1}{2}$-$\bar{i}$), *f* (111, $-1$), *d* ($\bar{1}11$, 1), *h* (786, $-\frac{4}{3}$-$\frac{8}{7}$), *g* ($\bar{7}86$, $\frac{4}{3}$-$\frac{8}{7}$).

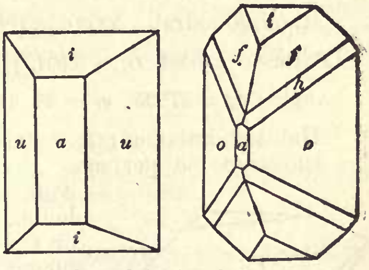
| | | | |
|---|---|---|---|
| *uu'* = 75° 41' | *ff'* = *76° 31' | *hh''* = 120° 31' | *if* = 36° 41' |
| *oo'* = 60° 27' | *ff''* = 109° 22' | *hh'''* = 74° 53' | *of* = 39° 34' |
| *ai* = 61° 50' | *f'f''* = *64° 12' | *ui* = 73° 10' | *ih* = 43° 7' |
| *ie* = 56° 20½' | *hh'* = 76° 37' | *oi* = 76° 15' | |

The form shows some resemblance to that of lazulite and liroconite, cf. Sjögren.

Crystals prismatic with *u*, *o*, vertically striated, also pyramidal with *f* (111) largely developed. Also in embedded grains.

Cleavage not observed. Fracture uneven to conchoidal. Brittle. H. = 4·5. G. = 3·45–3·50. Luster vitreous to greasy. Color brownish black to black. Feebly pleochroic. Nearly opaque. Optically +. Ax. pl. $\perp b$ and inclined 45° to $\grave{c}$. $Bx_a \perp b$. Ax. angle small.

**Comp.** — $2(Al,Mn)AsO_4.5Mn(OH)_2$. If Mn(Fe) : Al = 2 : 1, this requires: Arsenic pentoxide 28·3, alumina 4·2, manganese sesquioxide 12·9, manganese protoxide 43·5, water 11·1 = 100. Calcium and magnesium are also present in small amount.



Synadelphite, Sjögren.

**Anal.**—A. Sjögren, Zs. Kr., **10**, 146, 1885.

| $As_2O_5$ | $Al_2O_3$ | $Fe_2O_3$ | $Mn_2O_3$ | MnO | CaO | MgO | $H_2O$ | | |

| 29·31 | 6·16 | 1·23 | 11·79 | 35·71 | 3·76 | 2·19 | 11·39 | = | 101·54 |

**Pyr.**—Fuses easily on charcoal to a black slaggy bead: with soda gives arsenical reacts for manganese. Gives off water in the closed tube and becomes black. Dissolves readily in acids, giving off chlorine when warmed with hydrochloric acid.

**Obs.**—Occurs in a porous manganiferous limestone, often on barite, at the Moss mine, Nordmark, Sweden.

Named from σύν, *with*, ἀδελφός, *brother*, because intimately associated with other related species.

**Ref.**—[1] Zs. Kr., **10**, 143, 1885; the + and − signs attached to the planes are given provisionally, as the direction of obliquity is not fixed. Cf. Hamberg, G. För. Förh., **11**, 222, 1889.

**580. FLINKITE.** *A. Hamberg*, G. För. Förh., **11**, 212, 1889.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}41306 : 1 : 0{\cdot}73862$ Hamberg[1].
$100 \wedge 110 = 22^\circ\ 26\frac{2}{3}'$, $001 \wedge 101 = 60^\circ\ 47'$, $001 \wedge 011 = 36^\circ\ 27'$.

**Forms:** *c* (001, *O*), *b* (010, *i*-ĭ); *m* (110, *I*); *e* (101, 1-ī), *k* (111, 1). Also doubtful *p* (0·1·10, $\frac{1}{10}$-ĭ), *μ* (014, $\frac{1}{4}$-ĭ), *n* (027, $\frac{2}{7}$-ĭ).

Angles: *mm‴* = 44° 53′, *ee′* = 121° 34′, *ck* = *62° 40′, *kk′* = 110° 23′, *kk″* = 39° 39′, *bk* = *70° 10½′, *cμ* = 10° 28′, *cn* = 11° 55′.

In minute crystals, thin tabular ‖ *c*; faces *c* often striated ‖ *ă*, also *m*, *k*, *e* sometimes vertically striated. Crystals grouped in feather-like aggregates.

Brittle. H. = 4–4·5. G. = 3·87. Luster vitreous to greasy. Color greenish brown. Transparent. Strongly pleochroic: 𝔠 (= *a*) orange-brown, 𝔞 (= *b*) yellowish to brownish green, 𝔟 (= *c*) yellowish green. Optically +. Ax. pl. ‖ *c*. Bx ⊥ 100. Axial angle large; dispersion probably $\rho < v$.

**Comp.**—$MnAsO_4.2Mn(OH)_2$ or $4MnO.Mn_2O_3.As_2O_5.4H_2O$ = Arsenic pentoxide 30·5, manganese sesquioxide 22·3, manganese protoxide 37·6, water 9·6 = 100.

The composition is near that of synadelphite, and there is some resemblance in form, but, as shown by Hamberg, they can hardly be united.

**Anal.**—Hamberg, on 0·05 gr.

| $As_2O_5$ | $Sb_2O_5$ | $Mn_2O_3$ | $Fe_2O_3$ | MnO | MgO | CaO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 29·1 | 2·5 | 20·2 | 1·5[a] | 35·8 | 1·7 | 0·4 | 9·9 = 101·1 |

[a] Also $Al_2O_3$?.

**Pyr., etc.**—Same as synadelphite.

**Obs.**—Occurs with caryopilite and sarkinite at the Harstig mine near Pajsberg, Sweden.

Named after the Swedish mineralogist, Gustav Flink.

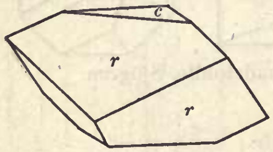
**581. HEMATOLITE.** Aimatolith *L. J. Igelström*, Öfv. Ak. Stockh., **41**, No. 4, 85, 1884, G. För. Förh., **7**, 211, 1884. Hämatolith. Diadelphit *H. Sjögren*, G. För. Förh., **7**, 233, 369, 1884, Zs. Kr., **10**, 130, 1885.

Rhombohedral. Axis $\dot{c} = 0{\cdot}8885$; $0001 \wedge 10\bar{1}1 = {}^*45^\circ\ 44'$ H. Sjögren[1].

**Forms**[2]: *c* (0001, *O*); *q* ($30\bar{3}4$, $\frac{3}{4}$), *r* ($10\bar{1}1$, *R*), *s* ($20\bar{2}1$, 2), *t* ($70\bar{7}3$, $\frac{7}{3}$)[2].

Angles: *cq* = 37° 35′, *cr* = 45° 44′, *cs* = 64° 1′, *qq′* = 63° 45½′, *rr′* = 76° 39′, *ss′* = 102° 15′.

Habit rhombohedral; *r* striated horizontally.



Cleavage: *c* perfect. Fracture uneven. Brittle. H. = 3·5. G. = 3·30–3·40. Luster vitreous to greasy, on cleavage face metalloidal. Color brownish red, garnet-red, becoming black on the surface. Streak bright chocolate-brown. Translucent when fresh.

Optically negative. Refractive indices: $\omega_r = 1{\cdot}723$, $\omega_v = 1{\cdot}740$ Sj. Exhibits striking optical anomalies, sometimes biaxial with small axial angle[3].

**Comp.**—According to Sjögren, $(Al,Mn)AsO_4.4Mn(OH)_2$. The manganese protoxide is in part replaced by magnesia. The percentage composition (Sj., calc.) is: Arsenic pentoxide 22·6, alumina 7·6, iron sesquioxide 1·2, manganese protoxide 48·9, magnesia 5·5, water 14·2 = 100.

**Anal.**—1, C. H. Lundström, Zs. Kr., **10**, 142, 1885. 2, A. Sjögren, ibid.

|  | $As_2O_5$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | CaO | MgO | $H_2O$ |  |
|---|---|---|---|---|---|---|---|---|
| 1. | 21·55 | 6·39 | 1·01 | 46·86 | 0·66 | 6·66 | 13·93 | insol. 0·64 = 97·70 |
| 2. | 22·54 | 8·61 |  | 50·98 | 0·71 | 5·38 | 14·02 | = 102·24 |

Igelström's analysis gave: $As_2O_5$ 25·70, MnO 34·55, FeO 13·05, MgO 8·10, CaO 2·52, $H_2O$ 16·08 = 100.

H. Sjögren argues that the manganese is chiefly present as sesquioxide.

**Pyr.**—B.B. does not fuse; gives off water and becomes black, on strong ignition becomes brown ($Mn_3O_4$). On charcoal gives arsenical fumes, and with soda a manganese reaction. Easily soluble in acids.

**Obs.**—Occurs in crystals lining cavities in a manganiferous limestone with magnetite, jakobsite, and fluorite at the Moss mine in Nordmark, Sweden.

Named from *αἷμα*, *blood*, in allusion to its color; diadelphite from *δις-*, *twice*, and *ἀδελφός*, *brother*, because of its close association with allactite. The former name has the priority.

**Ref.**—[1] L. c. [2] Lorenzen, Öfv. Ak. Stockh., **41**, No. 4, 95, 1884. [3] See Btd., Bull. Soc. Min., **7**, 124, 1884, who refers it to the monoclinic system, also Lorenzen and H. Sj.

**582. ARSENIOPLEITE.** *Igelström*, Bull. Soc. Min., **11**, 209, 1888, Jb. Min., **2**, 117, 1888.

Massive, cleavable (rhombohedral?). Optically uniaxial, positive. Color brownish red. Streak yellowish brown. Opaque in the mass. Transparent and blood-red in thin section.

**Comp.**—Perhaps $\overset{II}{R}_9\overset{III}{R}_2(OH)_6(AsO_4)_6$ or $\overset{II}{R}_3\overset{III}{R}(AsO_4)_2.\frac{3}{2}R(OH)_2$ or $9RO.R_2O_3.3As_2O_5.3H_2O$. $\overset{II}{R}$ = Mn,Ca, also Pb,Mg; $\overset{III}{R}$ = Mn, also Fe.

**Anal.**—Igelström, l. c.

| $As_2O_5$ | $Sb_2O_5$ | $Fe_2O_3$ | MnO | PbO | CaO | MgO | $H_2O$ |  |
|---|---|---|---|---|---|---|---|---|
| 44·98 | *tr.* | 3·68 | 28·25[a] | 4·48 | 8·11 | 3·10 | 5·67 | Cl *tr.* = 98·27 |

[a] Regarded as $Mn_2O_3$ 7·80, MnO 21·25.

It is believed that the manganese is present in part as sesquioxide, and the relation $Mn_2O_3$ 7·80, MnO 21·25 is suggested, but this is assumed somewhat arbitrarily and needs confirmation.

**Pyr.**—Decrepitates and on charcoal fuses B.B. easily, leaving a black slag, giving arsenical fumes, and a trace of a lead sublimate. Easily soluble in hydrochloric acid.

**Obs.**—Occurs at the Sjö mine, Grythytte parish, Sweden, with rhodonite in crystalline limestone; it forms thin veins or nodules.

Named irregularly from the Latin *arsenicum* and Greek *πλεῖον*, *more*, because it adds to the number of related minerals already described.

PLEURASITE *L. J. Igelström*, G. För. Förh., **11**, 391, 1889; Jb. Min., **1**, 253, 1890.

In masses of a bluish black color and opaque. H. = 4. Fracture conchoidal. Luster submetallic. Color bluish black, and streak black with a faint tinge of red. Opaque. Contains arsenic, a little antimony, manganese and iron protoxide, water; not analyzed. Occurs at the Sjö mine, Grythytte parish, Örebro, Sweden. It form bands, 1 cm. or less in thickness, on the side of arseniopleite, and is hence named from *πλευρά*, *side*.

---

**583. MANGANOSTIBIITE.** *L. J. Igelström*, G. För. Förh., **7**, 210, 1884; Bull. Soc. Min., **7**, 120, 1884. Hämatostibiite *Id.*, ibid., **8**, 143, 1886. Hematostibiite.

In embedded grains; orthorhombic?. Compact.

Color black. Streak brownish. Opaque.

**Var.**—The above characters apply to manganostibiite. Hematostibiite is blood-red in thin splinters. Optically −. Bx ⊥ cleavage. Ax. angle small. Pleochroic.

**Comp.**—Highly basic manganese antimonates. For manganostibiite the formula $10MnO.Sb_2O_5$ is suggested; for hematostibiite, $8MnO.Sb_2O_5$ or $9MnO.Sb_2O_5$. Arsenic may replace part of the antimony, and iron, etc., the manganese.

**Anal.**—1, 2, Igelström, l. c.

|  | $Sb_2O_5$ | $As_2O_5$ | MnO | FeO | CaO | MgO |  |
|---|---|---|---|---|---|---|---|
| 1. *Manganostibiite* | 24·09 | 7·44 | 55·77 | 5·00 | 4·62 | 3·00 | = 99·92 |
| 2. *Hematostibiite* | 37·2 | — | 51·7 | 9·5 | 1·6 |  | = 100 |

**Pyr.**—B.B. does not fuse, but gives an antimony coating on charcoal; with soda reacts for manganese. Dissolves completely in hydrochloric acid; with nitric acid gives a clouded solution.

**Obs.**—Manganostibiite occurs at Nordmark, Sweden, in crystalline manganesian limestone with other manganiferous minerals, as hausmannite, pyrochroite, allactite.

Hematostibiite is found at the Sjö mine, Grythytte parish, Örebro, Sweden, filling veins with calcite, also tephroite.

The following are other antimonates containing manganese, but imperfectly investigated and of doubtful relations:

FERROSTIBIAN *L. J. Igelström*, G. För. Förh., **11**, 389, 1889; Jb. Min., **1**, 250, 1890.

In monoclinic (?) crystals with *a* (100), *b* (010), *c* (001). Cleavage in two or three directions. H. = 4. Luster submetallic. Color black. Streak brownish black tending to red. Weakly magnetic. Anal.—Igelström, l. c.

$Sb_2O_5$ 14·80 FeO 22·60 MnO 46·97 MgO,CaO 2·14 $H_2O$ 10·34 $SiO_2$ 2·24 = 99·09

B.B. fuses on thin edges to a black magnetic glass. Gives antimony fumes on charcoal. Dissolves only imperfectly in acids.

Occurs embedded in massive rhodonite at the Sjö mine, Grythytte parish, Örebro, Sweden.

STIBIATIL *L. J. Igelström*, G. För. Förh., **11**, 391, 1889; Jb. Min., **1**, 254, 1890.

In prismatic crystals (monoclinic?) with rectangular and rhombic cross-section. H.= 5–5·5. Luster metallic. Color and streak iron black. Opaque. Not magnetic. Contains antimony, manganese, iron, water. An approximate analysis gave:

$Sb_2O_5$ 30 $Mn_2O_3$ 44 FeO 26 = 100

Occurs embedded in polyarsenite (sarkinite, p. 779) and associated with tephroite at the Sjö mine, Grythytte parish, Örebro, Sweden.

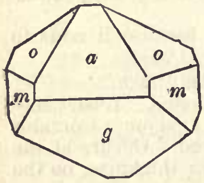
### 584. ATELESTITE. *Breithaupt*, Char. Min. Syst., 307, 1832.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0·9334 : 1 : 1·5051$; $\beta = {}^*70° \ 43' = 001 \wedge 100$ Busz[1].

$100 \wedge 110 = 41° \ 22\frac{5}{6}'$, $001 \wedge 101 = 44° \ 48\frac{1}{6}'$, $001 \wedge 011 = 54° \ 51\frac{1}{2}'$.

**Forms:** *a* (100, *i*-$\bar{i}$), *b* (010, *i*-$\grave{i}$), *c* (001, *O*), *l* (310, *i*-$\bar{3}$); *m* (110, *I*), *d* (101, − 1-$\bar{i}$), *g* ($\bar{1}$01, 1-$\bar{i}$), *e* (011, 1-$\grave{i}$), *o* (111, − 1), *q* (313, − 1-$\bar{3}$).

Angles: $ll''' = 32° \ 44'$, $mm''' = {}^*82° \ 45\frac{3}{4}'$, $cd = 44° \ 48'$, $cg = 72° \ 55\frac{1}{2}'$, $a'g = {}^*36° \ 21\frac{1}{2}'$, $ee' = 109° \ 43'$, $co = 53° \ 39'$, $oo' = 66° \ 40'$, $qq' = 24° \ 44'$.



In minute crystals tabular ‖ *a* and with *g* ($\bar{1}$01) also prominent; faces usually smooth and brilliant.

Cleavage: basal, indistinct. H. = 3–4·5. G. = 6·4 Busz. Luster adamantine. Color sulphur-yellow. Transparent to translucent.

**Comp.**—Basic bismuth arsenate, $H_2Bi_3AsO_8$ or $3Bi_2O_3.As_2O_5.2H_2O$ = Arsenic pentoxide 13·9, bismuth trioxide 83·9, water 2·2 = 100.

The composition is interpreted by Busz as either $(BiO)_2(Bi(OH)_2)AsO_4$ or (more probably) $BiAsO_4.2(BiO)OH$.

**Anal.**—K. Busz, Zs. Kr., **15**, 625, 1889.

$As_2O_5$ 14·12 $Bi_2O_3$ 82·41 $Fe_2O_3$ 0·51 $H_2O$ 1·92 = 98·96

**Obs.**—Occurs very sparingly on bismutoferrite, associated with erythrite at the Neuhilfe mine, Schneeberg, Saxony.

Named from ἀτελής, *incomplete*, presumably because its composition was unknown when first described. Breithaupt remarks upon the resemblance of the crystals to the Swiss titanite.

**Ref.**—[1] Zs. Kr., **15**, 625, 1889. Cf. earlier Rath (Pogg., **136**, 422, 1869), who made *g* = 205 and *o* = $\bar{1}$11.

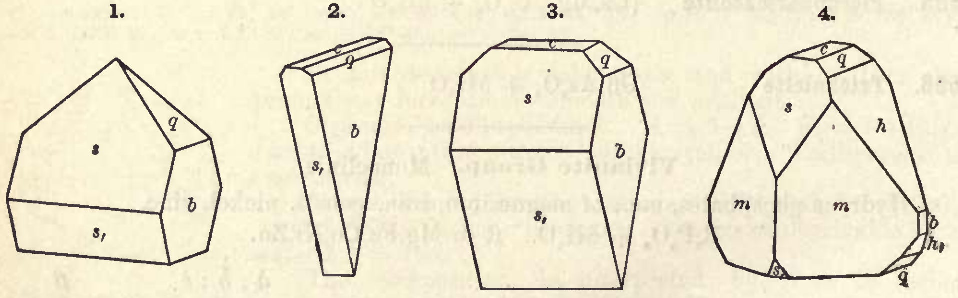

Fig. 1, Sadebeck. 2, 3, Kalkowsky. 4, Rath.

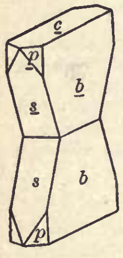
5.



Sadebeck.

Twins: tw. pl. *c* (f. 5). Habit varied: prismatic ∥ $\acute{c}$, or ∥ axis $\breve{a}$; also flattened ∥ *b*, or again ∥ *c*. Usually hemimorphic, the extremity terminated by the domes, *s* (101), *q* (011), etc., being the antilogous pole, and the basal plane, *c*, predominating at the analogous pole, cf. f. 1–4.

Cleavage: *c* sometimes perfect; *b* less so. Fracture conchoidal to uneven. Brittle. H. = 2. G. = 1·65–1·7. Color slightly yellowish to brown; white. Luster vitreous. Translucent; sometimes opaque. Tasteless, being but slightly soluble. Pyroelectric[3], see above.

Optically +. Ax. pl. ∥ *c*. Bx ⊥ *b*. Dispersion $\rho < v$ large. Axial angle variable, increased by heat, Dx.[6]

$2E = 59° 30'$ Mlr. $2E = 60° 30'$ Lang $2E = 60°$ Solly
$2E_r = 46° 32'$ $2E_y = 47° 30'$ $2E_v = 48° 46'$ Dx. $\beta_r = 1·497$ $\beta_y = 1·502$
Also $2E_r = 41° 49'$ at 6°·6 C., 43° 14′ at 21½°, 46° 4′ at 47°, 51° 50′ at 95°·5
$2E_r = 59° 40'$ Li $2E_y = 60° 56'$ Na, Kalkowsky[3]

**Comp.**—$NH_4MgPO_4 + 6H_2O$ = Phosphorus pentoxide 29·0, magnesia 16·3, ammonium oxide 10·6, water 44·1 = 100.

**Anal.**—1, Ulex, Jb. Min., 51, 1851, also other anals. 2, Pittman. Contr. Min. Victoria, 56, 1870. 3, Quoted by Rath, Ber. nied. Ges., 8, 1879. 4, MacIvor, Ch. News, **55**, 215, 1887.

**Pyr., etc.**—In the closed tube gives off water and ammonia and becomes opaque. B.B. colors the flame green, and fuses easily to an enamel which, heated with cobalt solution, assumes a beautiful purple color. Soluble in acids.

**Obs.**—Found in guano from Saldanha Bay, coast of Africa, embedded in patches of crystals; also under an old church in Hamburg, where quantities of cattle-dung existed in the soil above a bed of peat which contained the crystals. Also similarly at Homburg v. d. H. (Kalkowsky[3]). In the bat guano of the Skipton Caves near Ballarat in Victoria.

Named after the Russian statesman, v. Struve.

**Artif.**—A not uncommon artificial product, cf. Haushofer, l. c. Well-developed crystals of struvite have been obtained by Robinson in tubes of nutrient gelatin and agar-sugar, in which various micro-organisms were being cultivated; see Cambr. Phil. Soc., May 20, 1889; also Solly, ref.[4] below. Formed also from Koch's "Fleischpepton," Arzruni, ref.[5].

**Ref.**—[1] Hamburg, Min Mitth., 113, 1877; the position of Sbk. is here taken.

[2] See Sbk., l. c., for early literature, etc. On struvite from the Skipton Caves near Ballarat, Victoria, see Ulrich, Contr. Min. Vict., 1870, and Rath, Ber. nied. Ges., 10, 1878. On artif. cryst., see Haushofer, Zs. Kr., **4**, 43, 1880, also Solly, Arzruni, below. [3] Kalkowsky, Zs. Kr., **11**, 1, 1885. [4] Solly, on artif. cryst., Min. Mag., **8**, 279, 1889; possible tetartohedrism is suggested, cf. Sbk. [5] Arzruni. artif. cryst., Zs. Kr., **18**, 60, 1890. [6] Propr. Opt., **2**, 30, 1859; N. R., 95, 1867.

GUANO MINERALS. C. U. Shepard, Rural Carolinian, **1**, 470, 1870. The substances described occur in the guano of Guañape Island, 400 miles north-east of the Chincha Islands.

*Guanapite* occurs in irregular balls and veins looking like red rock-salt but having a rhombic cleavage. H. = 1–2. G. = 2·3. Soluble in 4–5 pts. of water at 60°. Taste bitter and saline. Analysis gave: Potassium sulphate 67·75, ammonium sulphate 27·88, ammonium oxalate 3·75 = 99·38. It loses ammonia on exposure to the air. Heated to redness leaves a residue of about 70 p. c. of potassium sulphate. It is near taylorite (p. 895) in composition. *Guanoxalate* is stated to be a pseudomorph of birds' eggs; the specimens are exteriorly white, "and seem to retain portions of the original shell, but these when tested seemed to be a mixture of phosphate and oxalate of lime." Within the substance is foliated and has a rhombic cleavage. Color cream white; luster pearly; translucent. H. = 1–2. G. = 1·58. When heated swells up, turns black, partially fuses, gives off ammonia fumes, and leaves a white residue of potassium sulphate. Composition stated to be potassium sulphate 40·20, ammonium oxalate 29·57, water 30·46 = 100·23—a very doubtful compound. *Oxammite*, *phosphammite*, and *biphosphammite* are other names given by Shepard for supposed new species consisting of ammonium oxalate, ammonium phosphate, and ammonium biphosphate.

*Epiglaubite* and crystallized *Glaubapatite* of Shepard (Am. J. Sc., **22**, 98, 99, 1856). One or the other of these may be metabrushite or brushite. On glaubapatite see p. 769.

*Epiglaubite* is described as occurring in "small aggregates or interlaced masses of minute semi-transparent crystals of a shining vitreous luster, which are always implanted on druses of glaubapatite, with H. = about 2·5," and as being "a largely hydrate phosphate, chiefly of lime, and may also contain magnesia and soda." It is not impossible that the mineral is metabrushite, although some characters are inconsistent with such a conclusion. If so, the name *epiglaubite* (meaning occurring implanted on glaubapatite) is inapplicable, and should be rejected.

*Redondite.* A name given by C. U. Shepard to a hydrous phosphate of aluminium and iron from Redonda, W. I. Found in nodular aggregations Translucent to opaque. Color grayish to yellowish white. H. = 3·5. G. = 1·90–2·07. Specimen analyzed contained: $SiO_2$ 8·8, $P_2O_5$ 40·19, $H_2O$ 24·73, Am. J. Sc., **50**, 96, 1870. An earlier analysis gave: $P_2O_5$ 43·20, $Fe_2O_3$ 14·40, $Al_2O_3$ 16·60, $H_2O$ 24·00, $SiO_2$ 1·60, CaO 0·57 = 100·37, contained also traces of $SO_3$, Na, Cl, and MgO. B.B. infusible. Heated with solution of cobalt gives a deep blue color. Am. J. Sc., **47**, 428, 1869.

DITTMARITE, MÜLLERITE *MacIvor*, Ch. News, **55**, 215, 1887. Stated to be new species from the guano of the Skipton Caves near Ballarat, Victoria.

**586. COLLOPHANITE.** Kollophan *Sandberger*, Jb. Min., 308, 1870. Monite *C. U. Shepard*, Am. J. Sc., **23**, 402, 1882.

Amorphous. Collophanite appears in layers resembling gymnite or opal, with conchoidal fracture; monite in slightly coherent masses, with earthy fracture. H. = 2–2·5; G. = 2·7, collophanite; 2·1, monite. Luster dull. Colorless or snow-white, yellowish white.

**Comp.**—$Ca_3P_2O_8 + H_2O$ or $3CaO.P_2O_5.H_2O$ = Phosphorus pentoxide 43·3, lime 51·2, water 5·5 = 100.

**Anal.**—1, Köttnitz, quoted by Sandberger, l. c.; 1*a*, same, after deducting calcium carbonate. 2, C. U. Shepard, Jr., after deducting 4·64 p. c. gypsum.

| 2. | Mona | 2·1 | 41·92 | 51·15 | — | 6·93 | = 100 |

[a] At 100°, 3·36 $H_2O$.

**Pyr., etc.**—Fuses with difficulty to a white enamel; gives off water in the closed tube; collophanite decrepitates violently B.B. Soluble in hydrochloric acid.

**Obs.**—Collophanite occurs on the island of Sombrero, having been formed in the elevated coral reef by infiltration of the salts from the overlying guano. Monite is found intimately associated with monetite, as also with gypsum and calcite, at the islands Mona and Moneta in the West Indies. Cf. monetite, p. 784.

*Collophanite* is named from *κόλλα, glue*, and *φαίνεσθαι*, to appear, in allusion to its colloidal aspect. *Monite* from the locality.

PYROPHOSPHORITE *C. U. Shepard, Jr.*, Am. J. Sc., **15**, 49, 1878.

Massive, earthy. H. = 3–3·5. G. = 2·50–2·53. Color snow-white, dull; also in part bluish gray, with small botryoidal structure. Analysis: Shepard after deducting impurities (about 2 p. c.):

$\frac{2}{2}$ $P_2O_5$ 51·67 CaO 45·16 MgO 3·17 = 100

The formula calculated is: $Mg_2P_2O_7 + 4(Ca_3P_2O_8 + Ca_2P_2O_7)$. Named in allusion to its apparent composition as a pyrophosphate; the nature of the material, however, makes its homogeneity seem very questionable. From the West Indies; exact locality not stated.

**587. HOPEITE.** *Brewster*, Trans. R. Soc. Edinb., **10**, 107, 1826 (1823). Prismatoidischer Zinkphyllit *Breith.*, Char., 38, 1832. Stilbite duovigésimale *Häuy*, cf. Dx., Bull. Soc. Min., **2**, 133, 1879.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c}$ = 0·5722 : 1 : 0·4717 Lévy[1].

100 ∧ 110 = 29° 46¾′, 001 ∧ 101 = 39° 30′, 001 ∧ 011 = 25° 15¼′.

**Forms:** *b* (010, *i*-$\breve{\imath}$) *x* (320, *i*-$\frac{\breve{3}}{2}$) *s* (120, *i*-$\breve{2}$) *e* (101, 1-$\bar{\imath}$)
*a* (100, *i*-$\bar{\imath}$) *c* (001, *O*) *m* (110, *I*) *u* (103, $\frac{1}{3}$-$\bar{\imath}$) *r* (111, 1)

*xx‴* = 41° 46′ *uu′* = 30° 44′ *ae* = *50° 30′ *rr′* = 73° 25′
*mm‴* = 59° 33′ *ee′* = 79° 0′ *cr* = 43° 31½ *rr‴* = *40° 0′
*ss′* = 82° 18′

Crystals minute, prismatic. Faces *b, s* striated vertically. Also in reniform masses, and amorphous.

Cleavage: *a* perfect; *b* less perfect. Fracture uneven. Brittle. H. = 2·5–3. G. = 2·76 Br.; 2·85 L. Luster vitreous; *a* somewhat pearly. Color grayish white; reddish brown when compact. Streak white. Transparent to translucent.

Optically –. Ax. pl. ∥ *c*. Bx ⊥ *b*. Dispersion $\rho < v$ weak. Ax. angles:

$2E_r$ = 78° 3′ glass $2E_y$ = 78° 35′ Na
$2H_{a.r}$ = 54° 47′ $2H_{a.y}$ = 54° 52′ also $2E_r$ = 84° 49½′ $2E_y$ = 85° 7′
$2H_{o.r}$ = 125° 52′ $2H_{o.y}$ = 125° 47′ ∴ $2V_r$ = 54° 39′ $2V_y$ = 54° 44′ $\beta_r$ = 1·469
$\beta_y$ = 1·471 Dx.

**Comp.**—Probably hydrous zinc phosphate, $Zn_3P_2O_8 + H_2O$ = Phosphorus pentoxide 35·2, zinc oxide 69·3, water 4·5 = 100.

The natural mineral has not been analyzed; the above is the composition of an artificial salt having the form (Dx., l. c.) of hopeite, Friedel and Sarasin, Bull. Soc. Min., **2**, 153, 1879.

**Pyr., etc.**—Dissolves without effervescence in hydrochloric or nitric acid. B.B. gives out water, and fuses with difficulty to a clear colorless globule, tingeing the flame green. With soda it affords a scoria which is yellow when hot, and gives out copious fumes of zinc and some of cadmium.

**Obs.**—Found in cavities in calamine at the zinc mines of Altenberg, near Aix-la-Chapelle. Named in honor of Prof. Hope of Edinburgh.

**Ref.**—[1] Ann. Mines, **4**, 517, 1843. Cf. also Haid., quoted by Brewster, l. c., and Dx., l. c.

---

### 588. DICKINSONITE. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **16**, 114, 1878.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 1{\cdot}73205 : 1 : 1{\cdot}19806$; $\beta = {}^{*}61° 30' = 001 \wedge 100$ E. S. Dana[1].

$100 \wedge 110 = 56° 41\frac{5}{6}'$, $001 \wedge 101 = 42° 13\frac{1}{6}'$, $001 \wedge 011 = 46° 28\frac{1}{2}'$.

**Forms:** *a* (100, *i-ī*), *c* (001, *O*); *x* (301, – 3-*ī*); *γ* (1̄03, ⅓-*ī*), *n* (051, 5-*ĭ*), *p* (1̄11, 1), *s* (2̄21, 2).

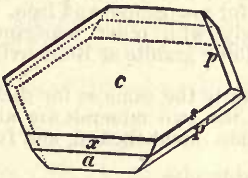
**Angles:** *cγ* = 12° 50′, *cx* = *42° 30′, *cn* = 79° 15′, *cp* = 61° 8½′, *cs* = 82° 2½′, *pp′* = 98° 40′, *ss′* = 118° 7′, Angle *a′cp* = *60°.

Crystals tabular, pseudo-rhombohedral; triangular striations on *c*. Commonly foliated to micaceous; also curved lamellar, radiated or stellated.

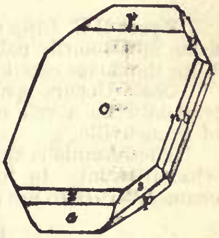
Cleavage: *c* perfect, separable into thin lamellæ. Fracture uneven. Brittle. H. = 3·5–4. G. = 3·338–3·343. Luster vitreous, on *c* somewhat pearly. Color olive- to oil-green, grass-green; slightly dichroic. Optically biaxial.

**Comp.**—$3R_3P_2O_8 + H_2O$ with R = Mn, Fe, $Na_2$ chiefly, also Ca, $K_2$, $Li_2$. The ratio for Mn : Fe(Ca) : $Na_2$ ($K_2$,$Li_2$) is closely 6 : 3 : 2, which requires: Phosphorus pentoxide 39·9, iron protoxide 16·5, manganese protoxide 32·6, soda 9·3, water 1·7 = 100.

1.



2.



**Anal.**—1, 2, H. L. Wells, Am. J. Sc., **39**, 214, 1890, upon material of established purity.

| | | $P_2O_5$ | FeO | MnO | CaO | $Na_2O$ | $K_2O$ | $Li_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 3·143 | 39·57 | 13·25 | 31·58 | 2·15 | 7·46 | 1·52 | 0·17 | 1·65 | quartz 2·58 = 99·93 |
| 2. | | 40·89 | 12·96 | 31·83 | 2·09 | 7·37 | 1·80 | 0·22 | 1·63 | quartz 0·82 = 99·61 |

Earlier analyses, 3, 4, by Penfield (quoted by Brush and Dana, l. c.) were made on much less pure material, they show more lime and water and less alkalies.

3, after deduction of impurities, viz., 3·30 p. c. quartz and 6·89 p. c. eosphorite; 4, after deducting 1·89 p. c. quartz, 6·89 p. c. eosphorite.

| | $P_2O_5$ | FeO | MnO | CaO | $Li_2O$ | $Na_2O$ | $K_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|
| 3. | 39·36 | 12·40 | 25·10 | 13·36 | 0·03 | 5·25 | 0·89 | 3·86 = 100·25 |
| 4. | 39·53 | 11·90 | 23·96 | [14·98] | 0·24 | 4·78 | 0·73 | 3·88 = 100 |

**Pyr., etc.**—In the closed tube gives water, the first portions of which are neutral, but the last portions react faintly acid; the residue is magnetic. Fuses in the naked lamp-flame, and B.B. in the forceps colors the flame at first green, then greenish yellow; reacts for iron and manganese with the fluxes. Soluble in acids.

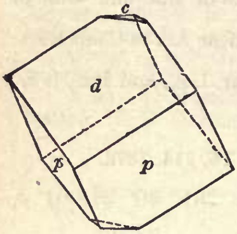
**Obs.**—Occurs at Branchville, Fairfield Co., Conn., intimately associated with eosphorite, triploidite, and other species in nests in a vein of albitic granite. Often disseminated in minute plates through massive eosphorite, giving it a green color; similarly embedded in lithiophilite. Named after Rev. Wm. Dickinson, formerly of Redding.

**Ref.**—[1] L. c., 1878. [2] Id., ibid., **39**, 213, 1890.

### 589. FILLOWITE. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **17**, 363, 1879.

Monoclinic. Axes $\breve{a} : \overset{|}{b} : \grave{c} = 1{\cdot}7303 : 1 : 1{\cdot}4190$; $\beta = 89° 50\frac{2}{3}' = 001 \wedge 100$ E. S. Dana.

$100 \wedge 110 = 59° 58\frac{1}{2}$, $001 \wedge \bar{1}01 = 39° 25'$, $001 \wedge 011 = 54° 49\frac{1}{2}'$.



**Forms:** *c* (001, *O*); *d* (201, – 2-$\bar{i}$), *p* ($\bar{1}11$, 1).

Angles: *cd* = *58° 31′, *cp* = *58° 40′, *pp′* = *95° 23′, *dp* = 95° $18\frac{1}{2}'$.

If *d* be made 100, the axial ratio becomes somewhat similar to that of dickinsonite, as shown below.

Habit pseudo-rhombohedral. In granular crystalline masses.

Cleavage: *c* nearly perfect. Fracture uneven. Brittle. H. = 4·5. G. = 3·43. Luster subresinous to greasy. Color wax-yellow, yellowish to reddish brown, colorless. Transparent to translucent. Optically biaxial, bisectrix ⊥ *c* approx.

**Comp.**—A hydrous phosphate of manganese, iron, calcium, and sodium, $3R_3P_2O_8 + H_2O$. If R = Mn : Fe(+Ca) : $Na_2$ = 6 : 2 : 1, this requires: Phosphorus pentoxide 39·6, iron protoxide 13·4, manganese protoxide 39·5, soda 5·8, water 1·7 = 100.

**Anal.**—1, Penfield, Am. J. Sc., **17**, 363, 1879. 2, H. L. Wells, ib., **39**, 215, 1890.

| | | $P_2O_5$ | FeO | MnO | CaO | $Na_2O$ | $Li_2O$ | $H_2O$ | quartz | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | $\frac{2}{3}$ | 39·10 | 9·33 | 39·42 | 4·08 | 5·74 | 0·06 | 1·66 | 0·88 | = | 100·27 |
| 2. | | 39·68 | 9·69 | 39·58 | 3·63 | 5·44 | 0·07 | 1·58 | 1·02 | = | 100·69 |

**Pyr.**—B.B. fuses at 1·5, with intumescence to a black feebly magnetic mass, coloring the flame momentarily pale green, then intensely yellow. In the closed tube a little neutral water. With the fluxes reactions for manganese and iron. Soluble in acids.

**Obs.**—Occurs sparingly with other manganesian phosphates, especially reddingite and triploidite, in a vein of albitic granite at Branchville, Conn. Named after Mr. A. N. Fillow, of Branchville.

The formula is apparently the same as for dickinsonite, but the ratio for the bases is somewhat different. In form the two minerals are also related, though widely diverse in physical characters. Both are pseudo-rhombohedral, and further we have:

| Dickinsonite. | Fillowite. |
|---|---|
| $001 \wedge 100 = 61° 30'$ | $001 \wedge 100 = 58° 31'$ |
| $001 \wedge \bar{1}11 = 61° 8'$ | $001 \wedge \bar{1}11 = 58° 40'$ |
| $001 \wedge \bar{1}\bar{1}1 = 61° 8'$ | $001 \wedge \bar{1}\bar{1}1 = 58° 40'$ |

Here *d* of fillowite is made 100, which gives the axial ratio, compared with that of dickinsonite:

| | | |
|---|---|---|
| Dickinsonite | $\grave{a} : \bar{b} : \acute{c}$ = 1·7320 : 1 : 1·1981 | $\beta$ = 61° 30′ |
| Fillowite | 1·7303 : 1 : 1·1093 | 58° 31′ |

---

## Roselite Group. Triclinic.

**590. ROSELITE.** *Lévy*, Ann. Phil., 8, 439, 1824; Edinburgh J. Sc., **2**, 177, 1825.

Triclinic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·45360 : 1 : 0·65604; $\alpha$ = 90° 34′, $\beta$ = 91°, $\gamma$ = 89° 20′ Schrauf[1].

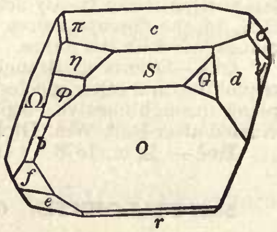
$100 \wedge 010 = 90° 39\frac{1}{2}'$, $100 \wedge 001 = 89° 0\frac{1}{2}'$, $010 \wedge 001 = 89° 26\frac{2}{3}'$.

**Forms**[1]:
*a* (100, $i$-$\bar{i}$)
*b* (010, $i$-$\breve{i}$)
*c* (001, *O*)
*n* (210, $i$-$\bar{2}'$)
*m* (110, *I′*)
*N* ($2\bar{1}0$, $'i$-$\bar{2}$)
*M* ($1\bar{1}0$, ′*I*)
*d* (401, ′4-$\bar{i}'$)

$\Delta$ ($\bar{4}01$, ′4-$\bar{i}'$)
*e* (023, $\frac{2}{3}$-$\breve{i}'$)
*h* (011, 1-$\breve{i}'$)
*f* (043, $\frac{4}{3}$-$\breve{i}'$)
*i* (021, 2-$\breve{i}'$)
*z* (083, $\frac{8}{3}$-$\breve{i}'$)
$\eta$ ($0\bar{2}3$, $'\frac{2}{3}$-$\breve{i}$)
$\chi$ ($0\bar{1}1$, ′1-$\breve{i}$)
$\phi$ ($0\bar{4}3$, $'\frac{4}{3}$-$\breve{i}$)

$\upsilon$ ($0\bar{2}1$, ′2-$\breve{i}$)
$\zeta$ ($0\bar{8}3$, $'\frac{8}{3}$-$\breve{i}$)
$\gamma$ (421, 4-$\bar{2}'$)
$\sigma$ (111, 1′)
$\omega$ (221, 2′)
$\lambda$ (343, $\frac{4}{3}$-$\frac{4}{3}'$)
*g* ($\bar{4}21$, ,4-$\bar{2}$)
*s* ($\bar{1}11$, ,1)
*o* ($\bar{2}21$, ,2)

*l* ($\bar{3}43$, ,$\frac{4}{3}$-$\frac{4}{3}$)
$\Gamma$ ($\bar{4}\bar{2}1$, 4-$\bar{2}$,)
$\Sigma$ ($\bar{1}\bar{1}1$, 1,)
$\Omega$ ($\bar{2}\bar{2}1$, 2,)
$\Lambda$ ($\bar{3}\bar{4}3$, $\frac{4}{3}$-$\frac{4}{3}$,)
*G* ($4\bar{2}1$, ′4-$\bar{2}$)
*S* ($1\bar{1}1$, ′1)
*O* ($2\bar{2}1$, ′2)
*L* ($3\bar{4}3$, $'\frac{4}{3}$-$\frac{4}{3}$)



After Schrauf.

Schrauf's lateral axes are exchanged in the above in order to bring out the close approximation to monoclinic symmetry.

$bm = 66° \ 9'$ $c\eta = 23° \ 43'$ $bo = 66° \ 0'$ $cS = 57° \ 26'$
$bM = 65° \ 3\frac{1}{2}'$ $e\eta = 47° \ 15'$ $b\Omega = 67° \ 22'$ $co = 73° \ 12\frac{1}{2}'$
$mM = 48° \ 47\frac{1}{2}'$ $b\sigma = 69° \ 53'$ $o\Omega = 46° \ 38'$ $cm = 88° \ 52'$
$cd = 79° \ 14'$ $b'S = 69° \ 30'$ $c\sigma = 56° \ 53'$ $cM = 89° \ 20'$
$ce = 23° \ 32'$ $\sigma S = 40° \ 37'$ $c\Omega = 73° \ 29\frac{1}{2}'$

Crystals small, often complex and, as explained by Schrauf, combined according to a number of twinning laws with embedded tw. lamellæ. Also in druses of crystals and in spherical aggregates.

Cleavage: macrodiagonal. H. = 3·5. G. = 3·5–3·6. Luster vitreous. Color light to dark rose-red. Transparent to translucent. Axes of elasticity sensibly parallel to crystallographic axes.

**Comp.**—$(Ca,Co,Mg)_3As_2O_8.2H_2O$ = Arsenic pentoxide 51·4, lime 28·1, cobalt protoxide 12·5, water 8·0 = 100 (Ca : Co = 3 : 1).

**Anal.**—Winkler, J. pr. Ch., **16**, 86, 1877.

| | | $As_2O_5$ | CoO | CaO | MgO | $H_2O$ |
|---|---|---|---|---|---|---|
| Daniel mine | G. = 3·56 | $\frac{2}{3}$ 52·67 | 10·29 | 25·05 | 4·10 | 8·29 = 100·40 |

Earlier analyses by Schrauf (on minute quantities), l. c., and Winkler (J. pr. Ch., **10**, **191**, 1874) gave somewhat different results. The crystals from the Rappold mine are darker in color and contain a little more cobalt with G. = 3·585; G. = 3·506 Daniel, Schrauf.

**Pyr.**—Heated to 100° becomes dark blue and splits up, but regains the red color on cooling. Fuses B.B. easily and on charcoal gives arsenical fumes; after roasting reacts for cobalt with the fluxes. Dissolves in acids.

**Obs.**—Early (1824) found at Schneeberg, Saxony, on quartz; later obtained from the same region at the Daniel and Rappold mines. Also reported from Schapbach, Baden.

Named after Gustav Rose (1798–1873).

**Ref.**—[1] Min. Mitth., 137, 1874; earlier but incomplete observations were made by Lévy and Haidinger, cf. Schrauf.

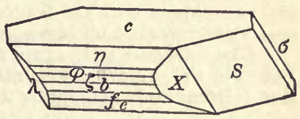
### 591. BRANDTITE. *A. E. Nordenskiöld*, Öfv. Ak. Stockh., **45**, 418, 1888.

Triclinic. In form near roselite.

**Forms**[1]:
$b$ (010, $i$-$\breve{\imath}$)
$c$ (001, $O$)
$e$ (023, $\frac{2}{3}$-$\breve{\imath}'$)
$f$ (043, $\frac{4}{3}$-$\breve{\imath}'$)
$\eta$ ($0\bar{2}3$, $'\frac{2}{3}$-$\breve{\imath}$)
$\phi$ ($0\bar{4}3$, $'\frac{4}{3}$-$\breve{\imath}$)
$\zeta$ ($0\bar{8}3$, $'\frac{8}{3}$-$\breve{\imath}$)
$\sigma$ (111, 1')
$\lambda$ (343, $\frac{4}{3}$-$\frac{4}{3}'$)
$S$ ($1\bar{1}1$, '1)
$X$ ($4\bar{3}3$, $'\frac{4}{3}$-$\frac{\bar{4}}{3}$)?

Approximate measured angles: $bc = 90° \ 35'$, $b\eta = 66° \ 55'$, $b\phi = 49° \ 46'$, $bf = 47° \ 2'$, $be = 65° \ 7'$, $bS = 69° \ 52'$.

In crystals, prismatic by development of the brachydomes, and with $c$ largely developed. Faces $c$ striated ‖ edge $c/\eta$. Twins common with $c$ as tw. pl. Crystals united in radiated groups and in rounded or reniform aggregates.



H. = 5–5·5. G. = 3·671–3·672. Luster vitreous. Colorless to white. Transparent to translucent.

**Comp.**—$Ca_2MnAs_2O_8 + 2H_2O$ or $2CaO.MnO.As_2O_5.2H_2O$ = Arsenic pentoxide 51·3, manganese protoxide 15·8, lime 24·9, water 8·0 = 100.

**Anal.**—G. Lindström, G. För. Förh., **13**, 123, 1891.

| $As_2O_5$ | $P_2O_5$ | MnO | PbO | FeO | CaO | MgO | $H_2O$ |
|---|---|---|---|---|---|---|---|
| 50·48 | 0·05 | 14·03 | 0·96 | 0·05 | 25·07 | 0·90 | 8·09 Cl 0·04, insol. 0·04 = 99·71 |

**Pyr., etc.**—Fuses rather easily to a brown bead; in the closed tube gives off water without decrepitation; arsenical fumes on charcoal. Dissolves in hydrochloric and nitric acids.

**Obs.**—Found at the Harstig mine, near Pajsberg, Wermland, Sweden. Associated with barite, calcite, caryopilite, sarkinite, and also crystallized native lead.

Named after the Master of the Mint, Georg Brandt (d. 1768).

**Ref.**—[1] Nordenskiöld, quoted by Lindström, l. c.

**592. FAIRFIELDITE.** *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **17**, 359, 1879. Leucomanganit *Sandberger*, Jb. Min., 370, 1879; **1**, 185, 1885.

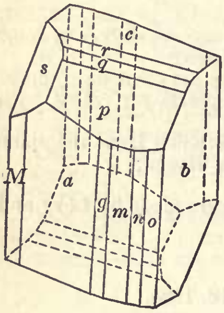
Triclinic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}2797 : 1 : 0{\cdot}1976$; $\alpha = 102^\circ\ 8\frac{2}{3}'$, $\beta = 94^\circ\ 33\frac{1}{3}'$, $\gamma = 77^\circ\ 19\frac{5}{6}'$ E. S. Dana.

$100 \wedge 010 = {*}102^\circ\ 0'$, $100 \wedge 001 = {*}88^\circ\ 0'$, $010 \wedge 001 = 78^\circ\ 33\frac{1}{3}'$.

**Forms:**
*a* (100, *i*-$\bar{i}$)
*b* (010, *i*-$\breve{i}$)
*c* (001, *O*)
*g* (320, *i*-$\frac{3}{2}$')
*m* (110, *I*')
*n* (230, *i*-$\frac{3}{2}$')
*o* (120, *i*-$\breve{2}$')
*M* (1$\bar{1}$0, '*I*)
*r* (113, $\frac{1}{3}$')
*q* (112, $\frac{1}{2}$')
*p* (111, 1')
*s* (1$\bar{4}$1, '4-$\breve{4}$

$ag = 10^\circ\ 57\frac{1}{3}'$ $aM = 14^\circ\ 45'$ $cm = 84^\circ\ 39'$ $bp = {*}78^\circ\ 30'$
$am = 16^\circ\ 31'$ $cr = 12^\circ\ 43'$ $ap = {*}56^\circ\ 30'$ $b's = 58^\circ\ 42\frac{1}{2}'$
$an = 24^\circ\ 40'$ $cq = 18^\circ\ 31'$ $as = 51^\circ\ 17'$ $ps = 42^\circ\ 47\frac{1}{2}'$
$ao = 32^\circ\ 20'$ $cp = {*}33^\circ\ 0'$

The relation in form between fairfieldite and roselite-brandtite is not clear; the fairfieldite measurements leave much to be desired.



In prismatic crystals with *a*, *b* largely developed. Usually in foliated to lamellar crystalline aggregates; occasionally curved, foliated, or fibrous; in radiating masses.

Cleavage: *b* highly perfect; *a* less so. Fracture uneven. Brittle. H. = 3·5. G. = 3·07–3·15. Color white or greenish white to pale straw yellow. Streak white. Luster pearly to sub-adamantine; on the surface of perfect cleavage (*b*) very brilliant, resembling selenite. Transparent.

The planes of light-vibration intersect *a* in lines making angles of 40° and 50° with the obtuse edge *a*/*b*; in the latter, an optic axis is visible toward the edge named. The planes intersect *b* in lines making angles of 10° and 80° with the edge *a*/*b*, the second axis visible in this plane.

**Comp.**—A hydrous phosphate of calcium and manganese, $Ca_2MnP_2O_8 + 2H_2O$ = Phosphorus pentoxide 39·4, manganese protoxide 19·6, lime 31·0, water 10·0=100. Iron replaces a little of the manganese.

**Anal.**—1, 2. S. L. Penfield, Am. J. Sc., **17**, 359, 1879; 1, clear transparent, filling cavities in reddingite; 2, massive, somewhat friable. 3, H. L. Wells, ib., **39**, 212, 1890.

| | G. | $P_2O_5$ | MnO | FeO | CaO | $Na_2O$ | $K_2O$ | $H_2O$ | quartz | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | | 38·39 | 15·55 | 5·62 | 28·85 | 0·73 | 0·13 | 9·98 | 1·31 | = | 100·56 |

**Pyr., etc.**—B B. glows, blackens, and fuses at 4·15 to a dark yellowish brown mass, coloring the flame pale green. with faint reddish yellow streaks on the upper edge. Reactions for iron and manganese with the fluxes. In the closed tube gives off neutral water; turns first yellow, then dark brown, and becomes magnetic. Soluble in acids.

**Obs.**—Occurs with other manganesian phosphates in a vein of albitic granite at Branchville, Fairfield Co., Conn. Also at Rabenstein, near Zwiesel, Bavaria (*leucomanganite*). In composition fairfieldite is analogous to roselite and more closely to brandtite.

---

**593. MESSELITE.** *W. Muthmann*, Zs. Kr., **17**, 93, 1889.

Triclinic. In indistinct minute tabular crystals, with *am* = 42°–43°; often in stellate aggregates.

H. = 3–3·5. Colorless to brownish. Transparent to translucent. Extinction on *a* inclined 20° to the edge *a*/*m*; an optic axis visible through *a*.

**Comp.**—$(Ca,Fe)_3P_2O_8 + 2\frac{1}{2}H_2O$ = Phosphorus pentoxide 38·3, iron protoxide 19·4, lime 30·2, water 12·1 = 100. Here Ca : Fe = 2 : 1. With $2H_2O$ the composition would correspond to brandtite and fairfieldite.

**Anal.**—Muthmann. l. c.

| $P_2O_5$ | FeO | MnO | CaO | MgO | $H_2O$ |
|---|---|---|---|---|---|
| 37·72 | 15·63 | *tr.* | 31·11 | 1·45 | 12·15 insol. 1·40 = 99·46 |

Gives off water when heated and becomes dark brown to black.

**Obs.**—Found near Messel in Hesse, in a coal mine; the crystals occur in a bituminous clay slate.

**594. REDDINGITE.** *G. J. Brush* and *E. S. Dana*, Am. J. Sc., **16**, 120, 1878; ib., **17**, 365, 1879.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·8678 : 1 : 0·9486$ E. S. Dana[1].

$100 \wedge 110 = 40° 57'$, $001 \wedge 101 = 47° 32\frac{5}{6}'$, $001 \wedge 011 = 43° 29\frac{1}{3}'$.

**Forms:** *b* (010, *i*-$\breve{i}$), *r* (112, $\frac{1}{2}$)[2], *s* (223, $\frac{2}{3}$)[2], *p* (111, 1), *t* (221, 2)[2], *q* (212, 1-$\bar{2}$).

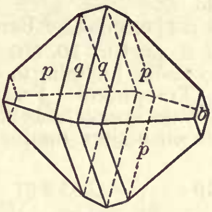
| $ss'' = 87° 57'$ | $tt' = 91° 6'$ | $qq''' = 35° 30'$ | $pt = 15° 35'$ |

Homœomorphous with scorodite and strengite.

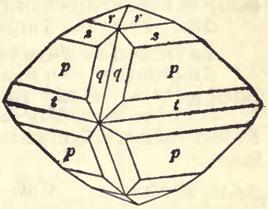
Habit octahedral; crystals often in parallel groupings. Also granular massive.

Cleavage distinct in one direction. Fracture uneven. Brittle. H. = 3–3·5. G. = 3·102. Luster vitreous to subresinous. Color pinkish white or pale rose-pink to yellowish white, surface sometimes dark reddish brown from alteration. Translucent to transparent.

1.



2.



**Comp.**—Hydrous phosphate of manganese, $Mn_3P_2O_8 + 3H_2O$ = Phosphorus pentoxide 34·7, manganese protoxide 52·1, water 13·2 = 100. Iron replaces part of the manganese; in anal. 3, Mn : Fe = 2 : 1.

**Anal.**—1, 2, H. L. Wells, quoted by Brush and Dana; 1, after deducting 12·08 p. c. quartz; 2, after deducting 4·42 p. c. quartz. 3, Id., ib., **39**, 212, 1890.

| | $P_2O_5$ | FeO | MnO | CaO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|

| 3. | 34·90 | 17·13 | 34·51 | 0·63 | — | 13·18 | quartz 0·13 = 104·48 |

**Pyr., etc.**—In the closed tube, first whitens, then turns yellow, and finally brown, but does not become magnetic. Fuses in the naked lamp-flame. B.B. colors the flame pale green, and fuses easily to a blackish brown non-magnetic globule. Reacts for manganese and iron with the fluxes. Soluble in acids.

**Obs.**—Occurs sparingly at Branchville, Fairfield Co., Conn., intimately associated with fillowite, fairfieldite, dickinsonite, in a vein of albitic granite. Black octahedral crystals, pseudomorphs after reddingite, are also found. Named from Redding, the name of the town in which the locality is situated.

In crystalline form, reddingite is closely related to scorodite and strengite, but differs from them in composition, containing but three equivalents of water, and having the metals in the protoxide state.

**Ref.**—[1] L. c., 1878. [2] Id., Am. J. Sc., **39**, 211, 1890; the symbols for *r* and *t* are given incorrectly.

**595. PICROPHARMACOLITE.** *Stromeyer*, Gilb. Ann., **61**, 185, 1819.

In aggregates of small spherical, botryoidal forms with radiating foliated structure. Luster feeble pearly. Color white. Opaque.

**Comp.**—$R_3As_2O_8 + 6H_2O$, with R = Ca : Mg = 5 : 1; this requires: Arsenic pentoxide 46·2, lime 28·1, magnesia 4·0, water 21·7 = 100.

**Anal.**—1, Stromeyer, l. c. 2, Frenzel, Jb. Min., 786, 1873. 3-5, Genth, Am. J. Sc., **40**, 204, 1890. The material of anal. 5 was dried over $H_2SO_4$ one month.

| | G. | $As_2O_5$ | CaO | MgO | $H_2O$ | | |

| 4. " | | 47·74 | 19·64 | 8·41 | 24·58 | | = |
| 5. " | | 50·56 | 17·09 | 11·54 | 20·35 | | = |

[a] At 100° loss 13 p. c. [b] Do. 11·6.

**Obs.**—From Riechelsdorf aud from Freiberg. At Joplin, Mo.
The name alludes to the magnesia present, from πικρός, *bitter*.

**596. TRICHALCITE.** Trichalcit *Herm.*, J. pr. Ch., **73**, 212, 1858.

In radiated groups, columnar; also in dendritic forms.

H. = 2·5. Luster silky. Color verdigris-green.

**Comp.**—$Cu_3As_2O_8 + 5H_2O$ = Arsenic pentoxide 41·3, cupric oxide 42·6, water 16·1 = 100.

**Anal.**—Hermann, l. c.

| $As_2O_5$ | $P_2O_5$ | CuO | $H_2O$ | |
|---|---|---|---|---|
| 38·73 | 0·67 | 44·19 | 16·41 | = 100 |

**Pyr., etc.**—Heated decrepitates, yields much water, and becomes dark brown. B.B. on charcoal fuses in the outer flame to a pearl, and in the inner yields a bead of copper. Dissolves easily in cold hydrochloric acid.

**Obs.**—From the Turginsk copper mine, or Berezov, on tetrahedrite. Resembles tyrolite.

LAVENDULAN *Breithaupt*, J. pr. Ch., **10**, 505, 1837. Lavendulite.

Amorphous, with a greasy luster, inclining to vitreous. H. = 2·5–3. G. = 3·014 Br. Color lavender-blue. Streak paler. Translucent. Fracture conchoidal.

Contains, according to Plattner, arsenic, cobalt, nickel, and copper. Goldsmith (Proc. Acad. Philad., 192, 1877) obtained on an impure sample from Chili, after deducting impurities (11·6 insol.):

| $As_2O_5$ | CuO | CoO | NiO | $H_2O$ | |
|---|---|---|---|---|---|
| 46·89 | 40·10 | 2·51 | 1·35 | 9·13 | = 99·98 |

The formula arrived at is $R_3As_2O_8.3H_2O$, but the material was too impure to make the conclusion very definite. B.B. fuses easily. Soluble in warm hydrochloric acid.

Occurs with cobalt and other ores at Annaberg, Saxony, as the result of their alteration. Similarly with cobalt ores from Chili.

CHLOROTILE. Chlorotil *Frenzel*, Min. Mitth., 42, 1875; Jb. Min., 517, 1875.

In minute capillary crystals of prismatic habit (orthorhombic), also fibrous and massive; soft. Color in the mass pale green to emerald-green, microscopic crystals colorless. Transparent. Composition asserted to be $Cu_3As_2O_8 + 6H_2O$ = Arsenic pentoxide 39·9, cupric oxide 41·3, water 18·8 = 100. An approximate analysis gave: $As_2O_5$ 41, CuO 41, $H_2O$ 18 = 100. Occurs with aragonite and wapplerite, at Schneeberg, and with quartz and scheelite at Zinnwald.

---

## **Vivianite Group.** Monoclinic.

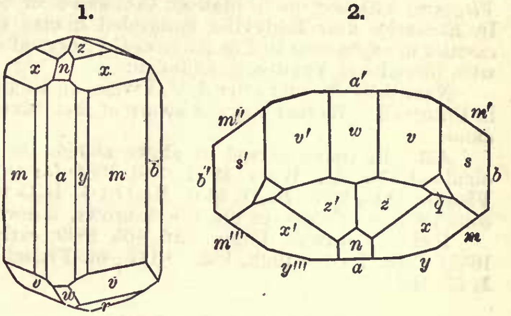
Crystals prismatic, sometimes flattened ‖ *a*; prismatic faces vertically striated. Crystals often in stellate groups. Often reniform and globular. Structure divergent, fibrous, or earthy; also incrusting.

Cleavage: *b* highly perfect; *a* in traces; also fracture$^s$ fibrous nearly $\perp \dot{c}$. Flexible in thin laminæ; sectile. H. = 1·5–2. G. = 2·58–2·68. Luster, *b* pearly or metallic pearly; other faces vitreous. Colorless when unaltered, blue to green, deepening on exposure. Streak colorless to bluish white, soon changing to indigo-blue; color of the dry powder often liver-brown. Transparent to translucent; becoming opaque on exposure. Pleochroism strong.



Figs. 1, 2, Cornwall, Rath.

Optically +. Ax. pl. and $Bx_o \perp b$. $Bx_{a.r} \wedge \dot{c} = 61^\circ\ 22'$. $Bx_{a.y} \wedge \dot{c} = 61^\circ\ 28'$. $Bx_{a.bl} \wedge \dot{c} = 61^\circ\ 36'$. Dispersion $\rho < v$ small, also horizontal inconsiderable. Axial angles, Dx.

$2H_{a.r} = 80^\circ\ 26'$ $\therefore\ 2E_r = 142^\circ\ 22'$ $2H_{o.r} = 121^\circ\ 19'$ $\therefore\ 2V_r = 73^\circ\ 4'$ $\beta_r = 1{\cdot}590$
$2H_{a.y} = 80^\circ\ 33'$ $\therefore\ 2E_y = 143^\circ\ 14'$ $2H_{o.y} = 121^\circ\ 10'$ $\therefore\ 2V_y = 73^\circ\ 10'$ $\beta_y = 1{\cdot}592$
$2H_{a.v} = 80^\circ\ 54'$ $\therefore\ 2E_v = 146^\circ\ 46'$ $2H_{o.v} = 120^\circ\ 52'$ $\therefore\ 2V_v = 73^\circ\ 26'$ $\beta_v = 1{\cdot}604$

**Comp.**—Hydrous ferrous phosphate, $Fe_3P_2O_8 + 8H_2O$ = Phosphorus pentoxide 28·3, iron protoxide 43·0, water 28·7 = 100.

Many analyses show the presence of iron sesquioxide due to alteration; see 5th Ed., p. 557.

Colorless crystals from Delaware gave Fisher (Am. J. Sc., 9, 84, 1850): $P_2O_5$ 27·17, FeO 44·10, $H_2O$ 27·95, $SiO_2$ 0·10 = 99·32.

Pale bluish green crystals from Cornwall (measured by Rath, above) gave Flight 1·13 $Fe_2O_3$; a dark blue variety contained 9·17 $Fe_2O_3$ and dark brown crystals 5·08 $Fe_2O_3$, Ch. News, **22**, 260, 1870.

A peculiar variety of vivianite has been described by W. L. Dudley (Am. J. Sc., **40**, 120, 1890) forming "blue roots" embedded in clay some two feet below the water surface near Eddyville, Ky. The roots were from ½ to 2 cm. thick and 6 to 12 in length, and the woody fiber had been nearly replaced by the vivianite. An analysis of material purified by washing and decantation and dried for twelve hours over sulphuric acid gave:

| $P_2O_5$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | CaO | MgO | $H_2O$(243°) | $H_2O$(100°) | insol. |
|---|---|---|---|---|---|---|---|---|
| 27·71 | 17·74 | 9·35 | 24·58 | 0·59 | 0·43 | 7·24 | 10·59 | 1·84 = 100·07 |

**Pyr., etc.**—In the closed tube yields neutral water, whitens, and exfoliates. B.B. fuses at 1·5, coloring the flame bluish green, to a grayish black magnetic globule. With the fluxes reacts for iron. Soluble in hydrochloric acid.

**Obs.**—Occurs associated with pyrrhotite and pyrite in copper and tin veins; sometimes in narrow veins with gold, traversing gray-wacke; both friable and crystallized in beds of clay, and sometimes associated with limonite, or bog iron ore; often in cavities of fossils or buried bones.

At St. Agnes in Cornwall transparent indigo crystals have been found, 1 inch in diameter and 2 in. long, in pyrrhotite; at Wheal Falmouth, and near St. Just; in Devonshire, near Tavistock; at Bodenmais and the gold mines of Verespatak in Transylvania, in crystals; on the promontory of Kerch in the Black Sea, in large indistinct crystals in the interior of shells. The earthy variety, sometimes called *blue-iron earth* or *native Prussian blue* (*Fer azuré*), occurs in Greenland, Syria, Carinthia, Cornwall, etc. The friable varieties in bog iron ore in several peat swamps in the Shetland Isles, at Ballagh in the Isle of Man, accompanying sometimes the horns of the elk and deer, and near an old slaughter-house in Edinburgh. At Cransac, France, in crystals formed after the burning of a coal mine; at Anglar, a massive form (*anglarite*).

In N. America, it occurs in *N. York*, at Harlem, in crystals accompanying stilbite and feldspar in fissures in gneiss In *New Jersey*, at Imleytown, in dark blue crystals; at Allentown, Monmouth Co., in considerable abundance, both crystallized, in nodules, and earthy, embedded in bog iron ore, and associated with clays; at Mullica Hill, Gloucester Co. (*mullicite*), in cylindrical masses, consisting of divergent fibers or acicular crystals; at Franklin, occasionally; it often fills the interior of belemnites and other fossils in the ferruginous sand formation. Also in *Delaware*, 4 m. W. of Cantwell's Bridge, and near Middletown, in the Green Sand, in fine large crystals which are colorless when first obtained, containing only iron protoxide; near Cape Henlopen, in Sussex Co. In *Maryland*, in the north part of Somerset and Worcester Cos. In *Virginia*, with bog ore in Stafford Co., and 8 or 10 m. from Falmouth, with gold and galena. In *Kentucky*, near Eddyville, embedded in clay (cf. above). In *California*, an earthy form in cavities in asphaltum in Los Angeles Co.; crystallized at Camptonville, Yuba Co. In *Canada*, with limonite at Vaudreuil, abundant.

Named by Werner after J. G. Vivian, an English mineralogist who discovered the specimens in Cornwall. Werner was not aware of their identity with the *Blaueisenerde* when he gave the name.

**Alt.**—Becomes altered, as above stated, through the oxidation of the iron. Tschermak obtained (Ber. Ak. Wien, **49** (1), 340, 1864) for an altered vivianite in crystals from a cabinet in Vienna: $P_2O_5$ 30·5, $Fe_2O_3$ 55·0, $Na_2O$ 1·5, $H_2O$ 14·0 = 101. G. = 2·95; luster metallic-pearly; color on face of cleavage pinchbeck-brown, elsewhere blackish brown; streak ocher-yellow.

**Ref.**—[1] Cornwall, Pogg., **136**, 405, 1869; earlier angles are incorrect. [2] Mlr., Min., p. 500, 1852; Rath, l. c. [3] Rath, l. c. [4] Dx., on French crystals, N. R., 184, 1867. [5] Mgg., Jb. Min., **1**, 53, 1884.

### 598. SYMPLESITE. *Breithaupt*, J. pr. Ch., **10**, 501, 1837.

Monoclinic. Axes $\grave{a} : \overset{\shortmid}{\bar{b}} : \grave{c} = 0·7806 : 1 : 0·6812$; $\beta = 72° 43' = 001 \wedge 100$ Krenner[1].

$100 \wedge 110 = 36° 42'$, $001 \wedge 101 = 33° 29\frac{1}{2}$, $001 \wedge 011 = 33° 2\frac{1}{2}'$.

**Forms**[1]: *a* (100, *i*-ī), *b* (010, *i*-ì), *c* (001, O); *m* (110, *I*); *r* (013, $\frac{1}{3}$-ì).

Angles: $mm''' = {}^*73° 24'$, $rr' = 24° 28'$, $br = {}^*77° 46'$, $mr = {}^*68° 56'$.

In small prismatic crystals sometimes tabular ‖ *b*; faces *m* vertically striated; in radiated spherical aggregates.

Cleavage: *b* perfect. Fracture uneven. Brittle. H. = 2·5 nearly. G. = 2·957. Luster of cleavage-face pearly; elsewhere vitreous. Color pale indigo, inclined to celandine-green; sometimes between leek- and mountain-green. Streak bluish white. Subtransparent to translucent.

Pleochroic: $\mathfrak{c}$ yellowish green to oil-green, ‖ $\mathfrak{b}$ colorless to greenish yellow, $\mathfrak{a}$ bluish green to blue. Optically −. Ax. pl. ⊥ *b* and inclined to $\grave{c} + 31° 48'$. $Bx_a \perp b$. $2H_{a.y} = 107° 28'$.

**Comp.**—Hydrous arsenate of iron, probably $Fe_3As_2O_8 + 8H_2O$ = Arsenic pentoxide 39·0, iron protoxide 36·6, water 24·4 = 100. The analysis gives $9H_2O$, which requires: Arsenic pentoxide 37·8, iron protoxide 35·5, water 26·7 = 100.

**Anal.**—Boricky, Vh. Min. Ges., **3**, 98, 1868, deducting 7·7 p. c. quartz.

| | | $As_2O_5$ | FeO | $H_2O$ | |
|---|---|---|---|---|---|
| Hüttenberg | G. = 2·964 | 37·84 | 34·73 | 27·43 | = 100 |

**Pyr., etc.**—In the closed tube yields much water; at a high temperature some arsenous acid sublimes, imparting an acid reaction to the water, and giving a black magnetic residue. B.B. in the forceps infusible, but colors the outer flame light blue (arsenic), and becomes black and magnetic. On charcoal gives a strong arsenical odor. With the fluxes reacts for iron, and gives also traces of manganese and sulphuric acid (Plattner).

**Obs.**—Occurs at Lobenstein in Voigtland, with siderite; at Hüttenberg, Carinthia; sparingly with pharmacosiderite at Pisek, Bohemia (Vrba). Also with quartz in cavities in hornstone at Felsöbánya.

Named from σύν and πλησιάζειν, *to bring together*, in allusion to its relation to other minerals.

**Ref.**—[1] [Term. Füz., 10, 83, 108, 1886] Zs. Kr., 13, 70; Jb. Min., 1, 462, ref., 1887.

**599. BOBIERRITE.** Phosphate de Magnésie tribasique et hydraté *Bobierre*, Les Mondes, 691, April 1868. Bobierrite *Dana*, Min., 595, 1868.

Monoclinic; in minute six-sided prismatic crystals, with *a* (100), *b* (010), *m* (110) and a terminal plane *c* (001)? inclined 77° to *a*. Forms crystalline agglomerations, looking like white spots in the guano in which it is embedded. Also massive.

Cleavage: clinodiagonal. Colorless to white. Optically +. Ax. pl. $\perp$ *b*. $Bx_a$ inclined 34° to *a*. $2E = 125°$ approx. Dispersion $\rho < v$ weak, Lcx.

**Comp.**—Hydrous magnesium phosphate, $Mg_3P_2O_8 + 8H_2O$ = Phosphorus pentoxide 29·5, magnesia 35·0, water 35·5 = 100.

**Anal.**—A. Lacroix, C. R., **106**, 631, 1888.

$P_2O_5$ 29·97 MgO 34·59 $H_2O$ 35·38 = 99·94

Insoluble in water, but easily soluble in acids without effervescence.

**Obs.**—From the guano of Mexillones, on the Chilian coast.

**600. HŒRNESITE.** Hörnesit *Haid.*, Vh. G. Reichs., 41, 1860; Ber. Ak. Wien, **40**, 18, 1860.

Monoclinic. In crystals resembling gypsum in habit, giving the angles: $mm''' = 73°$, $zz'(?) = 28°$ (cf. vivianite, p. 814). Also columnar; stellar-foliated.

Cleavage: clinodiagonal, perfect. H. = 1. G. = 2·474. Luster of cleavage pearly. Color snow-white. Folia transparent, flexible.

**Comp.**—Hydrous magnesium arsenate, $Mg_3As_2O_8 + 8H_2O$ = Arsenic pentoxide 46·6, magnesia 24·3, water 29·1 = 100.

**Anal.**—Hauer, quoted by Haidinger, l. c.

$As_2O_5$ 46·33 MgO 24·54 $H_2O$ 29·07 = 99·94

**Pyr., etc.**—In a glass tube gives much water. B.B. fuses easily, and on charcoal affords the odor of arsenic. Insoluble in water and easily soluble in acids.

**Obs.**—First distinguished by Kenngott in minerals from the Banat, Hungary (vicinity either of Cziklowa or Orawitza), in the Imperial Mineral Cabinet at Vienna. Occurs in a coarsely granular calcite, containing also some garnets.

Named after Dr. Hörnes, of the Imperial Cabinet.

**601. ERYTHRITE.** Kobold-Blüthe *Brückmann*, Magnalia, 161, etc., 1727. Kobolt Blomma, Flos Cobalti [the cryst.], Koboltbeslag [impure earthy], Cobalti minera colore rubro, etc., *Wall.*, Min., 234, 1747. Koboltblüte, Koboltbeschlag, Ochra Cobalti rubra, *Cronstedt*, 212, 1758. Kobaltblüthe *Germ.* Cobalt Bloom, Red Cobalt, Cobalt Ocher. Cobaltum acido arsenico mineralisatum *Bergmann*, Sciagr., 134, 1782, Opusc., **2**, 446, 1780 (first anal.). Arsenate of Cobalt. Cobalt arseniaté *Fr.* Erythrine *Beud.*, Min., **2**, 596, 1832. Rhodoise *Huot*, **1**, 313, 1841.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c} = 0·75 : 1 : 0·70$; $\beta = 75°$ approx., Brezina.[1]

**Forms**[2]: *a* (100, *i-ī*), *b* (010, *i-ì*); *m* (110, *I*), *w* ($\bar{1}01$, 1-*ī*); *r* ($\bar{1}12$, $\frac{1}{2}$), *v* ($\bar{1}11$, 1).

Angles nearly as with vivianite, measured: $m'v = 45°\ 48'$, $vw = 29°\ 43'$, $rr' = 34°\ 12'$.

Crystals prismatic and vertically striated. Also in globular and reniform shapes, having a drusy surface and a columnar structure; sometimes stellate. Also pulverulent and earthy, incrusting.

Cleavage: *b* highly perfect; *a*, *w* indistinct. Thin laminæ flexible[3] in a direction $\perp$ *b* and nearly $\perp$ *ċ*. Sectile. H. = 1·5–2·5; least on *b*. G. = 2·948. Luster of *b* pearly; other faces adamantine, inclining to vitreous; also dull and earthy. Color crimson- and peach-red, sometimes pearl-gray or greenish gray; red tints incline to blue $\perp$ *b*. Streak a little paler than the color; the dry powder deep lavender-blue. Transparent to subtranslucent.

Optically −. Ax. pl. and $Bx_a \perp b$. Axial angles, Dx.[3]:

$2H_r = 104°\ 41'$ $2H_y = 104°\ 31'$ $2H_{bl} = 102°\ 20'$

**Var.**—1. Crystallized and foliated. 2. Earthy. The latter is the *earthy cobalt bloom* (Kobaltbeschlag *Germ.*, Rhodoise *Huot.*).

**Comp.**—Hydrous cobalt arsenate, $Co_3As_2O_8 + 8H_2O$ = Arsenic pentoxide 38·4, cobalt protoxide 37·5, water 24·1 = 100. The cobalt is sometimes replaced by nickel, iron, and calcium.

**Anal.**—1–3, Kersten, Pogg., **60**, 251, 1843. 4, Lindaker, Vogl's Joach., 1857. 5, Petersen, Pogg., **134**, 86, 1868.
